In an address entitled "The Edinburgh Tradition and other Topics," Adami[1] emphasizes the great value of bedside teaching, more especially as carried out in the hospitals in Montreal, and he discusses the question why this method has been practiced so long in Montreal, while "elsewhere on the continent until recently clinical instruction and the free entry of students into the wards have been most exceptional?" "The democratic air of the states" is not considered adequate to explain the difference. The fact that many hospitals secondarily became attached to medical schools has been one cause, without doubt, of the opposition to the entrance of students into the wards. In Montreal the founders of the hospital and the earliest members of the staff were likewise the founders of the medical school, and they endeavored to exemplify in the new institutions the traditions of their youth. The Montreal school was developed by men from Edinburgh, and they continued the "Edinburgh tradition," that is, introduced the scheme of teaching in vogue for some time in Edinburgh. The men who founded the Montreal medical institution in 1823, and who became the medical faculty of McGill in 1829, were all Scotch. The Toronto school and the older schools in the United States were founded by English graduates. In London there was no regular instruction in the wards of hospitals until 1808. The Edinburgh school was well developed in 1750, and it was years in advance of London schools in the important matter of bedside instruction.

Adami quotes, from an old volume, notes showing that in 1780 there was in Edinburgh a well-developed system of practical clinical instruction. Gregory, Hume, Duncan, and other Edinburgh teachers, at the beginning of the nineteenth century, taught the men who in Montreal inaugurated a system of ward work that has given the McGill school an important standing on this continent. From this school have come men who have carried this tradition with them to other medical schools. This is an excellent illustration of the great influence that methods of instruction may exercise in the development of institutions. The influence of teachers and of methods of teaching go farther than merely to the present generation of students. As these scatter they are bound to carry with them the traditions and methods of their teachers. Hence the fundamental importance of guiding prospective medical students to those institutions whose methods and standards must be considered the best from the present point of view.

---

[1] Berliner Klin. Woch., 1900, No. 48, p. 1085.

[1] Montreal Med. Jour., 1900, xxix, 559-570.

"The democratic air of the States" has something to do with the establishment of proper methods of clinical instruction in our large public hospitals, in so far as the management of these institutions is after all an accurate index, not of any one class a little more intelligent than the rest, but of the main mass of the people. Wherever these institutions are managed according to the expediency of practical politics—and many of them unfortunately are so managed as yet— there the true interests of medical education are sure to suffer in some way or other. But perhaps more harm is done our medical students by the democratic air of the medical colleges themselves, many of which feel free to offer courses in medicine without any facilities whatsoever for adequate clinical instruction, giving no consideration to the lessons taught by the history of medical teaching in this and other countries. A conservative regard for traditions surely would have prevented the starting of medical schools under conditions that prevent them from being such otherwise than in name.

METHODS OF EXAMINATION BY STATE BOARDS AND HOSPITALS.

The various state boards and licensing bodies are entrusted with the important duty of determining to whom shall be granted the right to practice medicine and surgery. For this purpose examinations are held. As far as known all examinations of this kind are written; a series of questions are propounded in the various branches, the applicants write the answers, the papers are corrected and graded by the members of the examining body or their representatives, and if the marks when added reach a certain average, the necessary papers are granted. In practically all states the applicants for license must present evidence of having satisfactorily fulfilled certain requirements and conditions before they are admitted to the examination. In the majority of the states demanding special examination, these requirements include graduation from a medical college, and many states specify the colleges whose diplomas are "recognized" for this purpose. One of the weak points in this machinery is the character of the examination. Written examinations alone do not furnish the requisite basis for determining whether the applicant is a proper person to be given the right to practice even though he holds a diploma from a recognized college. The most that a written examination can do is to show something as to the degree of book-learning possessed by the applicant. No really satisfactory opinion of the practical training and practical knowledge attained by those examined is secured by this method. An applicant may be able to tell all about acute lobar pneumonia without ever having seen or studied a single actual case of the disease. He may describe with great fulness of detail the management of a serious case of labor without ever having seen the inside of a lying-in chamber. He may give the steps in the examination of sputum for tubercle bacilli without the slightest practical experience in clinical microscopic diagnosis. Much of the knowledge that is paraded in the written examinations may be of very recent acquisition, and undoubtedly it often is the result of a hasty process of cramming with the particular end in view of passing the examination.

It may be urged that the holding of a diploma from a recognized medical college guarantees a certain amount of practical fitness to engage in active professional work. Graduation from the better schools probably does. In some of the better schools practical examinations are now in vogue. But what significance in this line is to be given the diplomas of the much larger number of institutions without adequate equipment and with notoriously low standards? In order to remedy this serious defect in the state examinations their scope must be enlarged so as to include practical tests. Patients should be examined, diagnoses made, and treatment prescribed for the concrete actual case by the applicants. Practical laboratory manipulations, such as are used every day by the properly qualified practitioner, should be introduced as part of the examinations for license to practice. This is done in other countries and is done in the examinations for appointment to the medical corps of the U. S. Army and U. S. Marine-Hospital Service. Certainly the hospitals and public medical institutions of every state contain suitable materials for this purpose. And the examining boards surely can command the services of men competent to properly carry out the necessary tests. Examinations of this kind would be actual tests of the qualifications of those that apply for the right to practice. In the framing of new laws and the amendment of existing laws governing admission to practice in the various states this necessary improvement should be incorporated, if not practicable under the old rules, as it is plainly one of the next steps in the evolution of state regulation of medical practice.

The foregoing is applicable with additional force to hospitals that choose internes by competitive examination. Here it concerns not the mere grading of the applicants, but the more difficult problem of determining relative merit. The adequate solution of this problem demands practical examinations; for the competitor who possesses an equal amount of theoretical knowledge but greater practical training than his fellow-contestants is the one most worthy of appointment to the coveted position. In this way only can the best men be selected.

Practical, not theoretical, knowledge should be the qualification required. A man with a little book-learning and a good memory is on top under the present system; the man with brains, and with practical knowledge but without the ability to put it in words, is liable to be at the bottom.

WASHINGTON'S GOVERNOR AND MEDICAL PRACTICE.

The Governor of Washington has vetoed a medical practice act that passed the legislature, because it ruled out the osteopaths. The use of drugs, he claims, is the ruin of the race, and "the osteopaths are perhaps showing us a better way." It is a pity that a man has been elected to such high position, whose mental qualifications are such that he can not see the difference between legitimate medical practice and indiscriminate drugging, and no recourse from the latter but osteopathy or similar forms of quackery. He accuses physicians of "poisoning the springs of life," and calls "the contents of the drugstore perhaps more dangerous to the future well-being of the race than those of the saloon," this last being perhaps a politician's sop to the liquor trade. The spirit, however, of the extracts of the veto message that have been published, is generally that of a sanctimonious quack, who thinks he can libel an honorable class of fellow citizens with impunity from his official position. The members of the profession of the state of Washington should remember this insulting message, and like those of Colorado, previously mentioned in these columns, put an extinguisher upon the future political aspirations of their libeler.

MARK TWAIN AND OSTEOPATHY.

Some time ago the public was edified by the sensible humor and sarcasm of Mark Twain on the subject of "Christian Science." It is too bad that he, like other mortals, has his share of unwisdom, which he exhibits in recent remarks credited to him, endorsing osteopathy in particular and unlimited license in medical practice generally. He has lived so long abroad, it would seem that he is peculiarly jealous of personal liberty in America, a peculiarity often noticed in other individuals from foreign lands. His long residence in Vienna, where he apparently found matters temporarily satisfactory notwithstanding the police and other regulations, has apparently given him an appetite for license that he wants indulged. The state here, he says, stands for liberty, and without full freedom for osteopathy things would be as unsatisfactory as the garden of Eden was to Adam and Eve; people will want what they can not get. The comparison is not such a bad one, and the medical profession will not object if this view of the case, including the consequences, is considered by the legislators before whom he appeared in behalf of the frauds. Mark Twain is clearly a man with a somewhat kinky intellect, but it hardly seems that he will be taken seriously in his argument in behalf of those masseurs who call themselves osteopaths.

CALIFORNIA AND CHRISTIAN SCIENTISTS.

We were aware that the California legislature has had some queer propositions before it in the form of bills, and it therefore does not cause much surprise that it has followed the lead of some other state legislatures in putting "Christian Scientists" on an equality as regards medical practice with other recognized schools of medicine. The chief arguments that affected the intelligent legislators were that these scientists were a numerous and good class of people, which, as the *Sacramento Bee* says editorially, "would have been as pertinent regarding a bill enabling the inmates of the various lunatic asylums of the country to practice medicine." As that paper says, "it is doubtful whether the intelligent legislators who advocated and voted for the bill ever read any of Mrs. Eddy's books, or even know who she is"; and it gives for their benefit a little brief account of the "profitess" and her doctrine, that ought to enlighten them. It would be well if every legislature had near at hand so able and sensible an adviser on medical matters as have the California Solons in the *Sacramento Bee*.

THE DETERMINATION OF SEX.

Some day, perhaps, we may fully understand the mechanism underlying the determination of sex, but at the present time we must acknowledge the existence of certain deficiencies in this respect. Many hypotheses have been proposed, but no one satisfies all of the conditions, although each may contain some element of truth, and be based on the observation of some actual factor. Even apart from this circumstance, however, it seems probable that the process is not a simple one, but is dependent on a complexity of influences, at least some of which have been individually pointed out. On the basis of general knowledge, it seems probable that each parent contributes something in the determination of the sex of the offspring, and it appears likely that the final determining factor must be referred to some peculiarity in nutrition, affecting the spermatozoid, the ovum or the embryo, alone or severally. From this point of view, the hypothesis of Schenk would be most acceptable, though even it must be considered as crude and not sufficiently comprehensive. At a recent meeting of the Obstetrical Society of London, Dr. E. R. Dawson[1] read a paper on "The Essential Factor in the Causation of Sex," in which he took the ground that each ovary normally discharges ova independently of and probably alternately with the other, normal single pregnancy resulting from the fertilization of an ovum from one ovary only by the combined secretion of both testicles, the male parent thus not influencing the sex of the child, which depends rather on the ovary that supplies the ovum fertilized: if the right, a male; if the left, a female. Illustrative cases were cited in support of the view propounded. In the case of plural births, the sex of the children would be the same or different, accordingly as the fertilized ova were derived from one or both ovaries. Apparent exceptions to the rule were ascribed either to the grasping by the tube on one side of the ovary on the other side, or to the transmigration of ova. This hypothesis is not entirely new, nor probably is it correct. It seems most unlikely that the spermatozoid should be wholly without influence in sex determination, and it is scarcely more likely that what might be designated the accident of the situation of the ovary on the right or left side should have any decisive influence in this connection. As a matter of fact, some animals possess but a single ovary.

---

[1] British Med. Jour., Dec. 15, 1900, p. 709.

NEW SPECIFIC BLOOD REACTION.

A discovery of some importance from a medicolegal point of view is announced from Germany. Uhlenhuth[1] has found that by repeatedly injecting rabbits with defibrinated blood from various animals, a serum can finally be obtained which gives a specific turbidity with samples of the blood of other individuals of the same species. The blood samples to be tested must be diluted with water, to a pale red color, filtered or cleared by precipitation, and then have an equal amount of 1.6 per cent. solution of common salt added. This last is important, as without it the rabbits' serum gives, with water, a turbidity that might be confusing. Uhlenhuth has tested this reaction with human blood as well as with that of other animals, and in all cases obtained the specific reaction, the rabbits' serum failing to produce turbidity with any sample not taken from the species of animal from which it was inoculated. The test, moreover, is one of exceeding delicacy, the merest traces of blood serving to identify the animal from which they came. A specimen of dried stain on a board from a human being, ox, or horse, four weeks old, was enough when dissolved in salt solution. As regards the nature of the reaction, the author suggests the existence of a specific "coagulin" formed in the body, but whatever further research may prove so far as this is concerned, the importance of the discovery itself is manifest. It is to be hoped that this work will be followed up and confirmed by other workers.

THE YELLOW FEVER GERM.

There appears on another page the substance of the "interim report" of Dr. H. E. Durham and the late Dr. Walter Myers, the British yellow fever commission that has been investigating this disease in South America. Their discovery of a new claimant for the "germship," so to speak, of yellow fever, is an interesting addition to the sum of facts on the disease. The report was prepared before the authors had received any accounts of the later experiments of the American investigators in Cuba, as they remark that the man-to-man transference of yellow fever by a mosquito is hardly intelligible for bacillary disease and that it "does not seem to be borne out by the experiments." The incontestable evidence offered by Drs. Reed,[2] Carroll and Agramonte was evidently unknown to them, and it certainly does not specially favor a bacterial theory of the etiology. The American experimenters offer no positive theory as to the actual germ, however probable it might appear, from their results, that it is a protozoan, but as the case stands the conclusion that yellow fever is not due to such an organism can not be implicitly accepted. Nevertheless, the findings of Durham and Myers are to be taken as part of the sum of facts that is needed before the questions are solved, and they may have important side bearings on their solution. Like the American studies, they have cost a valuable life. Dr. Myers, like Dr. Lazear, is to be enrolled among the physicians who have sacrificed themselves in the search for knowledge that is needed for the good of mankind.

NEW HAMPSHIRE'S VITAL STATISTICS.

The Sixteenth Annual Report of the New Hampshire State Board of Health contains some interesting data regarding causes of death in that state, which are not altogether in accordance with prevailing notions as to the mortality. For example, consumption, which is as a rule considered to stand at the head of fatal diseases, falls from first to second place in 1898 and to fourth in 1899, pneumonia, heart disease, apoplexy and paralysis exceeding it in the number of their victims. Moreover, while it has held first place every other year since that state has had any accurate system of registration, excepting in the year 1892, there has been a steady decrease in its fatality, from 24.18 per 10,000 living population in 1884 to 14.43 in 1899, and its percentage of the total mortality has fallen from 14.01 to 8.26. This decrease also begins to appear from the first and before the microbic origin of the disorder was generally recognized, and therefore can only in part be attributed to special precautions based on that knowledge. The State Board is inclined to credit the decrease of mortality from this disease largely to better sanitation, ventilation, etc., of late years, as well as to the dissemination of information regarding it, in which it has been especially active of late. Pneumonia, on the other hand, is a disorder that has an increasing, as phthisis has a decreasing, mortality, and this is particularly aggravated in certain years by the prevalence of influenza. The average deathrate from pneumonia, between 1884 and 1899 inclusive, is 617, but this has been exceeded every year but two since 1889. The increase in mortality from cardiac and nervous disorders is likewise notable, the number of deaths from the former, prior to 1893, having been between 400 and 500, while since that date between 600 and 700 have been annually recorded. Of nervous diseases collectively, the average mortality for the past sixteen years has been 949, with a gradually increasing proportion, till in 1899 the deaths from these causes reached a total of 1111, the highest ever reported. Cancer statistics, contrary to experience in some other regions, have been remarkably uniform, with an annual average somewhere between 200 and 300. New Hampshire is supposed to be a typical New England commonwealth and, therefore, its statistics are of special interest. It has, however, few large towns, and its population is more largely rural than with its southern neighbors, which fact is to be considered. The decreased mortality from consumption is both welcome and significant, and the increase in that from pneumonia is in accordance with experience in some other sections. While the influenza epidemics of 1890 and 1899 may have had their influence, the increase was, from the figures, already apparent before the earliest of these dates. It seems not altogether unlikely that, with greater care, largely in personal hygiene and general sanitation, the "great white plague" may permanently take a less prominent place in the list of scourges to the human race, but new questions and diseases will then arise, and pneumonia, carcinoma, cardiac and nervous and other disorders appear in our mortality lists with more formidable frequency. Probably the sanitary golden age is still almost as far in the dim future as ever.

---

[1] Deutsch Med. Woch., February 7.

[2] Journal A. M. A., February 16.

Medical News.

CALIFORNIA.

Sanitary inspectors are now detailed by the State Board of Health to inspect all incoming trains from the South and East, at Oakland.

Merritt Hospital, Oakland, is to be located on a site—about 5½ acres on Hawthorne Avenue—secured by the trustees of the hospital.

CONNECTICUT.

Yale Medical School, New Haven, has received an anonymous donation of $100,000 which is to be applied to the construction of a clinical building—a laboratory of clinical medicine and surgery.

Dr. William R. Tinker, South Manchester, has been appointed by the coroner of Hartford county, medical examiner for the town of Manchester to fill the vacancy caused by the death of Dr. Julian N. Parker.

The State's death-rate for January was 19 per 1000 per annum. Infectious diseases caused 16.4 per cent. of the deaths, which numbered 1439, or 173 more than the average for the month for the five preceding years.

Incipient tuberculosis is to be treated in a state institution, especially provided, if a bill introduced in the legislature becomes a law. The bill, which has received the unqualified support of the New Haven Medical Society, provides for the establishment of a state hospital in some suitable locality for the treatment of incipient pulmonary tuberculosis, and appropriates $100,000 for the purchase and the erection of buildings.

DISTRICT OF COLUMBIA.

An unlicensed practitioner has been arrested at Washington, while passing under an assumed name, for practicing medicine without a license.

Tributes to deceased members of the Medical Society of the District of Columbia—Drs. Rosier Middleton and William P. Manning—were presented and adopted at a recent meeting of the Society.

Emergency Hospital changes include the appointment of Dr. Clifford Spiro as resident physician, vice Dr. W. R. Moulden; Dr. R. S. Beale, promoted to senior assistant, and Dr. Boyd Dixon, appointed junior assistant, as the result of a competitive examination.

An Examining Board consisting of Col. Alfred A. Woodhull, assistant surgeon general, U. S. A., Major Louis A. Le Garde, surgeon, U. S. A.; Capt. William C. Borden, assistant surgeon, U. S. A., and Capt. Frank R. Keefer, assistant surgeon, U. S. A., designated by the Secretary of War, met at Washington, February 11, to examine candidates for admission to the medical corps of the army. Medical boards have been ordered to convene at San Francisco and Manila, P. I., for a similar purpose.

ILLINOIS.

Dr. William Jayne, Springfield, has been appointed a member of the State Board of Charities, vice R. D. Lawrence, deceased.

Senator Busse has introduced a bill amending the inheritance tax law by providing that when beneficial interest passes to a hospital or other charitable institution, it shall not be subject to tax, but that the exemption shall not apply to institutions operated for profit.

Chicago.

Dr. Frederick C. Schaefer has been appointed gynecologist to St. Elizabeth's Hospital, and surgeon-in-chief to St. Hedwig's Hospital.

Dr. John H. Reeves, who was one of the defendants in the fraudulent insurance case, in which Dr. Michael N. Regent was recently convicted, has turned state's evidence and will testify in the third trial which is now in progress.

The deaths for the week ended March 2 were 434, or 87 fewer than the preceding week, and 103 less than the corresponding week of 1900. As compared with the corresponding period of a year ago, there were 68 fewer deaths from the acute pulmonary diseases and from diphtheria. There were only 9 from diphtheria during the week, as against 32 a year ago. Of these deaths, 165 were due to diseases of the respiratory system.

A coroner's jury has decided, in the case of a decedent who fell, breaking five ribs, and was given treatment by the Dowie method, that if medical aid had been rendered the deceased he would have recovered from his injuries and would certainly have been spared the physical agonies he suffered. It also recommends that a law be enacted which will compel medical examination by licensed physicians in cases of accident or external violence.

The smallpox situation is substantially unchanged; of 21 "suspect" cases reported, 11 were found to be smallpox and were removed to the Isolation Hospital, their premises were quarantined and disinfected, and all persons in the respective neighborhoods were vaccinated. Since the ripening of the vaccin lymph, systematic vaccination of the lodging-house districts has been resumed. At the close of the week there were 35 cases under treatment in the hospital, 9 had been discharged and none died.

February Mortality.—The total deaths for February numbered 1933, giving an annual death-rate of 14.32 per 1000, as against an annual rate of 15.21 per thousand for February, 1897. As compared with the preceding month there were 307 fewer deaths during February, and as compared with the corresponding month of a year ago there were 172 fewer. The reduction was chiefly in the deaths from pneumonia, bronchitis and influenza, there being 184 fewer deaths from pneumonia, 41 less from bronchitis, and 54 less from influenza, a total of 279 from these three diseases. There was also a lesser mortality from cancer, typhoid fever, diphtheria and from violence.

INDIANA.

The Wood medical bill, with an amendment excluding practicing osteopaths who are graduates of regularly constituted osteopathic schools, passed the senate, February 21.

Indiana deaths for January numbered 3400, 602 more than for January, 1900. The tuberculosis mortality increased 23 per cent. over the previous month, and respiratory diseases and measles and puerperal infection were more prevalent.

The Methodist State Hospital, Indianapolis, will be built on Twenty-ninth street, near Illinois, as soon as the executive committee secures subscriptions sufficient to warrant beginning the work. The intention is to begin with a small building and to enlarge as the needs of the institution increase.

IOWA.

Dr. Alpheus A. Deering, Boone, while on a trip in California, fell and broke his leg, February 18, and is now under treatment at Palo Alto.

The Cedar Valley Sanatorium has been established and will soon be opened at Cedar Rapids, under the medical directorship of Dr. George D. Sitzer.

Smallpox in the county jail, Des Moines, has caused the abandonment of the courts and county offices located in the building, and the quarantining of the entire structure.

KENTUCKY.

The Kentucky State Medical Society will hold its forty-sixth annual session in Louisville, May 22, 23 and 24.

Free public baths for Louisville have been reported on favorably by the committee of the board of aldermen and $5000 appropriated for the purpose.

Dr. E. C. Dudley, of Chicago, was the guest of Dr. William H. Wathen, Louisville, February 25, and held a clinic in the hospital of the Kentucky School of Medicine.

The formal opening of the hospital for the medical department of the University of Louisville occurred February 21.

The hospital is already in successful operation, and has accommodation for about fifty patients.

LOUISIANA.

The medical department of the New Orleans University (colored) held its annual commencement, February 26, graduating two.

A quarantine proclamation was formulated by the State Board of Health, February 25, governing all vessels engaged in the fruit-importing trade.

Fifty thousand dollars has been donated the Charity Hospital, New Orleans, by some unknown philanthropist, through Dr. Rudolph Matas. It was given unconditionally, for the purpose of increasing the nursing staff in the hospital and providing a suitable building to be used as a trained nurses' home.

Charity Hospital.—At the annual meeting held February 4 the Charity Hospital, New Orleans, elected the following officers: Dr. Ernest S. Lewis, vice-president; Dr. Jefferson D. Bloom, house surgeon; Dr. Erasmus D. Fenner, first assistant; Dr. James M. Batchelor, second assistant; Dr. Oliver L. Pothier, pathologist, and Dr. Maurice J. B. Couret, assistant pathologist.

Appointments.—The State Board of Health has appointed Dr. Fred Turney, Rigolets Station, and Dr. George H. Douglas, Atchafalaya Station, quarantine physicians, and the following as resident medical inspectors: Dr. J. L. Fridge, Belize, British Honduras; Dr. Augustus Smith, Livingston, Gautemala; Dr. J. S. Allison, Port Cortez, Spanish Honduras; Dr. King Holt, Bluefields, Nicaragua; Dr. Percy Ahrons, La Ceiba, Spanish Honduras; Dr. Allen Jumel, Port Limon, Costa Rica; and Dr. L. A. Wailes, Bocas del Toro, United States of Colombia.

MAINE.

The State Hospital at Augusta, which has a capacity of 500 insane, now has 767 such patients.

Dr. E. H. Wheeler, Camden, has been appointed assistant surgeon in the U. S. Volunteer service, with rank of captain.

Dr. Philip H. S. Vaughan, Augusta, has been selected as assistant superintendent of the Eastern Maine Insane Hospital at Bangor.

The State Medical Association, on account of the conflict of dates with the meeting of the AMERICAN MEDICAL ASSOCIATION, has changed the time for its annual session to June 12-14.

MICHIGAN.

Deaths in Michigan, for February, numbered 3173 or 498 more than for the preceding month. The increase is assigned to the prevalence of pneumonia and influenza.

The Semicentennial of the medical department of the state university was celebrated February 22. Dr. William F. Breakey, Ann Arbor, spoke on "Medical Education in the Early Fifties," and Dr. Victor C. Vaughan, dean, considered the ideals of the medical department.

Smallpox Infected Mail.—The State Board of Health has received a report from a health officer giving an instance where smallpox was apparently contracted by the handling of infected mail. There is but one case of the disease in that city, and that person has not been away from the city; he has been distributing mail, and the health officer suggests that as the mail carriers, when sorting mail, moisten their thumbs in their months, the only probable source of the disease is some infected letter handled in that manner.

MINNESOTA.

Bethesda Hospital, St. Paul, reports receipts of $132,291 for the nine years of its existence, and $79,944 disbursements. The buildings are valued at $56,990.

Dr. Samuel Friedlander, Minneapolis, who sued for $5050 for false arrest, and damage to his reputation as a physician and citizen thereby, was awarded $175 damages, February 20.

MISSOURI.

Dr. Thompson E. Potter, St. Joseph, was seriously injured in a runaway accident, February 24.

Dr. E. Victor Wedding, Kansas City, who was sued by a patient, for $2000 for alleged malpractice, had a verdict rendered in his favor, February 14.

Dr. Robert L. Evans, Boonville, has been made a member of the Cooper County court, under the provision of the new law which makes the county court ex-officio members of the State Board of Health.

NEW JERSEY.

Vaccination is progressing rapidly at Woodbury; the two cases of smallpox are doing well, and the health board does not anticipate any further spread of the disease.

Muhlenberg Hospital, Plainfield, has been given a site for its new building, with 500 feet frontage and a depth of 300 feet, by James A. Martine. The land is valued at $10,000.

Friction between the house staff and the superintendent of the Orange Memorial Hospital has culminated in the resignation of Drs. Frank H. Glazebrook and Henry P. Merrill, February 25.

Christ Hospital, Jersey City, in its twenty-seventh annual report shows that 4633 patients were cared for, 1171 of whom were bed patients in the hospital. The mortgage debt was reduced $3000 during the year.

NEW YORK.

Subscriptions to the Ogdensburg City Hospital annex already amount to $15,500.

The Craig Colony for epileptics now has 620 patients, and with the completion of the four new buildings now under construction, 120 more can be received.

Buffalo.

Dr. Matthew D. Mann has been elected park commissioner.

Dr. W. Scott Renner sailed for Europe March 6, to spend two months in Berlin and Vienna.

Dr. P. W. Van Peyma has been elected chairman of the board of school examiners for the year 1901.

The Emergency Hospital, which is supported by the Sisters of Charity, will soon remove into its new building.

Dr. John Farr, formerly of Buffalo, has been appointed an assistant surgeon in the army. Dr. Farr was for some time house surgeon at the Fitch Accident Hospital.

New York City.

The Post-Graduate Medical School and Hospital has received an anonymous gift of $15,000, to endow three beds in the children's ward.

The nurse in Bellevue Hospital who was charged with manslaughter, in having caused the death of one of the insane patients, has been acquitted.

Early in March, the first number of a scientific quarterly, under the title *New York University Bulletin of the Medical Sciences*, edited under the auspices of the New York University Medical Society, will be published.

Appointment.—The governor has appointed Dr. Daniel Lewis, former member of the State Board of Health, state health commissioner under the new law. He will have jurisdiction over the matters formerly coming under the notice of the state board. The salary is $3500 a year, and his term expires Dec. 31, 1904.

New Periodical.—The annual circular of the New York University is to be converted into a periodical, each number of which will contain, besides the circular matter, statements of recent progress in the university. This bulletin will be issued twice a month, except from August to December.

Smallpox.—New Cases of smallpox continue to be recorded. A public school teacher in Manhattan has just been reported with the disease, and two centers of smallpox have been unearthed by the health officials in Brooklyn. Eight cases were discovered in a row of tenements in Warren Street, and eleven smallpox patients were found in a four-story double apartment house in Driggs Avenue.

Hemophilia.—Elmer W. Roach, of Brooklyn, a student of dentistry, has died after three weeks of almost continuous bleeding from the nose and gums. This case of hemophilia is of special interest because Mr. Roach had reached the age of 22 years, and because about nine years ago he lost a leg in a railroad accident. If he had been a "bleeder" at that time he could not have survived the injury.

OHIO.

The estate of the late Dr. Alexander Neil, Columbus, valued at $150,000 is to be distributed equally among his three daughters.

Dr. John L. Boylan, Milford Center, fell from the roof of his barn, February 22, breaking two ribs and receiving other injuries.

Dr. Robert C. M. Lewis, Marion, formerly surgeon for the T. and O. C. R. R., has been appointed surgeon for the C., S. and H. R. R.

The vacancies on the medical staff of the National Military Home, occasioned by the resignations of Drs. Beal and Miller, have been filled by promoting Dr. Edward S. Breese to be first assistant surgeon; Dr. George H. Kress, second assistant; Frank W. Roush, third assistant, and A. L. Light, fourth assistant.

PENNSYLVANIA.

A conference has been held for the purpose of making a new annex to the Allegheny City Home for the Insane at Claremont. The new annex will cost about $120,000.

The pathologist to the Hospital for the Insane, at Norristown, will be compelled, hereafter, to examine the cattle at that institution in order to prevent tuberculosis, as certificates given by drovers are unreliable.

Drunkards Insane.—A resolution has been introduced in the house of representatives providing that persons of aggravated intemperate habits, be placed in an insane asylum until they are cured, and that they be recommitted in case of recurrence.

Philadelphia.

Dr. S. Weir Mitchell will leave for Vancouver, about March 15, and later go to Japan, returning in June.

Dr. Francis R. Packard has assumed the editorship of the *American Journal of the Medical Sciences*, to succeed Dr. Alfred Stengel, resigned.

The coroner's jury a few days ago recommended that the licenses of two women physicians be revoked, because they were conducting private maternity hospitals at their respective homes.

President Shoemaker, of the Pennsylvania Hospital, has appointed Messrs. John B. Garrett, and John Story Jenks, Dr. John B. Chapin, and Dr. Thomas G. Morton, a committee to make arrangements for the 150th anniversary of that hospital, to be held early in June.

GENERAL.

Honolulu's Board of Health has directed the attorney general to draft a bill, for presentation to the next legislature, prohibiting the landing of any persons suffering from any contagious and infectious disease. The bill is aimed especially at lepers and consumptives.

Congress of Nurses.—The International Congress of Nurses is to be held in Buffalo next September, for the purpose of strengthening the national and international organizations which the nurses of this country, Great Britain, the British colonies, Denmark, and Holland have been developing during the last few years. The nurses' national organizations in all these countries are pledged to work steadily for the advancement of educational standards and ethical development, and those of English-speaking countries also have in view the attainment of state examinations and registration. The organization in the United States is affiliated with the National Council of Women, and within the last year an international council of nurses has been organized, and will hereafter hold quinquennial meetings with those of the International Council of Women. The chairman of the congress is Miss Isabelle McIsaac, of the Illinois Training School for Nurses, Chicago, and the secretary, Miss Banfield, of the Polyclinic Hospital, Philadelphia.

California Plague Investigation Ended.

(Special Telegram from Our Own Correspondent.)

San Francisco, Cal., March 7 ,1901.—The Federal Commission, which, as recently noticed in The Journal columns, has been making an investigation of the plague conditions in San Francisco, has completed its work and its members left for the East on March 5. Inoculation experiments have been performed in all of the following cases and showed the positive presence of plague in every instance, these cases having occurred in San Francisco during the investigation of the Commission. In brief, these cases, which bring the number previously reported in The Journal to thirty-two, are as follows:

Case 26.—Chun Ah Chon, a male actor, 44 years old, born in China, died February 5, at the Chinese theater on Washington street.

Case 27.—Lum Hong Yuen, a male laborer, aged 37 years, born in China, died at his residence, 28 Ross alley, February 6.

Case 28.—Wong Chi Lin, a male, aged 50 years, a cigarmaker, born in China, and residing at 15 Waverly Place, died February 7.

Case 29.—Tom Shom, a male actor, aged 51 years, died at his residence, 814 Washington street, February 10. This case was under observation by the commission for three or four days before his death.

Case 30.—Ny Ah Bock, a male, 45 years old, died February 11, in St. Louis Alley. This case was attended by Dr. Mather, of San Francisco, and by him reported as suspicious. Glandular enlargement was found in the neck in this instance, and at the autopsy, which was performed by Prof. Simon Flexner, of the commission, the spleen was found very much enlarged, septic, the lymph glands of the neck much enlarged, hemorrhagic, and necrotic. Plague bacilli were found in enormous numbers in both the spleen and glands.

Case 31.—The details of this case are not yet completed.

Case 32.—Fong Lung Why, a male cook, 33 years old, was born in China. He died at his residence, 13 Waverly place. This man came from Sacramento about two weeks before death, and was sick when he arrived. There was no enlargement of the superficial lymph glands, but the spleen was much enlarged, septic, and contained enormous numbers of plague bacilli. The organism was obtained in pure culture from the spleen.

CANADA.

The Montreal Medical Society, consisting of French members, discussed and considered at the last meeting, the question of a new civic hospital for Montreal. The society favors a single hospital under the direct management of the city.

Dr. M. S. Frazer, of Brandon, Manitoba, one of the delegates to the tuberculosis conference recently held in Ottawa, and connected with the Indian department, as the medical superintendent of the Brandon Industrial School, will make a report on tuberculosis as it affects the Indians, so that the department may take any steps necessary to prevent this disease.

Ontario's Smallpox.—The situation in the province as regards the spread of smallpox is a trifle alarming. There are 3 cases in Toronto, all progressing favorably, and 83 in the province. In the County of Algoma there are 57; Carleton and Norfolk, 1 each; Middlesex, 2; York, Simcoe and Muskoka, each 3; Renfrew, 11; Haldimand, 1. The provincial board of health has organized a smallpox camp at Sudbury, where there are said to be 17 cases.

Sherbrooke Medical Society.—At the annual meeting held last week, Dr. J. F. J. Austin was elected president and Dr. J. O. Camirand, secretary-treasurer. The "lodge-doctor" was the principal topic of discussion and the Society decided to adhere to its previous decision, each member pledging himself to accept no position from any society as lodge physician. Another question was the relation of the doctors and druggists in the matter of counter prescribing, and it was decided to hold a conference in the near future, with the druggists of the city, to discuss the matter.

Injured in Chemical Laboratory.—An unfortunate accident occurred in the laboratory of Professor Ruttan, of McGill's faculty of medicine, recently, and will probably result in the partial blindness of a first-year medical student. The accident occurred through the unexpected explosion of a quantity of sulphuric acid and alcohol with which the students were experimenting. The test-tube of a neighboring student was submitted to Shaw's nose for his opinion as to the nature of the gas being given off, when it frothed up in his face, terribly burning it and also permanently injuring the right eye.

Indian Girls as Nurses.—The department of Indian affairs is considering the advisability of training girls at the industrial school at Brandon, Manitoba, in general nursing. This has been recommended by Dr. Fraser, who has the medical supervision of the institution. The value of having Indian female nurses in the Northwest can not be doubted, as the doctors are in many instances some distance from the Indian reserves, and it is also thought that the training of these girls would be in this way an education in the matter of preventing the spread of consumption amongst the Indians. Trained nurses will be brought to Brandon to train and instruct the female pupils in this work.

FOREIGN.

The hospital connected with the Tokyo University, Japan, according to mail advices just received, was burned January 29. Twenty-one patients were burned to death and ten patients and eleven nurses and attendants injured.

Smallpox in Dawson has abated, according to word from Port Townsend, Wash., bearing date of February 26. Public vaccinators are making a house-to-house visitation, accompanied by a squad of policemen.

The death of Prof. H. Schapiro, of St. Petersburg, is announced. He was the author of works on internal medicine. Prof. A. Rocha, editor of the *Coimbra Medica*, also died recently, and Mexico has lost a prominent member of the profession in the death of Prof. Alfonso Herrera.

Antituberculosis dispensaries are to be established in Paris, by a benevolent society. They are to be for the treatment of tuberculosis alone, and medicine, food and garments distributed gratuitously. The society will also supervise the patient at his home, to render the conditions as favorable as possible for recovery.

The Progress of the Plague.—On February 27, 7 new cases of plague were reported in Cape Town, South Africa, 2 being Europeans. The plague returns give 3396 deaths as the total for all India for the last week in January, with 3277 for the preceding week. In Bengal, where the greatest number of cases and deaths occurred, there were 2261 deaths, and in Bombay City 427 deaths during the last week in January, with 308 the previous week. In that city the epidemic increased markedly, with a report of 922 deaths for the second week in February. In Mauritius, the week ending February 14, 14 new cases of plague were reported with 10 deaths. In England, according to the *British Medical Journal*, the London County Council has authorized its Public Health Committee to spend £50,000 if necessary, in dealing with suspect and contact cases of plague. London has been divided into four districts for the purpose of isolation, and thorough accommodation for contacts and suspects will be provided in each district. Arrangements have been made for providing, in a few hours, for the accommodation of 200 persons at a time, at a cost of £16,000, and 600 more can be provided for within a few weeks should it be necessary. While these buildings are not to be commenced unless plague actually appears in London, £7000 is to be spent on the drainage, water-supply and preparation for the foundations for these temporary buildings.

Correspondence.

The Modern Methods of Quarantine.

St. Paul, Minn., Feb. 18, 1901.

To the Editor:—In the *N. Y. Medical Journal* of Nov. 3, 1900, Dr. A. H. Doty discusses this subject as bearing upon marine sanitation. It is true, as he states, that in the past there has been much unwarranted fussiness in the administration of marine quarantine. Methods have been in vogue that caused much delay in the discharge of passengers, mails and cargo, that were in no way based upon scientific teaching, and that were largely in demand chiefly for the benefit of the port sanitary officials.

Had Dr. Doty confined his arguments to marine sanitary methods deserving of criticism, his field would have been sufficiently wide. But there are many statements in his paper which have no bearing upon the disinfection of a cargo of iron in the hold of a vessel, or of rags that supposedly have been steamed and baled under pressure in a foreign country, or of passengers lined up on the deck, or of mails lying in an open boat. For example, the following statement appears: "Contrary to popular belief the most careful investigation, both from a scientific and a practical standpoint, has demonstrated that the clothing actually worn by well persons is not a medium of infection." There are few modern sanitarians who will accept this view. Few, I think, will admit that the well can not carry in their clothing the infection of scarlet fever or of smallpox directly deposited or transmitted through the atmosphere, from a patient in the stage of desquamation. Clothing soiled with the infectious discharge from a patient ill with typhoid fever, tuberculosis, or diphtheria can certainly convey infecton to others.

The following are a few illustrations of this fact: My father, a physician, was attending scarlet fever patients. He tried to prevent conveying the disease to his own family of small children, by carefully removing the suit worn while visiting such patients before returning to his home. In spite of these precautions, however, he undoubtedly did convey the disease to his own children, one of whom died in consequence.

A few years ago, while in attendance upon scarlet fever patients, I was careful so far as my clients were concerned, but somewhat careless in my methods as related to my return home, and my wife contracted the disease, beyond doubt through my carelessness. Dr. Montizambert, Director General of Public Health in Canada, in reporting on a recent outbreak of smallpox in Winnipeg (1900), says: "Careful and continual injury lead to the conclusion that he must have contracted the disease from the unpacking of infected clothing during his voyage from Hongkong." 'Quite recently infection of a family in Minnesota, with smallpox, was traceable to the visit of the father to one of his rented houses, in which there had been cases of smallpox a short time previously. His clothing must have conveyed the disease for he himself was not ill. Recently a woman whose child had died of diphtheria borrowed mourning goods of a neighbor. Diphtheria, soon after this borrowing, appeared in the family of the lender, undoubtedly due to infection, through the medium of the loaned clothing.

I mention these cases as a few that have come under my own observation. Dr. Doty admits that it is "within the bounds of possibility" for such cases to occur exceptionally. I venture to say that instead of being exceptions they are of daily occurrence, but unreported. The casual investigator will often fail to discover the source of infection in an outbreak of scarlet fever, smallpox or diphtheria, when the careful observer will find the fault to rest upon some healthy individual as the transmitter of the dissease. Dr. Doty further states: "The busy medical practitioner may during the day visit many cases of infectious disease and may go from them to others without previously changing his clothing or performing disinfection. He has reason to believe that he does not act as a medium of infection; as he sees no evidence of it in his own home, nor is evidence presented to him that he transmits disease to his patients." That the busy practitioner may do as thus stated is too true. Surgeons hesitate to go from a patient having an infectious disease to any operative work. Why should they hesitate if there is no danger of their conveying infection. I contend that every physician in attendance on certain infectious diseases, such as scarlet fever, smallpox, diphtheria, etc., should wear a protective gown, and this should be moist with an antiseptic solution at the time it is worn, or should be disinfected as soon as possible after such a visit. Dr. Doty, after expressing himself as to the absence of danger from the clothing of non-infected persons, says: "in municipal sanitary work this knowledge is valuable as we are then reasonably assured that the disease will not spread—at least to any serious extent—through the medium of clothing worn by well persons." Truly, this is a remarkable position to be taken by a sanitarian at this date. Were it true it would mean that the quarantine of the homes of those ill with smallpox and scarlet fever is unnecessary; that so long as the actual patient is kept at home no danger can follow the promiscuous mixing of other members of the family with the public at large. If his statement is true it means that the exclusion of healthy children, resident in an infected house, from school is a mistake. It may be true that there may be the attendance at school of many children from infected homes without the appearance of many cases of disease due to such exposure, but this does not prove the nonexistence of danger from such a course. One has but to study the rise in numbers of infectious diseases following the general opening of schools in the fall to realize that the association of children has much to do with the spread of infectious diseases, and that this increase in disease is dependent on the intermediate as well as the mediate infectious children. Dr. Doty, in support of his opinion, says: "As a matter of fact, many careful observers believe that the activity, at least of some, of the specific organisms is inhibited by an exposure of only a few minutes to air and sunlight." This proves nothing. Admitting some of his statements to be true, the argument does not apply to clothing, much of which gets little sunlight or air, even when in use.

It may be well to touch upon two other statements in Dr. Doty's paper: 1. "As far as I am able to ascertain no authentic report exists which shows that cargoes of vessels have transmitted bubonic plague through the medium of infected rats or other sources." This, it is not necessary for me to argue on further than to say that even should the statement be true, it does not prove that "rats or other sources" might not have transmitted the disease. He further states: "rats collected at New York from coffee-carrying vessels from Rio Janeiro and Santos, during the recent outbreak of plague in these two places were examined bacteriologically and in no instance was there the slightest evidence of bubonic plague." What, may I ask, does the Doctor expect to prove by this statement? To me it represents but a fortunate circumstance, for no one questions, I presume, that rats may be infected with the plague bacillus, nor would any one question the fact that had any of the rats on any of the ships examined been infected, a careful bacteriologic examination of such rats should have demonstrated the fact. 2. He also says: "Most careful investigation has failed to present satisfactory evidence that either foreign or domestic rags act as a medium of infection (for anthrax) although they include all kinds of wearing apparel, which is frequently filthy and offensive." Yet the Doctor must admit that anthrax has been brought into this country through infected media in ships' cargoes; and if capable of transmission in such media, why is it not possible that rags should be a means of transmission if infected?

I think any one who has traveled extensively by water can realize that there is much absurd maratime inspection, but that does not prove that infectious diseases can not be transmitted by cargo, passengers or clothing; or, in other words, that infected human beings are the only means of transmission for infectious diseases.

In conclusion, I can not agree with Dr. Doty either in the premises or conclusions presented in his article, and I think my position in this respect will be borne out by sanitarians and bacteriologists in general.

H. M. Bracken, M.D.

Fatality of the Rattlesnake.

Knoxville, Tenn., Feb. 26, 1901.

To the Editor:—Your editorial on the "Fatality of the Rattlesnake" induces me to say a word on the subject. The professor referred to therein is manifestly not posted on rattlesnakes. During the past eight years I have had occasion to spend a considerable portion of six winters in Southern Florida. The diamond rattler is a denizen of that region, and since I made my first visit there eight years ago, I know of three men, a horse, and a number of dogs dying from rattlesnake bites. The diamond rattler is said to be the most poisonous of all, and attains an enormous size; fortunately he is usually peacibly inclined, and all he asks is to be let alone.

On one of my visits there I talked with an Indian on the subject, and asked him how he cured rattlesnake bites. He very promptly answered: "Don't cure him. Big sleep. Big sleep." So, not only the Indians of that section, but the whites also consider a man as good as dead when a diamond rattler strikes him.

C. Deaderick, M.D.

Association News.

New Members.

The following is a list of new members of the A. M. A. for February, 1901:

ALABAMA.

Kilflebrew, J. Buckner, Mobile.

ARKANSAS.

Christian, R. B., Little Rock.

CALIFORNIA.

Barbat, Wm. F., San Francisco.

CONNECTICUT.

Bell, Newton S., Windsor.

FLORIDA.

Pierce, Claude C., Key West.

ILLINOIS.

Lockhart, Charles H., Witt.
Davis, John A., Farmer City.
Scott, R. G., Geneva.
Bench, Edward M., Galena.
Fisher, Frank B., Springfield.
Plummer, Amzi S., Peoria.
Bishop, Arthur M., Chicago.
Giles, Henry Wiley, Wataga.
Ballard, C. N., Chicago.
Lyons, John A., Chicago.
Montgomery, Frank H., Chicago.

INDIAN TERRITORY.

Donohue, Philip, Afton.

INDIANA.

O'Day, John C., Montpelier.
Allen, Horace R., Indianapolis.

IOWA.

Neill, Hiram, Sibley.
Ratcliffe, J. J., Waukon.
Struble, Andrew, Inwood.
Evans, M. M., Le Grand.

KENTUCKY.

Schultz, Wm. F., Covington.
Dickinson, Jos. S., Trenton.
Forsythe, M. L., Harrodsburg.
Meredith, T. O., Burgin.

LOUISIANA.

Powlett, Stephen L., Hammond.

MARYLAND.

Morrison, Wm. Baker, Hagerstown.
Pitsnogle, J. E., Hagerstown.
Penrose, Clement A., Baltimore.

MASSACHUSETTS.

Pierce, A. Martin, New Bedford.
Miller, Jarred H., Wollaston.
Crowell, Samuel, *Boston*.

MICHIGAN.

Burnham, Wm. A., Hancock.
Gammon, H. B., Hastings.
Campbell, Alexander Mackenzie, Grand Rapids.
Long, C. M., Escanaba.

MINNESOTA.

Palmer, Walter A., Redwood Falls.
Hirschfield, Adolph, Minneapolis.
Nippert
De Jon
Cutts,
Hunt,
Murphy, Wm. B., Minneapolis.

MISSOURI.

Witherspoon, T. C., St. Louis.
Ketcham, C. M., Carthage.
Robinson, G. W., Joplin.
Wallace, Charles H., St. Joseph.
Burke, Foster W., Laclede.

MISSISSIPPI.

Bridges, Robert Richard, Bridgeville.
Ward, B. F., Winona.

NEBRASKA.

Fochtman, John H., Cozad.

NEW HAMPSHIRE.

Wheat, A. F., Manchester.

NEW JERSEY.

Weeks, David F., Trenton.
Bennett, J. K., Gloucester City.

NEW YORK.

Bemis, Morris N., Jamestown.
Douglas, W. E., Middletown.
Evans, Wm., Westtown.
Myers, Frank D., Slate Hill.
McPhail, Donald T., Purdy Station.
Smith, Harrie Eugene, Mt. Vernon.
Bullard, W. Duff, New York City.
Manning, F. O., New York City.
Hubbell, Marvin D., New York City.
Neuhaus, G. E., New York City.
Farrington, Jos. Oakley, New York City.
Herter, Christian A., New York City.
Ferguson, James A., New York City.

NORTH DAKOTA.

Hood, Charles E., Drayton.

OHIO.

Koehler, James A., Shelby.

PENNSYLVANIA.

Tappan, L. N., Philadelphia.
Deaver, Richard W., Philadel*phia*.

Culpepper, Vernon G., Portsmouth.
McGuire, Stuart, Richmond.

WISCONSIN.

Winslow, Rush, Appleton.
Noyes, Geo. Kasson, Milwaukee.
Gilberson, Peter C., Mt. Horeb.

St. Paul as a Place of Meeting.

Many of the members of the American Medical Association remember with pleasure their last meeting in St. Paul. It was June, 1882, nearly twenty years ago, the month being one of the most beautiful in the year in Minnesota. Some of the members have passed away since then, and younger men have taken their places, but those still living, who were in St. Paul then, speak with enthusiasm of the saintly city, its beauty, pleasant environments and the cordial hospitality that made the meeting of 1882 so memorable a one. This year the Association will find many changes, and the physicians and their wives who were there then and who have not visited St. Paul in the interim will have some difficulty in recognizing it. For in nineteen years St. Paul has grown from a town to a city; a city of broad asphalted streets, with electric cars running in every direction, fine public buildings, good hotels, beautiful churches, theaters, pretty parks in the city, and Como Park outside. There are four well-equipped hospitals, which the citizens justly claim are not equalled in any city of the size in the country. Then there is picturesque, historic Fort Snelling, only a few minutes drive or street-car ride from the city; Hamline University, the St. Paul Seminary and the Agricultural College, all institutions in near suburbs and all worth a visit by the tourist. Minneapolis, which contains much of interest, is connected with St. Paul by two electric lines. St. Paul, situated as it is on the high ground on the left bank of the Mississippi, has so many natural advantages that it has not been difficult to make it one of the most beautiful cities of the West. The old union depot has been enlarged as the city has grown, and near it runs a car line from which the strangers can transfer to all the other lines running through town and out into the suburbs. The electric-car system in the twin cities is in every way abreast of the times. The Association is fortunate in the time of the meeting, June, as Minnesota weather is then "showing off." The city will be looking its prettiest, as it is just after the "spring cleaning," and before the hot sun of midsummer has had a chance to blister the fresh green leaves. The season is also just beginning at near-by lakes, of which there are so many. The sunny skies of Minnesota have been compared to those of Italy, and the combination of cool air and the warm June sun make this particular season of the year the most desirable one for out-of-town visitors.

Married.

Horatio B. Withers, M.D., to Miss Mary L. Wester, both of Mineral Wells, Texas, February 12.

Harry P. Findley, M.D., Massillon, Ohio, to Miss May Quinby, of Monmouth, Ill., February 14.

Daniel G. R. LeQuesne, M.D., Cleveland, Ohio, to Mrs. Mary R. French, of The Dalles, Ore., at Toledo, Ohio, February 25.

Deaths and Obituaries.

Abbott Hodgman, M.D., New York University, 1858, died at his home in New York City, February 27, aged 68 years. He served on the staff of Blackwell's Island Hospital, N. Y., having medical charge of the local prison for eight years. In 1884 he was a member of the commission appointed to investigate tenement conditions. He was a member of the American Medical Association and a trustee of both the Metropolitan Museum of Art and the New York Savings Bank.

Samuel Camp, M.D., New York University, 1851, of Great Barrington, Mass., died February 29, aged 72. He began practice in New Marlborough, Mass., and four years later went to Michigan, returning to Great Barrington in 1859. He was surgeon of the Twenty-seventh Massachusetts infantry during the Civil War.

Seneca T. Hyde, M.D., University of Vermont, Burlington, 1866, a successful practitioner of Neponset, and a member of the Norfolk District and Massachusetts Medical Societies, died at Hamilton, Bermuda, where he had gone for his health, February 17, aged 65.

John H. Renner, M.D., Northwestern University Medical School, Chicago, 1864, died at his home in Lagro, Ind., from Bright's disease, February 21, aged 70. He was a member of the American Medical Association.

William B. Thomason, M.D., University of Georgia, Augusta, 1854, who had practiced in Bullock County for nearly half a century, died at his home in Louisville, Ala., February 2, aged 74.

Thomas O'Reilly, M.D., Royal College of Surgeons, England, 1849, died February 24, at his home in St. Louis, Mo., where he had practiced for more than fifty years, aged 74. He was a member of the British Medical Association.

William F. Aiken, M.D., Harvard Medical School of Boston, 1886, killed his wife and himself February 27, at his residence in Savannah, Ga. He was 35 years of age and had been mentally unbalanced for several years.

Matthew C. Martin, M.D., Milwaukee Medical College, 1899, died at the Milwaukee County Hospital, of which he was assistant resident physician, February 21, from typhoid fever, aged 25.

William Glenn, M.D., University of Minnesota, 1893, and professor of physical diagnosis at Hamline University, died from pneumonia, at his home in Minneapolis, February 20, aged 41.

Dewees Cunningham, M.D., Medical College of Ohio, Cincinnati, 1871, an esteemed practitioner of Wurtemburg, Pa., died from heart disease at his home in that place, February 19, aged 59.

William F. Frost, M.D., Rush Medical College, Chicago, 1896, died at the residence of Dr. Harry R. Desmond, Plattsburg, Mo., February 18, from pulmonary tuberculosis, aged 27.

Edwin A. Fessenden, M.D., Bellevue Hospital Medical College, New York, 1889, died on February 28, at Portland, Me., from poisoning by carbolic acid accidentally taken, aged 55.

Horatio N. Bradshaw, M.D., Rush Medical College, Chicago, 1867, died at his home in Superior, Neb., February 22, after an illness of three weeks.

Street Jones, M.D., Bellevue Hospital Medical College, New York, died from pneumonia, at his home in Goldsboro, N. C., February 20, aged 27.

Littleton F. Brittingham, M.D., Missouri Medical College, St. Louis, 1847, died suddenly at his home, Hannibal, Mo., February 24, aged 80.

Warden James Byers, M.D., College of Physicians and Surgeons, New York, 1889, died at his home in Brooklyn, N. Y., February 22, aged 38.

John W. Elliott, M.D., University of Louisville, Ky., 1883, of Lake City, Miss., died after a long illness at Yazoo City, Miss., February 14.

B. F. Longstreet, M.D., Jefferson Medical College, died at his home, Mount Auburn, Cincinnati, Ohio, February 21, from la grippe, aged 52.

Stephen J. Clark, M.D., University of New York, 1861, for many years a practitioner in New York City, died in Sing Sing, N. Y., February 24.

J. J. Bozeman, M.D., Medical College of the State of South Carolina, Charleston, 1857, died at his home in Ninety-Six, S.C., February 19.

E. F. Tidwell, M.D., Louisville Medical College, 1882, a practitioner of Lester, Ark., was found dead at Camden, Ark., February 25.

Samuel B. Park, M.D., Beaumont Hospital Medical College, St. Louis, 1888, died at his home in Winfield, Kan., February 14, aged 56.

Charles E. V. Gissy, M.D., Washington University, St. Louis, 1875, died at his home in Breese, Ill., February 21, aged 47.

Charles S. Hinman, M.D., Dartmouth Medical College, Hanover, N. H., 1875, died at his home in West Charleston, Vt., aged 54.

Miscellany.

Yellow Fever Investigation.—We give below the abstract of the interim report published by H. E. Durham and the late Walter Myers, of the Liverpool School of Tropical Medicine's yellow fever investigation, in the *British Medical Journal* of February 23. The complete report was interrupted by the authors being attacked by yellow fever, and, as previously noticed in The Journal, the results to Dr. Myers were fatal. This abstract was published before its authors could have known of the results reported by Reed, Agramonte and Carroll, in The Journal of February 16. The authors' conclusions are as follows:

1. Sufficient search reveals the presence of a fine small bacillus in the organs of all fatal cases of yellow fever. We have found it in each of the fourteen cadavers examined for the purpose. In diameter the bacillus somewhat recalls that of the influenza bacillus; seen in the tissues it is about 4 microns in length. 2. This bacillus has been found in kidney, in spleen, in mesenteric, portal and axillary lymphatic glands, etc., taken from yellow fever cadavers directly after death. In the contents of the lower intestine apparently the same bacillus is found often in extraordinary preponderance over other microorganisms. Preparations of the pieces of "mucus," which are usually, if not always, present in yellow fever stools, at times may almost present the appearance of "pure culture." 3. Preparations of the organs usually fail to show the presence of any other bacteria, whose absence is confirmed by the usual sterility of cultivation experiments. 4. It is probable that

this same bacillus has been met with but not recognized by three other observers. Dr. Sternberg has mentioned it; and he has also recorded the finding of similar organisms in material derived from Drs. Domingos Freire and Carmona y Valle; but he did not recognize its presence frequently, probably on account of the employment of insufficiently stringent staining technique. 5. It is probable that recognition has not been previously accorded to this bacillus by reason of the difficulty with which it takes up stains (especially methylene blue), and by reason of the difficulty of establishing growths on artificial media. 6. The most successful staining reagent is carbolic fuchsin solution (Ziehl), diluted with 5 per cent. phenol solution (to prevent accidental contamination during the long staining period), immersion for several hours, followed by differentiation in weak acetic acid. Two hours staining period may fail to reveal bacilli, which appear after 12 to 18 hours. The bacilli in the stools are often of greater length than those in the tissues, and they may stain rather more easily; naturally the same is true of cultures. 7. Since the bacilli are small and comparatively few in numbers they are difficult to find. To facilitate matters at our last two necropsies (14th and 15th) a method of sedimentation has been adopted. A considerable quantity of organ juice is emulsified with antiseptic solutions, minute precautions against contamination and for control being taken; the emulsion is shaken from time to time and allowed to settle. The method is successful and may form a ready means of preserving bacteria-containing material for future study. The best fluid for the purpose has yet to be worked out; hitherto normal saline with about one-fifth per cent. sublimate has been employed. 8. Pure growths of these bacilli are not obtained in ordinary aërobic and anaërobic culture tubes. 9. Some pure cultures have been obtained by placing whole mesenteric glands (cut out by means of the thermo-cautery) into broth under strict hydrogen atmosphere. Investigations into the necessary constitution of culture media for successful cultivation are in progress. 10. Much search was made for parasites of the nature of protozoa. We conclude that yellow fever is not due to this class of parasite. Our examinations were made on very fresh organ juices, blood, etc., taken at various stages of the disease, with and without centrifugalization, and on specimens fixed and stained in appropriate ways. We may add that we have sometimes examined the organs in a fresh state under the microscope within half an hour after death. 11. The endeavor to prove a man-to-man transference of yellow fever by means of a particular kind of gnat by the recent American Commission is hardly intelligible for bacillary disease. Moreover, it does not seem to be borne out by their experiments, nor does it appear to satisfy certain endemiological conditions. It is proposed to deal more fully with the endemiology and epidemiology of the disease on a later occasion. 12. We think that the evidence in favor of the etiological importance of the fine small bacillus is stronger than any that has yet been adduced for any other pretended "yellow fever germ." At the same time there is a much further work to be done ere its final establishment can be claimed. The acquisition of a new intestinal bacterium would explain the immunity of the "acclimatized."

Extra-respiratory Cough.—A. Martiner devotes an article, in the *Presse Médicale* of January 23, to the reflex coughs which occur without symptoms in the respiratory passages. The aim of treatment should be: 1, to diminish the sensibility of the mucous or serous membrane starting the reflex; 2, to diminish the excitability of the nerve center presiding over the cough; 3, to act on the centrifugal routes, and 4, to induce the will to control the bulbar center. The first of these indications includes the removal of the cause and, sometimes, anesthetizing the mucosa. Frequently the cough is arrested instantaneously by cocainizing the nasal fossæ or drinking a chloroform-cocain potion. Opium and its derivatives answer the second indication in ordinary coughs, but are injurious in this so-called reflex cough. The bromids are useful and also Meglin's pills—5 cg. each of extract of hyoscyamus, extract of valerian and zinc oxid, for one pill—to be taken three times a day. The centrifugal routes are sometimes brought under control by applying two Milan plasters over the phrenic nerve, one in the cervical region above the clavicle, between the two heads of the sterno-cleido-mastoid muscle; the other at the lower edge of the ribs, over the "phrenic button." This measure has proved particularly useful in reflex coughs accompanied by hyperesthesia along the course of the phrenic nerve. The will-power should be strengthened by suggestion.

Societies.

COMING MEETINGS.

Medical Society of the Missouri Valley, Omaha, Neb., March 21, 1901.

Tri-State Medical Society of Iowa, Illinois and Missouri, Keokuk, Ia., April 2-3, 1901.

Medical Association of the District of Columbia, Washington, D. C., April 2, 1901.

Tennessee State Medical Society, Nashville, April 9-11, 1901.

Florida Medical Association, Jacksonville, April 10, 1901.

Western Ophthalmological and Otolaryngological Association, Cincinnati, Ohio, April 11-12, 1901.

Medical Association of the State of Alabama, Selma, April 16, 1901.

Medical Society of the State of California, Sacramento, April 16-18, 1901.

South Carolina Medical Association, Florence, April 17, 1901.

Medical Association of Georgia, Augusta, April 17, 1901.

Louisiana State Medical Society, New Orleans, April 18-20, 1901.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 23-26, 1901.

Texas State Medical Association, Galveston, April 23, 1901.

American Association of Genito-Urinary Surgeons, Old Point Comfort, April 30, 1901.

Association of American Physicians, Washington, D. C., April 30, 1901.

Italian Congress of Pediatry.—The general secretary of this Congress, which will convene for its fourth session at Florence, October 15, is Dr. Luigi Concetti of Naples.

German Congress of Surgery.—The date appointed for the thirtieth session of the Congress is April 10 to 13, and the place, Berlin. Professor Czerny, of Heidelberg, has the arrangements in charge.

German Congress of Dermatology.—The seventh session of the Congress opens at Breslau, May 28, with addresses by Finsen, Schiff, Freund and others. Professor Neisser of Breslau is to preside.

Southwestern Iowa Medical Association.—The seventh annual convention of this Association was held in Creston, February 21. Dr. Vernon L. Traynor, Council Bluffs, was elected president; Dr. Donald Macrae, Council Bluffs, vice-president; Dr. Frank E. Sampson, Creston, secretary, and Dr. Joseph P. Claybaugh, Creston, treasurer.

Columbus (Ohio) Academy of Medicine.—The annual meeting and banquet of the Academy was held February 26, President Dr. James C. Lawrence in the chair, and Dr. Theodore W. Rankin officiating as toastmaster. Dr. Dudley P. Allen, Cleveland, was the guest of honor, and responded to the toast: "The Profession in the Metropolis of Ohio."

Oneida County (N. Y.) Medical Association.—The members of the First District Branch of the New York State Medical Association, residing in Oneida County, met at Utica, February 25, and organized the Oneida County Medical Association, with the following officers: Dr. William B. Reid, Rome, president; Dr. Henry C. Palmer, Utica, vice-president; Dr. J. O. Stranahan, Rome, secretary, and Dr. John Groman, Utica, treasurer.

New York State Medical Association.—A special meeting of the members of the First District Branch was held in Utica, February 25, for the purpose of reorganizing the branch association. The meeting was opened by an address of welcome by the president, Dr. Charles B. Tefft, Utica, after which the following officers were elected: Dr. J. Wallace Douglas, vice-president, Boonville; and Dr. Edgar H. Douglas, Little Falls, secretary and treasurer.

Sullivan County (N. Y.) Medical Association.—The members of the Fifth District Branch of the New York State Medical Association, residing in Sullivan County, met at Liberty, February 19, for the purpose of organizing the Sullivan County Medical Association. The following officers were elected: Dr. Charles S. Payne, Liberty, president; Drs. Frank P. Howser, Centreville Station, and Stephen W. Wells, Liberty, vice-presidents; Dr. John L. C. Whitcomb, Liberty, secretary, and Dr. Charles W. Piper, Wurtsboro, treasurer.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Meeting held February 25.

President Dr. James Tyson in the chair.

Astereognosis.

Drs. W. H. Teller and F. X. Dercum exhibited a case of this affection. The patient was a man 30 years of age, who was, on Nov. 17, 1900, struck on the head by a base-ball bat, and was admitted to the Jewish Hospital six days later, unconscious. A small cut was present over one eyebrow, and there was a depression in the region of the fissure of Rolando. There was complete paralysis of the right arm and leg, and deviation of the right eyeball. An incision was made over the depression and the bone removed. The membranes of the brain were congested but intact. A cot extending for two inches down into the brain substance was removed, and on removal a small amount of brain substance discharged. The patient, who had been unconscious for six days, several hours after the clot was removed regained consciousness and, on the following day, the paralysis of the right arm and leg began to disappear.

Six weeks later Dr. Dercum found astereognosis present. At this time the man was totally unable to recognize anything placed in the right hand, such as a spoon, scissors, or other object, but these could be at once determined by the left hand. Tactile sensation was partly preserved on the right side. Hypesthesia was marked in the region of the extremities. When the eyes were shut with the right hand, the man was unable to tell the position in which the fingers were placed. There was some defect of the muscle sense. When he would stand and close the eyes he would sway considerably. There was more or less ataxia of the right arm. When he closed his eyes he was unable to touch the tip of the nose without considerable trouble. It was evident that he had a lesion of the parietal lobule involving the parietal convolution, giving rise to the astereognosis.

Drs. George L. Walton and Walter E. Paul, of Boston, by invitation, read a paper entitled "Astereognosis with Illustrative Cases." Dr. Walton stated that the literature on this subject had been considerably added to by Dana, Burr, Sailer, Mills, Keen and other writers. As to the differentiation between hysteria and an organic lesion in which astereognosis is present, if hysteria, this symptom will disappear suddenly. It appears that the muscle nerve fibers follow a different course from those of the cutaneous sensation. The ability to close the eyes, and to recognize objects depend on contact sense and muscle sense. The first case reported was one who had occipital headache, involuntary movement of the eye, and ankle-clonus. This patient was unable to recognize objects with the left hand. The temperature and pain sense were lost. The patient gradually became worse and an operation was done by Dr. Warren. The surface of the brain presented no abnormality. A cyst was, however, detected lower down. Six weeks later the paralysis gradually disappeared, but death subsequently occurred.

The second case had been seen on Dec. 7, 1900, the patient stating that for some time there had been numbness of the left hand and later numbness of the left leg. Slight aphasia was also present. When seen she was unable to recognize an object such as a bottle, but could recognize a key. A short time later double optic neuritis appeared. In this case an operation was done and a growth, the nature of which was doubtful, removed. No change in the paralysis occurred, except that the aphasia became more marked as well as mind blindness.

In a third case the paralysis was limited to the lower extremities. The patient could distinguish a pencil if applied transversely over the foot. In this case there was a history of paralysis of the left leg, and attacks of Jacksonian epilepsy occurring in one toe on the left side. Double optic neuritis was present. The Babinsky reflex was present. Pain and temperature sense were normal. In this case an opening was made in the skull in the region of the fissure of Rolando, and just behind the fissure the remains of an old clot found. The next day the motor paralysis extended to the hand. Articles placed in the hand could not be recognized. Convulsions occurred a few weeks later, but subsequently she regained a moderately good condition. The speaker does not believe that experiments on the lower animals would be of a very great value in the determination of the exact nature of astereognosis. In over fifty old cases of hemiplegics astereognosis was not present in thirty of them.

Dr. F. X. Dercum, in discussing this paper, expressed belief that we have to deal with both a motor and a sensory astereognosis.

Dr. Charles W. Burr thought the term "astereognosis sense" not altogether a good one; "asterognosis faculty" seems preferable. He once saw a man who had suffered from a fracture of the skull, from which he had recovered. When seen by the speaker there was no disturbance of sensation. He knew the position of pain, of heat and of cold, but with his eyes closed could not recognize a single object. He also knew of a case of mind blindness in which heat and cold were recognized. In his opinion there is some center in the brain which stores up things which have been felt, and this center might be in the posterior parietal lobule.

Dr. J. Hendrie Lloyd stated that he at one time treated a case in which the patient could not tell the term to apply to an object placed before her, such as a knife, key or handkerchief, but when these were placed in her hand they could at once be recognized.

Dr. Wm. G. Spiller spoke of different writers who had made investigations on this subject. He referred to the different tracts in the cord, such as that conveying tactile sense, some writers believing this to be in the lateral columns while others place it in the posterior.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Meeting held February 18.

Parker Syms, M.D., *President.*

Ulcer of Placenta; Umbilical Cord Severed Before Birth.

Dr. Eden V. Delphey presented this specimen. The patient, a multipara, aged 32, while hanging up clothes suddenly experienced a tumultuous sensation in her abdomen, and this immediately followed by the onset of labor, though she had been pregnant only 7½ months. That evening, or about twelve hours later, Dr. Delphey performed manual dilatation, and with the aid of forceps delivered a dead fetus. It was found that there was only a short stump of umbilical cord attached to the child at its birth, though the total length of the cord was fourteen inches. Examination of the placenta after its spontaneous delivery revealed the presence of an ulcer, one inch in diameter, and this the pathologist reported to correspond to a broken down gumma. Two hours after the birth of the child the mother developed symptoms of internal hemorrhage and severe collapse, and died.

Lack of Uniformity in Prescribing Myopic Glasses.

Dr. S. Busby Allen read a paper on this subject. He said that carelessness in prescribing eyeglasses for myopes leads to much distress on the part of the patient, and if not relieved the ultimate effect may be morbid introspection and even mental deterioration. There is considerable difference of opinion concerning the effect of accommodation.

Dr. Henry Oppenheimer pointed out that by proper attention to the habits of life of many children much can be done toward preventing the development of a high degree of myopia. Such children should be encouraged to participate in out-door games, and should be prevented from reading in a poor light, or in faulty positions which tend to produce congestion of the vessels of the head. It is most important to correct, as far as possible, the effort at convergence.

Dr. Frank Skeel said that the apparent lack of uniformity in prescribing glasses for myopia is explained by the necessity for treating each case by itself. For low degrees of myopia, it is his custom to prescribe glasses which fully correct the error; for high degrees of myopia, very little can be done. When the myopia is found to be increasing, marked benefit will often accrue from keeping the eyes under the influence of atropin for six weeks or more.

Dr. J. H. Woodward agreed with what had been said about the great importance of correcting very early in life the slight degrees of myopia. Where it is moderate in degree, glasses for distance should be worn, also for reading, in order to strengthen the muscles of accommodation. There would be less myopia among our school children if they were not so overworked in school.

Dr. J. Herbert Claiborne said that it had been his practice for many years to endeavor in youth to give the myope as nearly as possible perfect distant vision, the glasses being worn for both near and distant work. By a process of education the muscles of accommodation can be readily accustomed to this change.

A New Operative Method of Exposing the Seminal Vesicles and the Prostate for the Purpose of Extirpation or Drainage.

Dr. Eugene Fuller read a preliminary report on this subject. It will appear in The Journal.

A Contribution to the Bottini Operation for the Radical Relief of Prostatic Obstruction.

Dr. L. Bolton Bangs, author of a paper on this topic, expressed the opinion that enlargement of the prostate usually begins in early life. Although he has had an experience of three years with the Bottini operation, he looks upon it as a serious one, for which the patient should be most carefully prepared. The operation requires skill, and should be done very slowly, as this slowness is the best guarantee against secondary hemorrhage. The operation is apt to be followed by frequent and scalding urination, and with bloody urine for twenty-four or forty-eight hours. In from one to three weeks there is very often secondary hemorrhage. From the tenth to the fourteenth day dark particles of burned tissue make their appearance in the urine; occasionally there will be larger fragments. In 11 out of his 35 cases there was fever, and 6 had distinct chills within twelve hours after the operation. The patient should not be allowed up for one week, and should not resume his occupation for about two weeks more; in any case, he should be kept under careful observation until the urine becomes clear and there is no longer irritation. It is important that during the operation the electric current be kept up sufficiently to preserve the blade of the instrument constantly at a white heat. In one of his cases it failed in the midst of the operation, and he was compelled to complete the work with a Paquelin cautery. The result was instructive, for the Paquelin cautery had produced a thick, leathery eschar, but no action in the adjacent tissues, while the galvanocautery had produced a peculiar change in these tissues, which could be readily appreciated by the surgeon, yet the eschar was fine and thin. In 20 per cent. of his cases an increased amount of spontaneous urination resulted, while 20 per cent. were not improved. The greatest benefit was noted in those who had been largely or completely dependent on the catheter. One death was attributable to the operation, having been caused by sepsis, and as two others had occurred within two weeks, they were mentioned, though he does not feel at all sure that the operation was either directly or indirectly, responsible for them.

Dr. Willy Meyer said that he had done this operation on thirty-nine patients. He called attention to the fact that gonorrhea was a factor in about 75 per cent. Local anesthesia is ordinarily not advisable, but if employed better results will follow from mixing two-thirds of an ounce of a 2 per cent. solution of cocain with one ounce of a 3 per cent. solution of eucain. Where the kidneys had been normal he used either general or spinal anesthesia. The latter acted very well in the five cases in which it was tried. As he believes the depth of the incision in the Bottini operation is of importance, he is in the habit of repeating the posterior incision at the time of operaton. The pain after the operation is often intense, and for this reason he has adopted the plan of tying in a smooth Mercier catheter. In this way, much relief is afforded, and if the precaution to keep the urine loaded with antiseptics is taken, the effect of such a practice is to set up a sort of continuous antiseptic irrigation. He is confident that it is a valuable procedure, though not in accordance with established practice at the present time. The after-treatment is certainly arduous and most important in a case operated on by Bottini's method. He thinks that prostatectomy will come to be the operation for "hard" prostates and those having a hard nucleus.

Dr. Eugene Fuller said that he had long been an earnest advocate of prostatectomy, and the results from Bottini's method certainly do not make him feel like abandoning the method he has so long championed and practised. He is of the opinion that the Bottini method will result in relapses from the formation of the cicatricial tissue—indeed, his chief objection to that method is in the fact that one must burn through the tissues of the bladder to reach the prostate. Another serious objection is that it provides no means of securing for the bladder the surgical rest which, in its diseased state, is so often imperatively demanded.

Dr. J. W. S. Gouley said that the selection of the operation should be founded on an exact diagnosis. It should be remembered that Mercier failed in his prostatotomies and prostatectomies where there had been any considerable enlargement of the supramontanal folds. He believes that the Bottini operation is contraindicated in those cases in which the third lobe projects 2 or 3 cm. into the bladder. He himself introduced Mercier's operation into this country, and has performed it upwards of fifteen times. Where the prostate is very large, irrespective of whether it is soft or hard, prostatectomy is the operation to be selected, and he believes its dangers have been much exaggerated. He has dissected about one thousand prostates, and as an outcome of this experience is in a position to assert that the really hard prostate is of rare occurrence.

Dr. S. Alexander paid a tribute to Dr. Bangs for his very fair and judicial presentation of his experience with the Bottini operation, and pointed out that this paper has placed the profession in possession of certain new facts. The author has shown that the operation is not always successful, that the period of convalescence is longer than we have been led to suppose, and that he can not claim that a permanent groove remains in the prostate, for he has seen contraction of fibrous tissues as a result of a burn. Through the courtesy of Dr. Bangs, he was allowed to examine a prostate taken, at autopsy, from a man who subsequently died from an entirely independent cause. That specimen showed scars, the result of contraction, but no grooves. When a prostatectomy is done, the whole prostate is not taken out, but only those portions causing the obstruction. He does not deny that his operation of prostatectomy is associated with a high rate of mortality and is a very difficult one, but he contends that it is founded on a correct principle, and that the bad results are purely the outcome of a defective technique and of our general ignorance of the subject. He believes the Bottini operation a valuable form of prostatotomy for certain cases. It should be constantly borne in mind that the principal cause of obstruction is not intravesical.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, January 22.

Arsenious Acid in Malignant Growths.

Dr. H. M. Sherman occupied the chair, in the temporary absence of the president, Dr. D. W. Montgomery.

Dr. Howard Morrow read a paper by Dr. Montgomery and himself, entitled "Arsenious Acid in the Treatment of Cancer of the Nose and Face," and presented several cases. The paper consisted of the histories of some patients so treated, and described the technique and the indications for its application. In the clinic they had long talked of the advisability of taking up this mode of treatment, especially since the publication of the articles by Dr. A. R. Robinson, of New York, in favor of it. The histories of the patients shown ran as follows:

Mrs. R., aged 67, entered the clinic on Aug. 27, 1900, showing an epithelioma on the right temple, one-half an inch behind the right eye-brow; it was of about the size of a five-cent piece, and not ulcerated. The paste was applied for two days in succession; it healed kindly in three weeks, and the remaining scar is hardly perceptible.

F. M., aged 60, entered the clinic on Aug. 28, 1900, with an epithelioma of the right cheek, just below the outer canthus, which he said had lasted for ten years. The epithelioma was the size of a dime, ulcerated in the center, and surrounded by a typical waxy border with dilated capillaries crossing over it.

He supposed it to have started from the burn of a sulphur match. The paste was applied three times, for twenty-four hours each time; the resulting sore healed in four weeks, and the scar is very small.

T. B., aged 73, entered the clinic July 6, 1900, for an epithelioma of the nose, which he said had lasted for five years. The lesion was slightly larger than a split bean, was ulcerated in the center, and was surrounded by a hard, raised border, covered with dilated capillaries. There were two applications of the paste, of twenty-four hours each; the resulting sore healed uneventfully in four weeks, the scar being hardly noticeable.

C. F. S. entered the clinic on Aug. 27, 1900, suffering from a rodent ulcer on the right side on the upper lip, over one-half inch in diameter; it had an ulcerated center, and the border was hard, waxy, and infiltrated. There was a great amount of infiltration throughout the right half of the lip. The paste was applied four times for twenty-four hours each time, and the infiltration entirely disappeared, the lesion healing in five weeks, leaving nothing at present but a hypertrophied cicatrix. This was the most difficult case of all to treat, as the position was awkward and the infiltration deep.

Two other patients had been treated and discharged as cured, but the authors had been unable to trace them. They thought that all cancers situated at mucocutaneous junctions, or on mucous surface, in which there is apt to be early involvement of the lymphatic nodules, are best treated by the excision of the growth itself, and adjacent lymphatic channels and nodules; but that the small-celled variety, commonly known as superficial epitheliomas, or rodent ulcers, and usually situated upon some part of the face, are best treated by methods other than operative. The most effective of the non-operative methods are the actual cautery and the various caustics. The caustics commonly employed are chlorid of zinc, chromic acid, caustic potash, formalin, and arsenic. Other methods have been used, such as injections of silver, arsenic, alcohol, aniline dyes, toxins, and electrolysis, but the results have not been satisfactory. Treatment by the *x*-ray is uncertain, many cases not healing at all, and in all it is very slow. Liquid air has been used experimentally in a few instances; it is more painful than caustics and no better in its results.

The patients presented had been treated by arsenic. The strength of the arsenical paste has considerable to do with the result. Marsden never used arsenic stronger than two parts of the arsenious acid to one of the diluent, nor weaker than equal parts of the arsenic and diluent.

In a great many of the recipes given by writers the arsenic is used in smaller quantities; in many, in ridiculously small. The paste used by the authors contained 5 parts of arsenious acid, 3 of gum arabic, and 2 parts of cocain. Just before applying, this powder was mixed with enough water to make a thick paste; the amount of water used is of importance, for if not enough is added to the powder the paste will ball, and not apply well, and if too much is added the paste will run. It will be observed that this paste is only as strong as the weakest recommended by Marsden.

The area to be cauterized was first surrounded by a piece of adhesive plaster, then the paste was applied and covered over with gauze or cotton held in place with adhesive plaster. This dressing was left on for twenty-four hours. Frequently the dressing was applied for several days in succession until there was a marked gangrenous slough. One objection to this treatment was the slight amount of pain felt after the cocain had lost its effect, and another is the acute inflammatory edema which sometimes closes one or both eyes. The edema quickly subsides, however, after the paste is removed. In many cases the cosmetic results from the arsenic treatment are superior to those following surgical means, and this is an important point with growths on the face. Arsenic certainly seemed to have a selective action on malignant tissue, as they had tried it on two lesions that were not cancer, and where it only caused a trifling reaction. One was a large vascular mole, and the other a chronic localized infiltration from pus infection, and it had no effect on either except to cause slight congestion of the parts. It seemed to them that it was just as necessary to have experience in the use of arsenic as it was in the use of the knife in the treatment of cancers. One has to know something of the strength of the paste which should be used, the length of time to apply it, and the amount of tissue to be destroyed. One needs to know what accidents to fear, and also what appearances, apparently threatening, may be disregarded. The inflammatory edema, for instance, while very threatening looking, is in reality very innocent. The hole made by the cauterization is also very portentious looking, but it is wonderful what a small scar it leaves on healing. A large amount of bone may be laid bare at the bottom of a huge ulcer, and yet the lesion may heal kindly without any necrosis of the bone. Immediately after cauterization, on looking at the horrid disfigurement, one vows never to use arsenic again, but when the result is complete those vows are forgotten.

Dr. T. W. Huntington said that these cases show very satisfactory results of the treatment, but not more nor less than from the use of the knife. While recognizing these cases as a form of this disease, he hardly believes that they were the true, or the highest degree of, malignant epitheliomas. There is a difference in the malignancy brought about by the age of the growth and the conditions under which it appears. The location in these makes the diagnosis, in his mind, a little doubtful. He has removed many such tumors, with the same results, and with less pain and suffering. Several years ago, in conjunction with Dr. Cluness, he used the paste with considerable success. The results finally were not as satisfactory as he desired; some were bad, afterward showing a return with a high degree of malignancy.

Dr. H. M. Sherman voiced the opinion of Dr. Huntington as to the degree of malignancy of the disease, and he also prefers the knife as more certain and more thorough in its work.

Dr. Howard Morrow said they had treated several cases with formalin, by brushing it over the surface, but that there was much more pain than by the treatment with the paste. Several cases seemed to have gone on with questionable results, the disease spreading over the nose and forehead. The cases shown were probably not truly malignant. The tendency to malignancy usually increases with age.

Dr. D. W. Montgomery said that Dr. Huntington's statement regarding malignancy and superficial cancer of the face and nose is true. There is a difference of degree and of kind. Several years ago a woman, with a rodent ulcer close to the eye, came to the clinic. The ulcer was removed with the knife and a flap from the forehead filled in the incision. A year and a half afterward she returned and could not close the eye. There was paralysis. Metastases had occurred either from the knife or before the operation. She had been previously operated on in Stockton. This case was originally a typical rodent ulcer, but had degenerated and become malignant. Another case similar in character was seen some years ago, which he refused to treat with arsenic. The tumor had grown from a sebaceous gland. It was a nodular epithelioma which was removed by the knife. Four months after, the man returned with a scar too large and extensive for the area involved in the first operation. The scar tissue was taken out and found to be cancerous. He then sent the patient to Dr. Sherman, who removed some nodules from the neck, but whether they were cancerous or not was not demonstrated. The operation was an extensive one and required the removal of a large amount of tissue. The patient has remained well for three years. In such a case Dr. A. R. Robinson would have used paste. There are some cases of cancer of the face where the tumor is cut out repeatedly, which, unless treated by arsenic, formalin, chromic acid, or the *x*-ray, never heal up. There is one danger with the knife, namely, one is never certain as to the exact amount of healthy tissue that should be removed, for the tissues retract and draw away, and yet the operator believes that all the diseased structures have been cut out. He has seen such work frequently done. This is most common in superficial growths of the mucous membranes and of the skin. More surface than the area of the disease must always be destroyed. Arsenious acid seems to have a selective action on cancerous tissue.

Spina Bifida.

Dr. H. M. Sherman exhibited a specimen of spina bifida, showing a small cyst imbedded in the middle of the tumor, Morton's fluid was used for injection. After the operation the tumor contracted somewhat, and then remained stationary. The child became marasmic, seemed about to die, and was sent home, but subsequently came back for the removal of the tumor, which *pari passu* grew with the child. An incision was made through the skin and fatty tissues, and the sac tied off. He would not use Morton's fluid in many of these cases, though he believes that it does not interfere with the cord, and if it flows into the canal, does no harm. In this case, on account of the very small neck of the cyst and size of the tumor, the fluid was not allowed to enter the canal. Morton's fluid, in small tumors, covered by skin, may be advisable. If, after the use of the fluid, the mass still remains cumbersome and in the way, removal is best.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Infantile Colic.

Illoway, in *Phil. Med. Jour.*, states that the treatment of infantile colic is divided into: 1, *the immediate relief of the* infant, and 2, the removal of the exciting cause. As treatment for the first he gives *the following formula recommended* by Starr:

℞.	Sodii bicarb	gr. xv	1	
	Syrupi	℥ss	16	
	Aq. menth. pip. q. s. ad	℥ii	64	

M. Sig.: One teaspoonful as needed for a child of 1 month.

It may be made more efficient by the addition of two drops of aromatic spirits of ammonia to each dose, or in severe cases, one drop of spirits of chloroform. Or, in severe cases, he advises potassium bromid or chloral as follows:

℞.	Potassii bromidi	gr. xv	1	
	Chloralis hydratis	gr. viii		5
	Syrupi	℥ss	16	
	Aq. menth. pip. q. s. ad	℥ii	64	

M. Sig.: One teaspoonful at one dose and repeat if necessary two or three times at intervals of half an hour.

Illoway has found that infants readily become accustomed to the opiates and require increased doses from day to day; consequently he prefers the following *formula:*

℞.	Chloralis hydratis	gr. vi-x		36-66
	Mucilag. acaciæ	ʒi	4	
	Lac. asafetidæ	ʒii	8	
	Essent. anisi	ʒss	2	
	Aq. feniculi	ʒiii	12	
	Syr. rhei arom	ʒiss	6	

M. Sig.: One teaspoonful for a dose. To be repeated in one-half hour if necessary, for an infant from 2 to 6 weeks old. For older infants the dose of chloral can be increased if necessary to 1½ grains.

He states that he has found nothing superior to the milk of asafetida for immediate relief and the infants will take it very readily. It is innocuous and can be placed with perfect safety in the hands of the mother or nurse. He gives it in the following combination:

℞.	Lac. asafetidæ	℥ss	16	
	Syrupi mannæ	ʒiiss	10	
	Essent. anisi	ʒss	2	
	Syr. rhei aromat	ʒi	4	

M. Sig.: One teaspoonful at a dose.

He states that the administration of a few teaspoonfuls of warm sweetened fennel tea after administering the above will not only do away with the taste in the infant's mouth, but to some extent increases the action of the asafetida.

Dewee's carminative, which was official in the U. S. P. in 1880, and known as mistura magnesiæ et asafetidæ, and which was mentioned by Illoway in his article, is composed *of the* following:

℞.	Magnesii carbonatis	ʒiss	6	
	Tinct. asafetidæ	ʒiiss	10	
	Tinct. opii	m. xix	1	30
	Sacchari	ʒiiss	10	
	Aquæ q. s. ad	℥iv	128	

M. Sig.: One teaspoonful, to be repeated in half an hour if the infant is not relieved. This sized dose is calculated for a child 2 weeks or 1 month old.

Occasionally, he states, in infants with a peculiarly sensitive tract, an opiate may be required and the camphorated tincture answers best prescribed as follows:

℞.	Tinct. opii camph	℥i	32
	Aq. menthæ pip	℥v-℥vss	160-175
	Syr. rhei arom	℥i-℥iss	32-48

M. Sig.: One teaspoonful, to be repeated in half an hour if necessary. A third dose can be given in two hours.

In colic due to over-feeding or to indigestion, to constipation or to improper food, the suffering of the infant is quickly relieved by the following:

℞.	Misturæ rhei et sodæ	℥ss	16	
	Spts. etheris comp. (Hoffman)	m. xl	2	66
	Syr. rhei arom. q. s. ad	℥i	32	

M. Sig.: *One-half teaspoonful, to be repeated in one-half to* three-quarters of an hour for an infant 3 or 4 weeks old. For younger infants the dose is fifteen to twenty drops; for older ones, from one-half to one teaspoonful, according to age.

REMOVAL OF THE CAUSE.

If due to flatulency where the digestion is retarded, Starr advises the administration through the whole colicky period of vinum pepsini, three times a day in fifteen-drop doses.

The following is recommended by Thompson for the same condition:

℞.	Sodii bicarb	gr. iii	18
	Papainæ	gr. i	06

M. Ft. chartula No. i. Sig.: One such after each meal.

Or,

℞.	Sodii bicarb	gr. xlv	3
	Spts. ammon. arom	m. xv	1
	Spts. chloroformi	m. xv	1
	Syrupi	ʒiiss	10
	Aq. destil. q. s. ad	℥ii	64

M. Sig.: One teaspoonful after each meal.

Incontinence of Urine in Children.

J. Blake White states that *the following combination* is of good service:

℞.	Sodii benzoatis		
	Sodii salicylatis, āā	gr. xxx	2
	Tinct. belladonnæ	m. xv	1
	Aquæ destil. q. s. ad	℥iv	128

M. Sig.: One teaspoonful in water four or five times a day.

The quantity of sodium salicylate may be increased to double the amount if necessary.

Methylene Blue in Treatment of Malaria.

Dr. M. Dunn states that there is no remedy equal to methylene blue in cutting short malarial fever. He prescribes it as follows:

℞.	Methylene blue	gr.ii	12
	Quininæ sulphatis	gr. ii	12
	Ferri carbonatis	gr. i	06
	Acidi arsenosi	gr. 1/50	0012

M. Ft. cap. No. i. Sig.: One such capsule every three hours.

Sodium Persulphate in Tuberculosis.

Garel, of Lyons, as noted in the *Jour. of Tuberculosis*, states that this salt can exert a very remarkable influence over the appetite and digestive organs, and as an oxidizing agent it excels even arsenic and vanadium, and is much less toxic. The *sodium persulphate should always be taken on an empty* stomach, one and one-half hours before eating. According to Nichols, *one dose of 2½-5 grains (.15-.30) in twenty-four* hours suffices. Its administration is indicated only in the earlier stages of the disease to arouse the appetite and to promote nutrition in anorexia and weak digestion.

Treatment of Acute Gout.

The following treatment of acute gout is recommended by Bartholow:

A sufficient quantity of colchicum should be given to increase the secretion from the skin, the intestinal mucous membranes and the kidneys, but nausea and vomiting should be avoided. Better results are obtained when it is combined with an alkali, as:

℞.	Vini colchici sem.	ʒiii	12	
	Spts. ammon. arom. q. s. ad	℥ii	64	

M. Sig.: One teaspoonful every three hours in water.

Or,

℞.	Tinct. colchici sem.	m. xx	1	33
	Potassii bicarb.	gr. x		66
	Aq. pimentæ q. s. ad	℥i	32	

M. Sig.: At one dose, to be repeated every three or four hours.

The following combinations are recommended by Sir Henry Halford:

℞.	Ext. colchici radicis	gr. vi		25
	Pulv. ipecacuanhæ et opii			
	Ext. colocynth. comp., āā	gr. xii		75

M. Ft. pil. No. xii. Sig.: One pill night and morning.

Or,

℞.	Ext. colchici rad.	gr. x		66
	Pulv. digitalis			
	Ext. colocynth. comp., āā	gr. xx	1	33

M. Ft. pil. No. xx. Sig.: One or two pills, to be taken three times a day.

Quinin as an Antipyretic.

Egbert, in *Merck's Archives*, favors the combination of quinin with acetanilid as antipyretic in the earlier stages of inflammatory diseases. In his opinion a fluid mixture is preferable:

R.	Quininæ sulphatis	ʒi	4	
	Acetanilidi	ʒi	4	
	Elixir arom.	℥i	32	
	Syrupi (chocolated) q. s. ad	℥iv	128	

M. Sig.: One to two teaspoonfuls every three or four hours.

By combining quinin in small doses with other cinchona alkaloids the effect of the dose is augmented. He recommends the following:

℞.	Quininæ sulphatis			
	Cinchonæ sulphatis			
	Cinchonidinæ salicylatis, āā	gr. xxx	2	

M. Ft. cap. No. xxx. Sig.: One to two capsules every three or four hours.

Thiocol in Chronic Bronchitis.

Dr. J. A. Goldmann, of Vienna, claims to have obtained splendid results in treatment of chronic bronchial catarrh with thiocol (the potassium salt of guiacol-sulfonic acid) prescribed as follows:

℞.	Thiocol	ʒiiss	10	
	Syr. aurantii q. s. ad	℥iii	96	

M. Sig.: One teaspoonful for a child, or one dessertspoonful for an adult, three times a day in milk or coffee.

As a Resolvent of Tuberculous Glands.

Descroizilles, as noted in *N. Y. Med. Journal*, recommends the following as a local application:

℞.	Tinct. iodi	gr. xv	1	
	Magnesii sulph.	ʒiiiss	14	
	Sodii chloridi	ʒx	40	
	Aquæ destil.	℥ivss	144	

M. Sig.: To be applied locally on compresses.

A Lotion for Checking Night Sweats of Phthisis.

Herschfeld reports excellent results from sponging the body with the following mixture:

℞.	Balsami peruvianæ	gr. xxx	2	
	Acidi formici			
	Chloralis hydratis, āā	ʒiiss	10	
	Alcoholis	℥vi	192	

M. Sig.: Sponge the patient's body at night.

Acute Bronchitis in Children.

The following prescription is recommended by A. Agramonte

℞.	Solutionis ammon. acetat	ʒiv	16	
	Spts. etheris nitrosi	ʒiss	6	
	Syrupi ipecacuanhæ	ʒiss	6	
	Syrupi senegæ	ʒi	4	
	Syrupi limonis q. s. ad	℥iv	128	

M. Sig.: One teaspoonful every four hours.

The above combination will produce elimination from the skin, kidneys and bronchial mucous membrane.

Correction: In last issue, on p. 594, the second prescription under "Treatment of Blepharitis," should have Vaselini ʒiii instead of gr. iii.

Medicolegal.

Seven Thousand Dollars for the Loss of an Eye.—The Court of Civil Appeals of Texas, says, in the case of the De La Vergne Refrigerating Machine Company vs. Stahl, that the verdict here returned of $8000 is much larger than that in any case which it has been able to find, or which counsel seem to have been able to find, involving the loss of an eye, with the usual consequences of such injury. Here the party seeking to recover damages therefor was a young man, a mechanic, 24 years of age, when hurt. And while the court considers $8000 as excessive compensation in such a case, it holds that the loss of an eye is a serious injury, and says that it will affirm the judgment if a remittitur of $1000 be made from the $8000.

Extent of Liability of Seller of Patent Medicines.—The case of West vs. Emanual was brought by a mother to recover from a druggist damages for the death of her daughter, alleged to have been caused by a headache powder, sold to her by the druggist. At the close of her case, and on motion of the defendant, a compulsory nonsuit was entered. This, the Supreme Court of Pennsylvania holds was proper, as the evidence introduced failed, in its opinion, to establish or disclose a cause of action. The powder, it explains, was a patent or proprietary medicine, sold by the manufacturer to drug stores, and by them sold to their customers. And in the sales of patent or proprietary medicines furnished by the compounder of the ingredients which compose them, the court holds, the druggist is not required to analyze the contents of each bottle or package he received. If he delivers to the consumer the article called for with the label of the proprietary or patentee upon it, he can not be justly charged with negligence in so doing.

Prohibiting Additional Hospitals Where Built up.—A Pennsylvania act of 1899 for the protection of public health, prohibits the establishing of maintenance of additional hospitals, pest-houses, and burial grounds in the built-up portions of cities. In construing this, in the case of Commonwealth vs. the Charity Hospital of Pittsburg, the Supreme Court of Pennsylvania holds that it was properly decided in the court below that the phrase "built-up portions of cities" must be understood in its ordinary and popular meaning, and with reference to the object of the act, viz., the protection of the public health, the object of the act being presumed to be to remove supposed sources of contagion from immediate contact with a large population. It also approves of construing the word "additional" to refer to new buildings not already established, and not to mean in addition to the total number then maintained in the whole of the city. It also seems to think that the act is single in its purpose, namely, to protect the public health, and at the same time a general act, for the protection of the public health throughout the commonwealth, regulating the location of the institutions in questions by prohibiting them in all the more populous places of the state, down to a certain line, where the supposed evil does not exist. Nor does it consider that the act deprives a hospital of its property, or the use of it, without due process of law, or denies to it the equal protection of the law, in contravention of the federal constitution.

County Not Liable for Treatment of Pauper Inebriate.—The Supreme Court of Wisconsin holds, in the case of the Put-ney Brothers Company vs. Milwaukee County, that neither the county board no any county officer has authority under any specific statute of that state to contract with a private person or corporation for the medical treatment of a pauper for what is termed "inebriety," and entail a liability therefor upon the county, his board being simply a minor incident of the treatment. Inebriates may, indeed, it says, be received into county asylums, under certain restrictions, and may be committed to a county poor-house, and the county become liable for their care in whole or in part, but the statutes seem to go no further. Thus, it appearing that the legislature of Wisconsin has provided certain methods by which inebriety or habitual drunkenness may be dealt with, the supreme court thinks it plain that it has excluded other methods, and that the general provisions requiring the county or town to care for and relieve paupers refer to necessary food, clothing, ordinary medical treatment, and the like, and not to medical treatment looking toward the cure of inebriety as a disease. There is, therefore, it insists, no authority resting in any officer or public body to incur liability for such treatment. And such being the case, there can, it holds, be no ratification by the county, as a county can not ratify the unauthorized acts of its agents which are beyond the scope of its corporate powers.

Liability for Aggravation of Latent Disease.—The case passed upon by the Supreme Court of Colorado entitled the City of Denver vs. Hyatt was brought by the latter party to recover for injuries alleged to have resulted from a fall caused by a defective sidewalk. The jury was instructed, in effect, that, if the plaintiff was predisposed to a disease which was aggravated or accelerated by reason of the accident, she was entitled to recover the damages necessarily resulting from such aggravation or acceleration; in other words, that to the extent she was caused to suffer from the effects of a latent disease, above that which she would have suffered had it not been for the accident, she was entitled to recover damages. This, the supreme court holds, was not error. The sidewalks of a city, it says, are for the use of those with organic predisposition to diseases as well as for the healthy and robust and any injuries which the former sustain by reason of defects in such sidewalks, which result in aggravating an already diseased condition, are results for which the city must respond, if otherwise liable. The evidence was clear at the time of the trial the plaintiff was suffering severely from some internal difficulties, which were manifest for the first time shortly after the accident. These troubles were of such a serious nature as to render her practically helpless. What particular internal organs were affected was not clear. The physicians called did not agree upon this proposition. Neither were they a unit as to what might have been the proximate cause of this condition. One of them gave it as his opinion that her internal condition was caused by the fall. None of the others stated directly that it was not, but they stated that they had never known such a condition as she presented due to an accident, or that such condition was not necessarily attributable to the accident. From other evidence it appeared that the plaintiff prior to the accident was a healthy and vigorous woman, and had never suffered from a deranged condition of any internal organs prior to that time; that shortly after the accident, as before stated, she was affected internally. Now, this fact, in connection with the testimony of the physicians, the supreme court thinks, was amply sufficient to warrant the conclusion by the average layman, and to sustain a jury finding, that the deranged internal condition which she manifested at the trial, and which had existed a long time prior thereto, was caused by the fall.

Not a Case for Fee-Bill Charges.—The Supreme Court of Wisconsin says that, upon the question of the value of the plaintiff's services, in the case of McNamara vs. McNamara, the jury seem to have gone widely astray. This was a controversy between son and father, both of whom were practicing physicians. The son claimed $12,000 to be due him for consulting and advising with his father in his practice for a period of five years and ten months, alleging an express promise by the father to pay what such services were reasonably worth. The answer was a general denial, with a counterclaim for money advanced. The son kept no books of account, and during the years in question never made a memorandum of a single case he treated, or concerning which he counseled or advised his father. His guess was that his father called upon him on the average of four times a week, and that he counseled with him as to four cases at each visit. His estimate was that he advised with his father concerning 1000 cases each year, and that his services were worth a little less than $2 for each case. Three physicians were called as experts for him, and were asked a hypothetical question similar to the following: "Q. Doctor, if the defendant in this case consulted with the plaintiff in a professional capacity on an average four times a week, and at each consultation discussed four patients on an average, or say sixteen to eighteen cases a week, and in consultation the plaintiff would prescribe for the different parties, give advice as to the medicine to be given, how much, and the general treatment, and all such other advice and information as is incident to a consultation for treatment, those cases being of a syphilitic nature and venereal character entirely, or 90 per cent. of them at least, what, in your opinion, would such services be worth per year?" One answered, in the neighborhood of $4000 per year; going according to the fee-bill fixing rates for consultation. The second testified that he would charge $4160 per year for such services. The third thought from $2 to $5 a consultation would be a reasonable charge . But that such testimony was of no value in arriving at a correct conclusion, the Supreme Court thinks evident from the fact that the hypothetical question did not cover the material facts in the case. The relation of the parties, the circumstances under which the services were rendered, the time employed, the nature and extent of the consultation, and all the circumstances surrounding the service, it holds, were material in arriving at a reasonable answer. The attempt to apply fee-bill charges to such a situation, it declares, was absurd. On this account, and because it considers that prejudice was aroused and no proper foundation for the recovery allowed was found in the evidence, it grants a new trial notwithstanding that the $11,000 verdict returned by the jury was cut down by the trial judge to $6000.

3. **Infantile Scurvy.**—The etiology of scurvy in infants has been studied by Griffith, who reviews the statistics and also reports a number of personally observed cases. The points of interest to which he calls attention are: that there is a generally accepted view that patented foods often produce infantile scurvy and some cases show that recovery may follow their withdrawal without other treatment. Whether this is because they are deficient in certain ingredients or whether they commonly contain or are derived from starch, remains to be determined. The cases also indicate that the sterilization of milk is capable of producing scurvy though this is a less prominent etiologic factor. It is shown that scurvy can develop on a diet of milk, which has not been long heated or which is even raw, and in which case we are lead to suspect the action of a low percentage of proteids. Some of the cases also show that fruit juices may produce a cure without any change in the diet. In conclusion he remarks that while there are dietetic factors, the individual element is markedly present in this disease: what is one baby's meat is another's poison.

6. **Chloretone.**—Stevens gives his experience with this drug and concludes that we have in it a special hypnotic of moderate power, rarely giving rise to unpleasant after-effects, but of which a tolerance is quite readily acquired, and it should be adopted for use in cases of insomnia, unattended with pain, high fever, or pronounced nervous excitement.

7. **Sputum Examinations.**—Fussell insists on the necessity and value of sputum examinations, describes the technique, and discusses their practicability for the average practitioner. To show their value three cases are reported. He maintains that it is perfectly practicable for any physician possessing a microscope with a moderately high power, or with an oil-immersion lens, to make the examinations himself, and describes the simpler procedure.

8. **Rectal Resection Per Vaginam.**—Murphy describes and illustrates his method of excision of the rectum through the vagina, and reports five cases. His conclusions are that the advantages offered by this route are: 1. The sacrum and posterior bony wall of the pelvis are not disturbed. 2. The field of operation is as extensive and the anatomical parts as accessible as in any transsacral operation. 3. The peritoneal cavity is opened in both the vaginal and sacral operation, and in neither is it a source of great danger. 4. The diseased tissue is more accessible for inspection and the extent to which the operation may be carried upward is as great, if not greater, than by the sacral route. 5. The peritoneum may be drained freely through the vagina. 6. A perfect end-to-end approximation either by sutures or with the use of a button may be secured. The preferable method is by interrupted silk suture because, as there is no peritoneum on the sphincteric segment, failure of union with the button is to be feared. 7. The sphincter is retained and the peritoneal body is restored. There is a diminished action of the levator ani muscle. 8. When operation is complete, the parts are practically in their normal position. He remarks that he has performed the same operation on male cadavers and found, by splitting the sphincter directly through the median line anteriorly and posteriorly cutting back to the coccyx and opening the retrovesical fold of the peritoneum, practically the same field for operation may be opened as in the female, several inches of bowel be dissected and end-to-end union secured. Either anteproctеal or postproctеal drainage may be used. The cut ends of the sphincter are united anteriorly and posteriorly and the lateral nerve-supply on the other side is not disturbed.

12. **Army Pathologic Laboratories in the Philippines.**—The army pathologic laboratories on hospital ships and at Manila are described by Curry, who gives general remarks on the diseases of the Philippine Islands. He speaks of the special embarrassments in such laboratories in the tropics, on account of the frequent contamination by air organisms and the rapid putrefaction processes in cadavers. The bacterial flora of the tropics is, he says, as rich and varied as its botanical flora, and a great many organisms are met with that were hitherto unknown. As regards the climate, he thinks the Philippines are not specially unhealthy for a tropical region.

13. **Dysenteric Diseases in the Philippines.**—Out of over 20,000 cases treated at the First Reserve Military Hospital at Manila, there were 1999 cases submitted for dysentery and 2186 for diarrhea, a total of 4185 or over 21 per cent. of the total. About one-half of the cases of diarrhea were probably dysenteric, making a total of 3000 cases, of 15 per cent. of total admissions. Dysentery is responsible for the highest mortality among the troops and is, moreover, a persistent disease occurring repeatedly after the first attack. It is generally traced to impure drinking water. Of the coincident affections he mentions malaria, and also typhoid fever, pneumonia and tuberculosis which appear in a small percentage. The amebic type of dysentery is the predominating one, occurring in a little over 60 per cent. of the cases of those that come to autopsy, and is responsible for more deaths than all the other types combined. Abscess of the liver has been found in about 16 per cent. and general peritonitis in about 25 per cent. due to perforation of ulcer or rupture of the abscess. In addition to this there was general peritonitis in one case, without perforation of the bowel, the infection passing through the thin base of the ulcer in the cecum. In all cases of abscess active ameba were demonstrated both in the abscess contents and the contents of the large intestine. The question as to whether the ameba is of primary or secondary origin is discussed, and the author favors the view that it is the principal causative agent in at least one type of the disease. In several cases the bacillus of Shiga and Flexner has been found in cultures. He has not had much experience with the antidysenteric serum of Kitasato, though its results are in Japan believed to be of value. He recognizes two distinct types in the Philippines, the amebic dysentery and the acute dysentery, in a number of which the Shiga bacillus was found. In addition to this there were cases of subacute and chronic dysentery in which neither the amebæ nor bacilli occurred.

14. **Uterine Fibroids.**—Gage reports a method which he has followed in 50 cases. He has resorted to dilatation, and

curettement in 5, with other measures to some extent, and he has operated by morcellation for submucous fibroids projecting into the uterus in 15 cases, and while he has had no deaths he has had serious septic complications in several. In 3 cases he has removed the tubes and ovaries with good results. In 2 he removed the uterus by the vaginal route, one following an unsuccessful curettement and the other for supposed carcinomatous degeneration. He would not choose the method for this purpose, but it is applicable for the removal only of small tumors and is not so satisfactory as the operation from above. He has performed abdominal hysterectomy 25 times with 3 deaths; two of them he thinks were due to defects of technique, in lack of knowledge of any other source. His method of operating is to cut the broad ligament between two clamps down to the attachment of the round ligament, divide the peritoneum through the uterus from side to side at this level and strip it back keeping close to the uterus until he can feel the uterine arteries between the peritoneal folds, secure with silk ligatures and then amputate the cervix. He cauterizes the divided uterine canal, securing the ovarian arteries and vessels of the round ligaments and finally uniting the anterior and posterior layers of the peritoneum by continued sutures from one side of the pelvis to the other. The most important steps are, he thinks, the absolute control of all hemorrhage about the stump so that there should be no accumulation of clotted blood from the space between the stump and its new peritoneal covering and the treatment of the uterine canal. During the past he has tried, whenever possible, to leave at least one ovary, but confesses failing to observe any special advantage in the results. The operation with its progressively diminishing mortality and completeness is almost ideal when performed for the relief of symptoms definitely known to be due to fibroid. It would be ideal, but for the fact that it unsexes the patient, and this makes it objectionable in young women. As regards myomectomy, the only great danger is from hemorrhage and the supposed difficulty of controlling bleeding from torn uterine muscles, simply a lack of technique, and every year is bringing additional testimony to the unsoundness of this objection. He performed myomectomy only six times, but with the very best results. It is especially applicable in cases of young women after it is made clear that the fibroid is steadily growing.

15. **Dysbasia Intermittens.**——This condition, which consists in intermittent lameness following exercise, is described by Putnam, who reports a case. and confesses to feeling a little doubt as to the correctness of the generalization of Erb and Charcot that the condition is due to the fact that when the muscles are in use a very unusual supply of blood is needed, which can not be supplied on account of arterial defects, or that vascular cramp is induced. In his case a careful examination of the patient's arterial circulation in the involved foot was made before the treatment was begun, and afterward, and no special change of conditions noted. He is inclined to think that perhaps vascular spasm is the best explanation. The treatment employed by him was galvanism followed by faradism following the indications laid down by Erb. After the bath treatment had been abandoned, the patients undertook to give himself a kneading and massage of the calves of the legs, and improved. Possibly the influence of warm weather had something to do with the improvement.

16. **Causes of Infectious Diseases.**—Doty pleads for more careful research into the origin of any case of infection, and, if well marked cases can not be found, says we should look for mild or convalescent ones. The physicians should be more careful to disinfect everything that the patient had used or had. He is satisfied that the clothing of well persons and cargoes of ships are rarely the means of transmitting disease, but the danger from mild, ambulant and convalescent cases which pass unnoticed should be recognized.

17. **Floating Kidney.**—Morris describes the operation performed by him for the last two years, for which he does not claim anything excepting that it seems rational and has been up to the present time the most desirable in its results in his hands. In this operation a flap of capsule including the larger part of the mesial surface of the kidney is incised with a scalpel and the flap of capsule then stripped up from the parenchyma but remaining attached at the convex border of the kidney. The flap of capsule is drawn through a slit in the psoas muscle or in the quadratus muscle, as one chooses, and is there sutured in place. This brings bare parenchyma also in contact with the psoas or quadratus fascia, where it forms a firm connective tissue attachment. The operation avoids the necessity for passing the suture through the parenchyma of the kidney and he has had no reports of the recurrence of the difficulty in his cases up to the present time. In his general remarks on floating kidney he maintains that this condition is so common that probably every practitioner has a number of patients under his care suffering from this cause. The reason it is not more often clearly recognized at the autopsy is that the organ returns to its place and becomes fixed there by rigor mortis. In some instances the condition gives no trouble, in others there are distressing complications; in others still those of general enteroptosis. Cases for operation, according to his view, are those which continue to produce important symptoms after the diagnosis has been well made and abdominal support and general medical treatment tried without effect. The method of examination practiced by him is that prescribed by Israel. A line is drawn parallel to the middle line of the abdomen, distant from the middle line of the abdomen as far as the point in the middle of Poupart's ligament and extending to the costal border. In examining the right kidney the fingers of the right hand are placed on the upper extremity of this line, the left hand at the same time lifts the quadratus lumborum muscle. The fingers of the right hand are depressed more and more with each expiration of the patient until the lower pole of the kidney can be felt or at least approximated. The patient is then asked to take a deep inspiration, when the kidney, if loose will slip out beneath the examiner's fingers very distinctly and can often be carried to a point below the navel. The loose kidney commonly falls into its normal position with the patient in a recumbent position, but often is discovered at some other point in its line of excursion.

18. **Scarlet Fever.**—The subject of convulsions with scarlet fever is discussed in connection with a case which is elaborately reported by Hayd. He summarizes his deductions from this case, in substance as follows: 1. Every case of scarlet fever is a law unto itself. 2. Convulsions may and do occur when least suspected. 3. The urine should be frequently examined, not only as to specific gravity and albumin, but urea calculations should be often made. 4. Mere specific gravity is not a sufficient indication as to the amount of urea eliminated, as yet it may be retained in poisonous quantities; moreover, a large quantity of water may be voided with fair specific gravity and yet convulsions occur. 5. Albumin need not be present, or only a trace can be found, and yet convulsion occurs, but it will be found perhaps in great amounts following it. 6. Only the most digestible food and nourishment should be given, if possible such as produces little gastric and intestinal putrefaction, the best being milk, because the amount of toxalbumins and putrefactive residue is reduced to a minimum. 7. If milk can not be digested or will not be taken, no food should be administered for days by the stomach, but the patient be allowed an abundance of water and nourishment by nutrient enemata. If broths are borne, chicken broth made according to the directions of Dr. Pryor of New York, as found in his book, is a pleasant and nutritious food. 8. In any severe case of convulsion only a small amount of food by the stomach should be given at any one time, and frequent urea calculation should be made to see that the proper quantity of urea is eliminated, and if it is not increased after the ingestion of food, the food must be withheld or such be substituted as will not interfere with urea excretion. 9. If gastric irritability exists, give the stomach and bowels, rest, which also rests the kidneys and permits them to rehabilitate themselves either in function or to develop new renal secreting cells. Scarlatinal nephritis is a desquamative process and epithelial cells are no doubt often quickly formed. 10. The amount of urea passed in twenty-four hours differs in different individuals ,and it may be

roughly stated that an excretion of 10 gms., or 150 gr. of urea for a child 10 years old, weighing 60 pounds, will protect her from convulsions. His patient is passing over 500 gr. every twenty-four hours. 11. Hypodermoclysis is a very valuable and safe method to introduce water into the system, and, with the proper precautions, as much as two or three pints may be used without danger of severe abscess formation. Decinormal salt solution should be used, first boiled, and the skin be thoroughly disinfected by washing with soap and brush, and again with a bichlorid solution—1 to 2000—and subsequently with alcohol. The needle and fountain syringe, with tubes, should be placed in boiling water and boiled for a few minutes to ensure perfect cleanliness. 12. Enteroclysis or the introduction into the bowels of a number of quarts or even gallons of water, with a temperature ranging from tepid water to 80 degrees, if much fever be present. should be employed once or twice during the twenty-four hours. 13. Strychnin and digitalin are the most valuable heart stimulants and brandy the best food and diffusible stimulant.

19. **X-Ray Diagnosis.**—The correct mechanical principles employed in securing the data on which the diagnosis of the Roentgen method is based, insures, according to Leonard, absolute results when the technique of its employment is correctly understood and the data obtained by its use rightly interpreted. The advantages of the method are not only the recognition of the disease known to be existing, but multiple fractures are often shown where only one was suspected. The exact line of fracture is determined and more correct information is obtained without manipulation, saving the patient unnecessary pain and causing no further traumatism to the tissues. This increased facility in diagnosis is not the limit of its usefulness, however, the accuracy of setting and efficiency of fixation apparatus or other methods of treatment can be demonstrated and the necessity of otherwise operative interference can be diminished. The Roentgen method has created a higher standard by which the treatment of fractures may be judged and practitioners can not be said to have employed all the means and knowledge without the use of the *x*-ray. The skiagraph has been admitted as evidence and suits for damages will undoubtedly be based upon its evidence. The safety of practitioners lies in its employment to prove that reduction and fixation have been accomplished or, if not, proof that he suggested it to the patient and was refused its employment. It can never, however, form a basis on which the amount of damages is assessed, which will depend on functional disability and loss which the patient has sustained. Whenever the skiagraph is introduced as evidence the defendant should demand the privilege of having a similar examination and should employ expert testimony to fully explain its meaning to the jury. One great advantage of the method is the possibility of establishing an absolutely negative diagnosis, which is valuable in many cases.

20. **Adenoids.**—The mischief due to adenoids consists, according to Woodward: 1, in the excitation of aural disease; 2, their effects on the patient's general health. He reviews the symptoms dependent on the condition, their development, and the accessory symptoms, including in the latter chorea, epileptiform attacks, and deafmutism. As regards treatment, he thinks we should not wait for the retrogressive hyperplasia which occurs during adolescence, because, prior to this, serious damage may be done. The operation, he claims, is not necessarily dangerous, and while hemorrhage is profuse it ceases spontaneously. Anesthesia is, he thinks, the greatest danger, and he avoids the use of it when he can. The only aftertreatment required is cleanliness of the wound, cod-liver oil, iron and fresh air. He also remarks on the condition of hypertrophy of the faucial tonsils and operates for their removal. Up to the present time he has not seen a patient in whom tonsillotomy had been done who had not derived some benefit from the operation.

25. **Carcinoma from Senile Warts.**—Broome reports two cases of carcinoma developing from senile warts, one of which was treated by local measures which seemed to be so effective that he concluded the carcinoma was practically destroyed and closed the breach made by the carcinoma, by plastic operation. Union took place by first intention. The cosmetic effects were entirely satisfactory and there is no evidence of return, though only three months has elapsed. He discusses the etiology of these malignant growths, and suggests the probability of the parasitic nature of the growth.

26. **Suprapubic Cystotomy.**—After giving the history of the operation, Carpenter reports several cases and remarks in regard to the method. He says, bend, do not tie down the penis when the bladder is distended. Cut down, not up, in opening the bladder in suprapubic cystotomy. Feel for the knot of the urachus, and cut below toward the neck. The peritoneum does not extend below this point. The danger of over-distending the ulcerated, attenuated, sacculated bladder is mentioned and, if necessary, he advises to cut open the peritoneum, having the incision repaired after the pathologic condition has been removed. The operation should be done to remove calculi, foreign bodies, tumors, for stabs, gunshot wounds, rupture of bladder, drainage in the bladder, the passage of urine in stricture, etc. In stone cases the operation of election is Bigelow's, but the stone may be too hard to crush. For polypus, papilloma, removing hypertrophied lobes of prostate, foreign bodies, etc., for cure of peritoneal fistula, which can not be otherwise cured, the suprapubic is the best and most successful method. One must not forget to keep in the mesial line and avoid veins in the prevesical space. It may be necessary to divide, transversely, the thick fascia forming the linea alba close to the symphysis pubis, also to divide the recti muscles transversely if the resistance is so great as to interfere with the rest of the operation. The bladder, after having been opened, is held by fixation forceps, or sutured to the wound, as deemed best; one or two fingers in the rectum to open the posterior wall may be necessary. Hot water is the best agent in bladder surgery. When the bladder is healthy and the wound aseptic the bladder wall may be sutured and get preliminary union, but if it is diseased or engorged no attempt should be made to suture it. Drainage should be used if the case demands, and the patient kept scrupulously clean.

29. **Renal and Vesical Calculi.**—Harrison remarks that it would be interesting to know if observations have been made as to whether the color of the urinary calculus apart from its chemical compositon exercises any influence on the shadow cast by the *x*-ray. It has occurred to him that if such were the case, it would be possible to bring this about artificially. In a recorded case he found that a white phosphatic stone was deeply stained blue by the patients having been treated previously with a course of methylene blue for cystitis, and he has seen other similar cases since and wondered whether different degrees of intensity in the radiograph of oxalate of lime calculi were explainable in this way. He suggests this as a practical point. The stone detected by radiography may permit of a delay in operating, without detriment, which is an advantage.

35.—This article also appears elsewhere. See ¶26, above.

47. **Autopsychorhythmia.**—This is the name given by Hughes to a symptom of repetition of certain words and phrases, a sort of repetition psychoneurosis. He refers to a number of cases and compares it with the echolalia and other symptoms. The form of insanity toward which this condition tends is, in his opinion, that in which imperative conceptions predominate or have predominated in the initial stage. Its pathologic lesion is evidently in the mind area of the brain cortex, not *focalized exclusively in the* speech area. 'It is a psychic and not a purely psychomotor involvement.

49. **Malthusianism.**—Alexander discusses Malthusianism and its influence on civilization, maintaining that, on the whole, it has been a decidedly potent factor in the advancement of the race, notwithstanding the fact that Malthus underestimated the increase of subsistence resultant on the ultilization of waste and over-estimated the human rate of increase.

37. **Chromic Acid.**—Shaw reports a case in which chromic acid was used for condylomata of the genitals, and produced decided toxic symptoms, nausea, rapid pulse, cold extremities, perspiration, etc. The dressings were immediately removed, but the conditions continued for thirty-six hours and then the patient gradually returned to her normal state. He finds little literature on the subject in text-books, though a similar case with more disastrous results was reported a few years ago by Dr. J. Wm. White, the strength of the solution in both cases being the same, 100 gr. to the ounce.

52.—See abstract in The Journal of January 12, p. 126.

53.—Ibid.

54.—Ibid.

55.—Ibid.

56.—Ibid., p. 127.

57.—Ibid., p. 126.

58.—**Colostomy**—Finlayson argues for the benefits of colostomy, maintaining that it should never be performed without fully informing the patient as to the consequences, but also holding that it will relieve the conditions in hopeless cases, make life comfortable and even prolong it. In many non-malignant cases it may often make life endurable and cause little inconvenience or embarrassment. He favors the operation on the left side. The special point is that the diagnosis and prognosis must point unerringly to its necessity, and it should be performed as low down as possible so that the nutritive processes may be nearly completed. The technique of the operation is not described.

65. **Electricity in Genito-Urinary Disease.**—The disorders in which Walling thinks electricity valuable are impotence, catarrhal condition of Cowper's glands, spermatorrhea, enlarged prostate, varicocele, hydrocele, stricture, gonorrhea and syphilis. In cases of sexual weakness anesthetic areas receive the cathode and all irritable portions the anode whether the current be galvanic or faradic. Sittings may ge given of fifteen minutes three times a week. In enlarged prostate he uses potassium iodid solution directly to the gland by the cathode. to produce cataphoresis. In hydrocele he claims electrolysis presents a perfectly satisfactory method of treatment. The technique of the different methods is given in detail.

76. **Arthritis Deformans in Infancy.**—Moncorvo reports a case of a child 5 months old showing this condition, and notices the literature. He thinks there is no doubt as to the influence of heredity and rather favors the microbean theory of the condition. The symptoms are noted. The affected joints are mostly symmetrical and painful; acute and subacute conditions become attenuated and are followed by articular lesions which have a slow course or remain stationary. There is more or less marked anemia and he has also found a sensible diminution of hematin, and reduction of hemoglobin which, according to Bannantyne, reveals the action of the toxins developed by the bacilli. Symmetrical invasion of joints makes a clear distinction from gout. In infantile polyarthritis the general character is benign and a happy termination is the rule, though in some cases it may last into adult life or old age. As regards treatment, iodotherapy and electrotherapy are the surest means to combat infantile polyarthritis deformans.

78. **Influenza.**—Barnes compares the epidemic in St. Louis, in 1899 and 1900, with that of the present winter, which last he considers is causing more painful symptoms and more general complications. The most usual symptoms are general malaise, stabbing sensation in the region of the tonsils, with aching bones, and frontal headache. The other symptoms that may occur are in some cases complete aphonia, present for several days, cough, hoarseness, frequently pain in the chest and abdominal muscles, and the tongue is white but not furred, the breath very offensive, but the marked odor of the body noted in the epidemic in the preceding winter is not present. The bowels in most cases are normal; the urine dark, fever slight, cervical glands not enlarged, ear symptoms in some cases quite severe, though not so general as last winter. The treatment is largely symptomatic: quinin in small doses, with kryofin to relieve the pain, heroin for the cough, in 1/12 gr. doses every three hours, with ammonia chlorid and pilocarpin. The usual cough remedies do not seem to be effective. Local treatment is of great value. As to prevention, he advises the patient to remain indoors after dark, eat wholesome digestible food and dress properly, keep the bowels open, use but little liquor, and to secure plenty of rest and fresh air.

87. **Hysterectomy.**—Robinson reports the method he follows after performing vaginal hysterectomy, which he thinks has its advantages, leaving the oviducts and ligaments *in situ* and the utero-ovarian vascular circle intact. The patients make excellent and painless recoveries. The operation is performed as follows: The cervix is seized by traction forceps and a circular incision through the vagina is made about the neck, after which the anterior and posterior uterine surfaces are freed, and the oviducts, ovaries and broad ligaments also freed from the abdomen if necessary. Then, with a strong pair of scissors, the uterus is split from the cervix to the fundus about one-half inch from the lateral uterine border toward the median line on each side. The external uterine tissues of the lateral segments thus left *in situ* are closed by bringing together the cut peritoneal edges with sutures about a half inch apart. These four or five sutures applied to the lateral uterine segment readily control the slight hemorrhage from the lateral arteries of the utero-ovarian vascular circle. The sutures are subsequently removed. The operation, therefore, consists in the removal of about three-quarters, or two-thirds of the median portion of the uterus, including its cavity, leaving only one-eighth or one-fourth of the lateral border *in situ* on each side. The closer the myometrium is cut away from the endometrium the more and more is its hemorrhage of a capillary nature and more easy to control. The operation saves all the internal genital organs intact, excepting the central portion of the uterus, and by using silver wire for sutures may be done almost without pain or suppuration.

89. **Pruritus Ani.**—Duncan remarks in regard to this condition: that the cause, whatever it may be, whether chronic eczema, herpes, constipation, diabetes, worms, over-mental strain and worry which is a frequent cause, may have to all be looked after to relieve the symptom, and he mentions amongst the direct remedies to be used, local applications of hot water, carbolic acid, lotions, and one that he has never seen mentioned elsewhere, collodion. He says: separate as widely as possible the folds of the skin and mucous membrane and then apply common collodion freely. This will relieve, for a time, all the itching.

91. **Mistakes of the Physician.**—The mistakes here noted by Moots are those made by many of us in adopting the profession, mistakes in regard to personal disposition, pessimism, etc., and he thinks, too, about one-half of the physicians pay too little attention to their dress and toilet and to the condition of their offices. Too many are practically loafers, many are too hasty, and many violate good principles in obstetrics by too early resource to instruments. Other errors are lack of care in examinations, and especially the lack of business methods. Physicians should be charitable and have a brotherly feeling toward other physicians.

93. **The Doctor.**—Kimmell's paper, like the one preceding tells what the doctor should do. He should have sufficient mental caliber in the first place, and should be a more broadly educated man, should be industrious, cheerful, and of high principles.

95.—See abstract in The Journal of January 5, p. 57.

105. **Morphinomania.**—Ahlborn reports a case in which he treated the morphin habit by giving heroin, as it occurred to him that as a morphin derivative with a sedative and stimulating action, it might be of some use. The patient being accustomed to the hypodermic method of using morphin, he put him on hydrochlorid of heroin, giving it in the form of 1/12 gr. tablets, allowing one of these for each ½ gr. of morphin he had been in the habit of taking. As he was consuming about

12 gr. of morphin a day, this allowed him 2 gr. of heroin every twenty-four hours. Strychnin was also kept up and the patient treated for the relief of an existing urinary trouble. The patient declared that he did not need morphin under this treatment; he slept better, and it was continued for about a month, when no craving for the drug being manifested, it was decided to cut down the dose gradually and it was reduced one-half without producing any unfortunate symptoms. The patient had recovered his spirits and had no drug craving whatever. One month later the amount was reduced to about .25 gr. a day, and, in the course of two weeks it was entirely withdrawn, the tonic treatment being pushed. It is now more than seven months since the patient was discharged and he has not returned to his old ways. The second and third cases were treated in the same way. The author claims that in these cases at least it has been a very valuable drug. He claims that the cases cited show that heroin will take the place of morphin without injurious effects, satisfies the craving and allows the withdrawal of the drug without the bad effects commonly observed.

117. **Ligation of Ureter.**—Kibbe reviews the opinions of authorities in regard to ligation of one ureter, and finds that two general propositions may be deduced: 1. That life is possible in man after ligation of one ureter. 2. Given a local disease of the distal portion of the ureter of considerable extent, without infection in it or the kidney on the other side, where anastomosis is impossible, simple ligation rather than the severer operation of nephrectomy would seem worthy of consideration.

127. **X-Ray Burns.**—Florentine reviews the question of *x*-ray burns and the precautions which have been recommended. The grounded screen is, he thinks, more or less effective, though not absolutely so, and he suggests the possibility of individual idiosyncrasy as affecting the incidence of these accidents. He suggests that there is no known means of absolute protection, but he gives a list of those which have shown a tendency to help the situation: 1. Short exposures, which are perfectly satisfactory with our present approved apparatus and materially reduce the danger. 2. Distance between the active tube and part to be exposed; at least eight inches with the improved apparatus is equally effective and adds sharpness and detail to the negative. 3. Always avoid exposing the part frequently unless the rays are used for their therapeutic results, then the tube should be regulated according to the best knowledge of the effect to be produced. 4. Where much density is to be overcome and exposure necessarily long, use the protective screen impervious to the dangerous rays. 5. The vacuum should be as high as required to give the best results with the shortest exposure. He also claims that injuries were more frequent immediately following the earlier use of the *x*-ray than now, and by using the precautions mentioned and with our improved apparatus these may be almost entirely eliminated. It makes no difference whether a Ruhmkorff coil, a Tesla coil, or a static machine is used, their improper use invites danger. There is a needless alarm among the laity and we should deal with our patients honestly and wage an active war against fake institutions, and quacks and characters that swindle.

British Medical Journal, February 16.

The Heart-Index Interval in Aortic Regurgitation. Paul M. Chapman.—The prolonged interval in aortic insufficiency has been studied by Chapman, who accounts for it by the slow propagation of the pulse wave in these cases. Increased arterial tension tends to obliterate this delay, while diminished arterial tension makes it more manifest. The hypertrophied heart also contracts more slowly, owing to the delay of propagation of the nervous impulses through the enlarged muscles; this he considers a new point noticed by himself. He discusses the question at length, giving evidences for these conclusions, and believes that they are firmly established.

Effects of Muscular Exertion, Sudden and Prolonged, in Young Adolescents. W. Collier.—In attempting to ascertain the effects of severe muscular exertion, we have, Collier remarks, to study first the physiologic changes set up by moderate exertion. The effects of exercise on the two most important organs, the heart and lungs, are first noticed. The first effect of exercise is to increase the force of the heart's beat and cause an active congestion, which swells the pulmonary capillaries and diminishes the air space. As the muscular effort continues, it increases the amount of CO_2 that is thrown into the blood, stimulating the respiratory center of the brain; inspiration becomes deeper and more frequent and more air is thrown into the air cells, impeding the circulation in the pulmonary capillaries, and the heart beats more and more quickly, but each ventricular systole is less vigorous and we have passive congestion of the lungs, which is a marked obstacle to the elimination of CO_2. This can not be done beyond a certain point, as too much CO_2 in the blood brings about the cessation of all effort. We have here, therefore, physiologic emphysema. In athletes who have been through years of athletic competitions, we often find the following signs of physiologic emphysema: 1. Absence of apex-beat either on inspection or palpation, while at rest. 2. Absence of all superficial cardiac dulness on account of the large emphysematous lung covering the heart and separating it from the thoracic wall. 3. A hyperresonant note above the clavicles and above the sternum. If the cause of this is repeated too often, or kept up too long, it is quite possible that it may become converted into a pathologic condition, leading in later life to the same consequences as we have from old-standing bronchitis and chronic asthma. Another effect is to throw a great strain on the right side of the heart, since passive pulmonary congestion implies overdistention of the right ventricle. The author calls attention to a form of heart strain not uncommon among girls and young women, who do much running up and down stairs. It is generally associated with a certain amount of anemia, and probably due to atonic conditions of the heart muscle induced by impoverished blood. The most prominent symptom is breathlessness on exertion and great frequency and tumultuous action of the heart. Girls about the ages of rapid growth with marked functional changes may have minor forms of dilatation of the right side of the heart, especially liable to occur with overexertion. The effect of severe muscular exertion on the left side of the heart is to produce a physiologic hypertrophy, and if this is overdone there is danger in it. Insomnia is not an uncommon troublesome symptom with this form of physiologic hypertrophy. Collier advises that boys in schools should be examined before being allowed to take part in athletic exercises, and especially in the adolescent periods and when they are growing rapidly. Cases of severe and sudden breakdown in well-fed boys and college students are rare. The danger lies in the future, some twenty years or more after. He notes the prophylaxis, advising physical examinations of school boys and students, but says that the danger is less in this class than with the lower middle classes outside of public schools. In concluding his paper he remarks on the physical standard of the army being too high. Many men are rejected on account of insufficient weight or chest measurement. A long, narrow chest may have equal lung capacity with the broad one, but the tape only measures the horizontal diameter; it takes no cognizance of the vertical. Intermittent albuminuria is mentioned, and Collier explains it on the ground of some defect in the walls of the blood-vessels of the kidney. The condition often gives rise to no special trouble, and the treatment for it seems to do very little good.

Cases of Adult General Paralysis with Congenital Syphilis. R. Percy Smith.—The possibility of general paralysis in adults being due to the same cause as when it occurs in young persons suffering from congenital syphilis is noticed by Smith, who reports two cases: 1. The full account of a patient of Dr. Mott's, mentioned by him in his Croonian lecture on degeneration of the neuron as possibly of this nature. 2. The other one was a personal observation of his own. In both cases they were women of 28 and 24 years respectively. There was no suspicion of acquired syphilis, but little doubt as to paternal. The paretic symptoms were characteristic.

Wind Exposure and Phthisis. Charles A. Davies.—The paper by Gordon, of Exeter, in which he attributed the great frequency of phthisis to wind exposure in certain English districts, is the text of Davies' article. He gives the facts as regards the Isle of Man, showing that the conditions there do not bear out Gordon's views. In fact, if the wind theory is true, the regions in that island which give the least rate of phthisis should give the highest, and he can not find anything that supports the theory that strong winds are accountable for the peculiar distribution of disease in the Isle of Man, whatever may be the cause elsewhere. Phthisis among women and children who shut themselves up in small cabins can not properly be attributed to wind exposure, though it is done to escape the inclemency of the winds; it is due to vitiated atmosphere.

Thyroid Extract as a Remedy, with Illustrative Cases. P. Blaikie Smith.—The author reports several cases where thyroid extract was used for conditions other than myxedema with remarkably favorable results. One was a case of extensive carcinoma, in which many of the nodules disappeared and there was a general temporary improvement. In other similar cases, however, the same treatment seemed to be ineffective. Another case was that of a child three years old, suffering from edema and bullæ, with constant relapses. The case proved refractory to all radical treatment, but thyroid extract in 1/3 gr. doses two or three times a day, given as a last resort, was extremely effective. The third case was one of obesity associated with Bright's disease, in which the effects were perhaps less unusual, but were very striking.

The Lancet, February 16.

Remarks on Agglutination by Plague Blood. E. Klein.—Various observers have noticed that the blood of persons convalescent from plague possesses the power of agglutinating plague bacilli in cultures. Klein has investigated the case and finds certain difficulties. In the first place good emulsion is hard to make. The plague bacilli are naturally aggregated in cultures and a uniform distribution of micobes is not as easy to bring about as with some other organisms. He tried to make a workable emulsion from gelatin surface cultures, by distributing the gelatin growth in physiologic salt solution, and he finally succeeded. The emulsion in bouillon, as generally used for other bacilli, is not applicable since it is not itself without effect in causing agglutination of plague bacilli. Experiments with the salt solution with the blood of rats that had been injected with Haffkine's prophylactic, and later with living plague cultures, showed a very marked agglutination in ten minutes, and control experiments with normal human blood and normal mouse's blood showed no such effects.

Deutsche Med. Wochenschrift (Leipsic), February 7 and 14.

Bacteriology of Articular Rheumatism. F. Meyer.—Two years of efforts to cultivate a micro-organism from the blood or joint effusion in cases of articular rheumatism resulted negatively. But when mucus taken from the tonsils was employed no difficulty was experienced in cultivating a peculiar, delicate streptococcus which induced a seropurulent, usually sterile, joint affection in animals, not leading to sepsis. The lesions showed a special affinity for the serous membranes and the endocardium.

Bactericidal Power of Electric Light. H. Strebel.—A series of tests and experiments is described which, the writer states, formed the first scientific demonstration that the bactericidal power of light is exclusively the property of the short-wave rays beyond the violet—the ultraviolet. He describes an improved technique for radiotherapy, enhancing the bactericidal power of the light by using, instead of the ordinary carbon arc-light, electrodes made of a combination of aluminum, cadmium, zinc and carbon, and cooling the compressorium with a stream of compressed air, determining the power of the light not by the visible appearance, but by its action on aristo paper.

February 14.

Operating in the First Moments of Ether Inhalation. P. Sudeck.—In about two hundred operations at Hamburg. the surgeon began his work after the first or second deep inhalation of ether by the patient, without waiting for absolute narcosis. It was found that complete unconsciousness accompanies the first inhalations, if the patient's attention is diverted from the operation, if the instruments are concealed, etc. Brief operations can thus be concluded with the minimum of ether, and before the patient reaches the stage of agitation. Kuemmell has thus amputated a leg or arm in feeble, elderly persons, with no intimation on their part that they experienced pain. Occasionally the patients say that they feel the surgeon's touch, but no pain. Harless is quoted as saying that the ether "may reach the brain through the lamina cribrosa at the first whiffs, as a brief anesthesia with unconsciousness is observed at this time, which is sufficient for a rapid operation." During the extirpation of glands in the axilla the raised abducted arm showed no voluntary nor reflex tendency to adduction, which testifies to the effectiveness of the insensibility induced by the first whiffs of ether.

Operative Treatment of Pulmonary Tuberculosis. H. Sarfert.—Experiences with 150 cadavers showed that the best route for surgical intervention on the lung is by resection of the second rib, detaching the pleura with the hand as one cuts the pages of a journal, freeing the lung without opening the pleura, and after locating the lesion by palpation, opening the cavity with the knife or thermo-cautery. No large vessels are encountered and the operation is remarkably simple. It is indicated in case of a single large cavity, with the remainder of the lungs and the large bronchi very little, if any, affected, and no other organs involved. Sarfert thus operated on a woman of 40 and found the conditions exactly as favorable as in the cadaver. Solid adhesions were found after resection of the second rib, and the loss of blood was remarkably slight, both in the wound in the blunt detached lung and in the newly formed layers of connective tissue on lung and pleura. The position and size of the cavity were readily ascertained and it was extensively opened. There was no asphyxia nor dyspnea. The large cavity communicated with a second smaller one: both were easily tamponed. The wide gap left between the apex of the lung and the thorax gradually closed by granulations. Neither the previous hectic fever nor hemoptysis recurred. The wound had closed in three months to a granulating strip 3cm. wide with a crater 3cm. deep. After two months of euphoria the patient succumbed to an attack of pneumonia in the lower lobe of the other lung. The autopsy showed that very few tubercular nodules were scattered over the lung that had been operated on; there were no evidences of the cavities. The apex had become transformed into tough connective tissue, but the remainder of the lung was air-tight.

Muenchener Med. Wochenschrift, January 29.

Clitoris Crises in Tabes. G. Koester.—A case of this rare complication of tabes, of which Pitres has published three cases, is described at length. The clitoris crises correspond to gastric crises and also to the genital disturbances in men during the course of the affection.

Influence of High Temperature on Milk. H. Conradi.—Heating milk above 80 C. produces a permanent chemical or physical change in its constitution beyond that usually recognized. The normal coagulating point of the milk by calcium and similar salts is diminished by 8 to 12 degrees, while the action of rennet is retarded.

Prophylaxis of Venereal Diseases Among Students. W. Scholtz.—The pamphlet warning against the dangers of venereal disease which is now distributed among the students of Germany when they enter the universities, has already commenced to bear fruit, as Scholtz is able to prove by statistics from the clinics, etc.

February 12.

Tendon Transplantation in Case of Paralytic Deformities. E. Kunik.—The remarkable benefits to be derived from this tendon transplantation in cases of old paralytic deformities are [illegible], who states that the number of actually hopeless cases is being gradually reduced. The tendons are lengthened, shortened or transplanted as indicated, but the operation is not undertaken so long as a trace of spontaneous improvement is apparent under massage, baths and electricity. When the condition has been stationary for six to twelve months or the deformity is rapidly increasing, the operation is indicated.

Treatment of Perineuritis of the Sacral Plexus. A. Guttenberg.—The prognosis of this affection is favorable even in elderly persons. General tonic treatment should be supplemented by local massage, the patient in the position allowing easiest access to the affected nerves. The massage should only last a few minutes and should be very gentle, stroking the thickened cords or nodules from the side toward the sacrum, slowly increasing the pressure. The limb is then repeatedly hyperflexed to stretch the sacral nerves and promote absorption. Neurasthenic conditions are benefited usually by wet cold packs, and gentle gymnastics and baths cure the muscular atrophy. In patients with a suspicion of thrombosis and in elderly persons digital massage is substituted by a rectal injection of a pint of tepid water retained for a few minutes, and repeated twice a day. By these means improvement is soon evident. The pains and other disturbances disappear and with them the anemia and concomitant symptoms of irritation of the nervous system. Five cases are described; pains, weakness, trembling of the lower limbs, accompanied by anemia and a palpable "Rosenkranz" swelling or general thickening of the nerve were the most prominent symptoms.

Wiener Klinische Rundschau, February 10.

Thickening of Peripheral Nerves from a Cold. H. Propper.—A case is described of palpable perineuritis in consequence of trauma and two others of peripheral neuritis due to rheumatic influences. In the latter the long saphenous nerve was palpably thickened. Reviewing similar cases in the literature, Propper asserts that peripheral neuritis from a primary cause—catching cold—is of frequent occurrence. The more exposed nerves, such as the facial, cervicobrachial, sciatic and crural nerves and the saphenous are especially sensitive. They are sometimes thickened to twice their normal size. These swellings of the nerves from rheumatic influences may be either unilateral or bilateral. In a few cases the tendon reflexes were exaggerated with these purely peripheral affections.

Wiener Klin. Wochenschrift, February 14.

Mechanical Treatment of Certain Varieties of Vertigo. V. Urbantschitsch.—The dizziness that occurs when one whirls the body on the vertical axis can be overcome by practice. In the same way one can become accustomed to the dizziness caused by swinging the head around, etc. For two years the writer has been applying this principle to the treatment of vertigo, with remarkable success. He describes two typical cases consecutive to an operation for the cure of caries of the temporal bone, in which the horizontal semicircular canal had probably been injured. In one the vertigo after ten weeks was still so intense that it was impossible for the patient to ascend stairs or to walk alone. Systematic exercises, swinging the head around, repeated several times a day, stopping when distinct dizziness appeared and waiting for it to subside improved the patient so much in two weeks that he was able to balance his one-wheeled, heavy scissors-grinding machine as before without trouble.

St. Petersburg Med. Wochenschrift, January 26.

Carcinoma Under Thirty-two. W. Vierhuff.—Five patients between 28 and 32 years of age have been in Vierhuff's charge during the last few years, all with carcinoma of the stomach or intestines. The first and most constant symptom was good appetite with repugnance to food. At every attempt to eat nausea and discomfort in the stomach were experienced. Weakness and emaciation were frequently noted before the gastric contents showed abnormal conditions. Intermittent fever was also observed, appearing with symptoms simulating malaria. Kusick and Treyman have each observed three cases of malignant neoplasms. In the latter's cases the age was between 26 and 29, and all were located at the portio. In spite of apparently favorable conditions the cases terminated fatally in one to nine months to two and one-half years. Three cases of carcinoma of the rectum in still younger girls were also rapidly fatal.

Vratch (St. Petersburg), XXI, 48, 51 and 52, 1900.

Massage-Plaster Open Splint for Fractures. Piletzky.—The plaster splint used by Piletzky for simple fractures is made of a bag of gauze filled with plaster mixed with carded flax. An opening is left over the region of the fracture and through it the spot is massaged, commencing the very first day. After eight to twelve days the splint is removed for massage of the entire limb and passive movements. At the end of two weeks active movements are commenced. The massage is done twice a day for ten to fifteen minutes. Nine cases are described, demonstrating the exceptionally rapid recovery, the patients walking in twelve to thirty-three days after fracture of a bone in the leg and in twenty to twenty-seven days after fracture of the femur.

Semana Medica (Buenos Ayres), December 20.

Sodium Hyposulphite in Bubonic Plague. J. Penna.—Six patients severely ill with bubonic plague were treated by subcutaneous injections, in the vicinity of the infarcts, of 1 gm. of sodium hyposulphite to the cubic centimeter, every three hours. The bubo became gangrenous in two cases, one of them fatal. The remainder recovered. Penna's previous experiences with this treatment in twenty cases were described in The Journal of January 19, p. 220.

Bulletin de l'Acad. de Med. (Paris), January 29 and February 5.

Sterilization of Cocain. Reclus.—One gram of cocain hydrochlorate in 100 grams of distilled water is distributed in small vials which are plugged with cotton and placed in a water-bath. The temperature is gradually raised to 100 C. and the boiling continued for half an hour. This method has proved more satisfactory than that of Tyndall's in three years' experience. The cocain remains intact and retains all its properties, the light-rotating power is not altered nor is the anesthetic action modified.

February 5.

Glycosuria and Diabetes of Dyspeptic Origin. A. Robin.—These conditions are frequently misunderstood and erroneously treated. Dyspeptic glycosuria is characterized by temporary, irregular, comparatively insignificant glycosuria during digestion only. It is frequently accompanied by transient albuminuria and always by an exaggeration of the general nutritive interchanges, nitrogenous and nervous. This glycosuria is noted in dyspeptics with a good or even an exaggerated appetite, with the stomach distended, with hyperchlorhydria, and the liver large and more or less tender. Accessory symptoms dependent on the primary cause are neurasthenia, vertigo, phosphatic, milky urine, dermatoses, cardiac phenomena and profuse sweats. It may develop into actual diabetes, but yields usually to suitable treatment of the hypersthenic dyspepsia. It is probably due to two causes: The exaggerated reflex excitation of the duodenum, etc., by the passage of a hyperacid chyme, stimulating the biliary function by reflex action, and the direct excitation of the liver cells by the elaborated or transformed glycogen. Dyspeptic glycosuria thus differs completely from the alimentary variety and from latent diabetes. It is the result of excitation while the others are the result of insufficiency. But the frequently repeated excitation may in time lead to genuine diabetes—that is, continuous excitation. Dyspepsia may be the prime cause in many cases of diabetes, and this explains the gravity of dyspepsia in a diabetic. The treatment is merely that of ordinary hypersthenic dyspepsia. In mild cases sedative medication is sufficient; in others, an exclusive milk diet may be required. If the glycosuria persists, the functional activity of the liver must be modified with antipyrin combined with sodium bicarbonate, or sodium arseniate and potassium arsenite, or lithium carbonate, codein, opium, belladonna, valerian, etc. One or two doses of 50 to 75 cg. of antipyrin combined with 50 cg. of sodium bicarbonate or the judicious use of sodium arseniate are usually sufficient. In case of dyspeptic diabetes or considerable glycosuria, the activity of the liver must be reduced at once, and the following three-day course of treatment instituted: First, the diabetic regime, suppressing all raw and acid foods. One and one-half hours before breakfast and dinner a powder of 50 cg. to 1 gm. of antipyrin and 50 to 75 cg. of sodium bicarbonate in seltzer water should be taken and during meals no beverage but Vichy water from the the Lardy spring. After meals one of twelve powders containing 4 gm. each of calcined magnesia and sodium bicarbonate mixed with 6 gm. of prepared chalk should be given. If gastric crises or pyrosis occur, or sensations of burning, constriction or dragging-down are felt in the epigastrium in the intervals between meals, one of ten powders should be taken containing 15 gm. of calcined magnesia, 7 gm. of bismuth subnitrate, 7 gm. of prepared chalk, 5 cg. of codein and 10 gm. of sodium bicarbonate. As soon as the sugar disappears from the urine, this medication can be suspended and treatment addressed solely to the hyperasthenic dyspepsia be inaugurated, commencing with a strict milk diet. If the sugar reappears in large amounts the antipyrin treatment must be resumed, but if it is minimal, 15 cg. of lithium carbonate are usually sufficient, taken before breakfast and at night, dissolved in a spoonful of water, to which is added a tablespoonful of a mixture of 5 cg. sodium arseniate in 300 gm. of distilled water. If the irritating action of the arsenic is feared, rectal injection of 5 c.c. of a mixture of 8 gm. of Fowler's solution in 92 gm. of distilled water may be substituted. In old-established cases the treatment of the diabetes and of the dyspepsia should alternate as the symptoms of each predominate. Starches and sugar should be avoided.

Bulletin de la Soc. des Hop. (Paris), January 24 and 31.

Cellular Elements in Pathologic Cerebrospinal Fluid.—Communications from Widal, Sicard, Monod and others announce that the cerebrospinal fluid contains cellular elements, lymphocytes predominating, in chronic affections in which the meninges are involved, and this is especially noticeable in tubercular meningitis, tabes, general paralysis and meningomyelitis. This symptom, indicating an alteration in the arachnopia mater, may in certain cases clear up the diagnosis between a central and a peripheral lesion, or confirm a dubious diagnosis of tabes or general paralysis. The cellular elements were not found in any of the cases of hemiplegia or peripheral neuritis examined, nor in alcoholics nor hysterics. In acute processes such as cerebrospinal meningitis, polynuclear elements predominated, indicating more extreme processes of defense. Lymphocytosis and the causal meningitis have been observed in 11 cases of general paralysis and 7 of tabes, none negative. Meningitis had been noted previously in 11 cases of paralysis and 9 of tabes, but the fluid was not examined.

Presse Medicale (Paris), February 2.

Hygiene of the Ear. LERMOYEZ.—Among the other measures recommended are mentholized olive-oil, 1 to 50, which is stated to be specific for coryza in children. It sterilizes and renders the nasal passages permeable, with no possible danger to the ear as from other substances. The child lies on his back and a few drops of the oil are instilled from a syringe or dropper three times a day. Intense nervous deafness may be caused by reflex action of worms in the intestines. The hearing is also liable to suffer, Lermoyez adds, from prolonged mental exertion in the quiet of the study. The ear hears, but it is the brain that listens, and if the latter is overworked, the hearing suffers.

To Banish the Bacilli from the Mouth and Throat After Diphtheria. MAETHER.—The conclusions of the writer's tests are that peroxid of hydrogen and ammonium carbonate are effective gargles for eradicating lurking bacilli after diphtheria. Ammonium carbonate has the advantage of dissolving the mucous secretions and thus allowing the disinfectant access to the bacteria. Maether recommends a combination of the two, gargling first with a 1 per cent. solution of ammonium carbonate and then with a 10 per cent. solution of commercial peroxid of hydrogen. If bacilli still lurk in the deep crevices of the tonsils, they must be mechanically dislodged with a fine sound.

Revue de Chirurgie (Paris), February.

Ligature of the Abdominal Aorta. P. TILLAUX AND P. RICHE.—The abdominal aorta has been ligated in thirteen cases, with a mortality of 100 per cent. according to the literature. Experiments in this line on animals were reported as early as 1667, and have been numerous during the last century. They prove that ligature of the abdominal aorta is not necessarily fatal, except perhaps in the rabbit. It is followed by anemia and paralysis in the hind legs, but not by gangrene nor permanent paraplegia. In man, the gravity of obliteration of the aorta varies with the cause and extent. It is unsuspected when congenital; but may prove rapidly fatal when of embolic origin. Consecutive gangrene and paralytic phenomena have been observed, the latter ranging from intermittent limping—claudication—to complete paraplegia. In every case of gangrene or persisting paralysis, the obliteration was not restricted to the aorta. In 11 of the 13 clinical cases the aorta was ligated on account of non-sacculated aneurysm, and twice on account of hemorrhage. In 7 the ligature was applied through peritoneum, in 6 by the retro-peritoneal route. Gangrene did not occur in any of the cases; the symptoms of cerebral congestion noted were rare and insignificant and the paralytic phenomena were inconstant, variable and transient. None of the deaths were directly attributable to the operation. Indications for ligature of the abdominal aorta are extremely rare, but study of the cases on record shows that the surgeon need not hesitate when he encounters the indications, as the obliteration of a sound aorta entails merely slight transient disturbances in the circulation, incapable of compromising the vitality of the lower limbs, and transient paraplegic disturbances. The details of all the cases are given, continued through several numbers of the *Revue*.

Study of Osteomalacia. G. GAYET AND L. M. BONNET.—The conclusions of this comprehensive study of osteomalacia are that the affection is due to a disturbance in the nutrition of the bones, consisting in an insufficient supply of lime salts and leading to the softening of the skeleton. This disturbance in nutrition may be local or general. Local osteomalacia is observed after traumatisms, infections of the bones and also in certain nervous affections. The lesions are of the same character in the local and in the general forms, but with variations not explainable by the apparent etiology, the clinical variety nor the extent of the generalization of the affection. There is nothing specific in the pathogenesis, but there are predisposing causes in age, sex, climate, etc. The actual determining cause is still obscure: but the facts that have been observed point to disturbances in the nervous system as the chief factor.

Protection of Raw Surfaces in Laparotomies. E. QUENU AND JUDET.—Since 1895, Quenu has made a practice of covering with serous membrane all the raw surfaces left after a laparotomy. By this means normal conditions are re-established and exudation is prevented. In case of vegetating cysts of the ovaries the entire pelvic cavity is made extraperitoneal by suturing the vesical peritoneum to the sigmoid loop and the peritoneum over the promontory. The method is particularly advantageous in case of salpingitis, supplemented by abdominal drainage if necessary. Traction on the organs brought together by the suture must be carefully avoided. The patients complain less of colic, and drainage can be discontinued in two to four days. Micturition and defecation have never been affected. Only 5 deaths have occurred in Quenu's last 129 operations for salpingitis, and they include one case of tubercular peritonitis, 3 from extension of the preceding pelvi-peritonitis, one from generalization of tubercular peritonitis and one from cachexia due to a renal complication. Tardy digestive disturbances and abdominal pains are less frequent than in the past, which testifies to more perfect intestinal functioning and the absence of adhesions. Post-operative occlusion of the intestines occurred in only one case, in which cure was easily effected by a secondary operation. The writer concludes that with peritonization recoveries are not only more frequent but they are more perfect and permanent.

Surgical Complications of Typhoid Fever. E. LOISON.—In the personal case described, the small intestine became perforated on the sixteenth day of typhoid fever, the patient being a young soldier. Loison operated fifteen hours later and the patient recovered. Keen's statistics gave the proportion of recoveries after surgical intervention on account of typhoid perforation as 19.3 per cent.; Platt, 20.3 per cent.; Mauger in 1900, 23.3 per cent., and Loison has now collected 16 successfully operated cases with 74 failures, a proportion of 21.6 per cent. The best results have been attained during the first twenty-four hours after perforation or commencement of the peritonitis, but the condition of the patient is the best guide. Subsidence of the primal peritoneal shock must be awaited. In the 16 successful cases, operation was made between the sixth and twelfth hour in 6; between the twelfth and twenty-fourth in 4, at the twenty-sixth in 1 and at the sixtieth hour in another. In Legueu's case a large perforation was found near the ileo-cecal valve. The tissues were too friable for suturing and the place was patched with a graft of omentum. The perforation occurred on the twentieth day and the operation was performed six hours later. The patient, a youth of 15, recovered with a stercoral fistula which healed spontaneously in three weeks. Loison prefers a median incision as more convenient for locating the perforation. If in the small intestine, it is usually near the ileo-cecal valve. Transverse suture is preferable to longitudinal, judging from the results published. If the intestine is very friable it can possibly be sutured to the abdominal wound. Total resection of the loop may sometimes be necessary, but the bad results after extensive resection discourage further attempts in this line. There are only five cases on record in which death occurred in consequence of new perforations after the operation.

Semaine Medicale (Paris), January 30.

The Adequate-Dosage Method Applied to Various Nervous Affections. Gilles de la Tourette.—The Journal described the details of this method of administering the bromids in epilepsy, Oct. 27, 1900, p. 1120. The results obtained with it have surpassed the most sanguine expectations and the principle is now being applied to other diseases. The method is based on the determination of the actual individual tolerance in each patient, by watching for certain physical signs and symptoms, peculiar to each drug, indicating the *approach* of intolerance. The individual adequate dose thus established is maintained for a length of time sufficient to completely abolish the cortico-motor hyperexcitability of the brain in epilepsy, and with it all tendency to seizures. The three-week period plan is followed, increasing by 1 gm. a week until the proper dose is ascertained, then maintaining it at this point in three-week periods, as for instance: 3, 4, 5; 3, 4, 5; 3, 4, 5 gm. and so on. It is then gradually diminished to final suppression. In this point there is a slight modification of the original method as first published. Other nervous diseases successfully treated in this way have been severe, associated forms of migraine, Menière's vertigo, grippal neuralgia and tic-douloureux. The results emphasize the exceptional benefits to be derived from this "proper-dose method." In a typical case of ophthalmoplegic migraine in a man of 35, for example, the paroxysms recurring frequently, sometimes every week and lasting three or four days, there has been no recurrence since a course of treatment last September. The adequate dose of bromid in this case was found to be 7, 8 and 9; 7, 8, and 9 gm., determined by the pupil sign and general manifestations at the close of the first third week. The complete course for this severe migraine requires about eight to twelve months. Quinin is the specific in Menière's disease.

Centralblatt f. Chirurgie (Leipsic), February 2 and 9.

Direct Suture of the Resected Ureter. A. V. Gubaroff. In an operation which required resection of 3 cm. of the ureter, the ends were sutured together at once, a small slit downward from the top in the peripheral end allowing it to be fitted over the central end. A stitch at the back and at each side held the parts in position and the slit was sutured as the final step. The patient died thirty-one days later from amyloid degeneration. The ureter was found practically normal with scarcely a trace of the defect and invagination. Absorbable suture material was used, and the stitches were taken lengthwise.

February 9.

Treatment of Injury of the Internal Soft Parts of the Knee. C. Lauenstein.—The writer has found that recovery was more prompt and satisfactory when the extravasated blood was evacuated by puncture, followed by immobilization of the joint for a few weeks. He has found it possible to determine the existence of rupture of the capsular ligament by inserting a bougie through the puncture-opening.

Muscular Transplantation for Contraction of Knee. C. Bruns.—In three cases of recurrent contraction of the knee after an old, healed infection, Bruns transplanted the tendon of the biceps into the tendon of the quadriceps. The results have been very satisfactory, the contraction and pain are completely abolished and the patients regain normal use of the limb. In one the contraction was consecutive to gonorrheal gonitis, the patient 24 years of age; in another to fungus of the knee in a boy, and in a third, a woman who had been confined to her bed for years on account of the extreme painful contraction of both knees from articular rheumatism. This patient has not been allowed to get up yet, but the knees are now normal.

Queries and Minor Notes.

PHYSICIANS AND THE AUTOMOBILE.

Lead, S. D., Feb. 22, 1901.

To the Editor:—In considering the purchase of an automobile, will you advise me which one or make is most practicable for a physician's use? Is an electric vehicle better than one of gasoline power? H. S. J.

Ans.—We are unable to advise our correspondent. While the electric automobile seems to us to be too limited in its radius of action for general country practice, it has many advocates, but the gasoline motor seems to be the most popular at the present time. The question of automobiles is an important one and The Journal will be glad to hear from its correspondents in regard to the matter, especially from those who have had experience in their use. Many are now using the automobile instead of the horse, and it would be interesting to those who are thinking of adopting this mode of conveyance if physicians now using them would give their experience for publication in these columns.

LABORATORY INOCULATION.

Iowa City, Iowa, Feb. 14, 1901.

To the Editor:—Will you inform me whether there have occurred, to your knowledge, any cases of accidental inoculation with diphtheria in the laboratory while working with cultures, and references? L. F. G.

Ans.—Yes, such accidents have occurred, and dangerous attacks of diphtheria have been the result. Fortunately they are rare and appear to depend on purely accidental conditions. We can not give definite references.

MALARIA DATA

Yoakum, Texas, Feb. 13, 1901.

To the Editor:—In The Journal of the 9th, I note reference to a paper by Wells on malaria, also by Edwards, Preble and Favill, and will be very much obliged if you will give me the name and address of the publishers of each of the papers. W. S.

Ans.—The articles were published in the *Chicago Medical Recorder* for January. Address Medical Recorder Publishing Co., Pullman Bldg., Chicago.

PRACTICE IN ILLINOIS.

Columbia, Mo., Feb. 18, 1901.

To the Editor:—What is the law governing practitioners in Illinois? If one holding a diploma has to go before the state board, give address of one of the members.

Ans.—This question was answered in The Journal of February 16, to which the correspondent is referred. The secretary of the State Board of Health is Dr. J. A. Egan, Springfield, Ill.

PRACTICE IN KENTUCKY.

Kansas City, Mo., Feb. 26, 1901.

To the Editor:—Kindly give the requirements of the State Board of Health of Kentucky regulating the practice of medicine in that state, also name and address of secretary of the board. R. J. S.

Ans.—A diploma from a reputable medical college, endorsed as such by the State Board of Health; registration with the county clerk after receiving certificates from the board is essential. Dr. J. N. McCormack, Bowling Green, Ky., is secretary of the State Board of Health.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

SYPHILIS OF CHILDREN IN EVERY-DAY PRACTICE. By George Carpenter M.D., Lond., Physician to the Evelina Hospital for Sick Children, London. Cloth. Pp. 110. Price, $1.25. New York: Wm. Wood & Co. 1901.

OBSTETRIC AND GYNECOLOGIC TEACHING. By Edward P. Davis, A.M., M.D., Professor of Obstetrics in the Jefferson Medical College, Philadelphia. Illustrated. Pp. 402. Price, $1.75. Philadelphia and London: W. B. Saunders & Co. 1901.

AN INTRODUCTION TO PHYSIOLOGY. By William T. Porter, M.D., Associate Professor of Physiology in the Harvard Medical School. Cloth. Pp. 314. Price, $2.50. Cambridge, Mass.: The University Press. 1901.

THE HISTORY OF ANCIENT GYNECOLOGY. By W. J. Stewart McKay, M.D., M.Ch., B.Sc., Senior Surgeon to the Lewisham Hospital for Women and Children, Sydney. Cloth. Pp. 302. Price, $3.00. New York: Wm. Wood & Co. 1901.

TRANSACTIONS OF THE LUZERNE COUNTY MEDICAL SOCIETY For the Year Ending Dec. 31, 1900. Volume viii. Paper. Pp. 220 Wilkes-Barre, Pa.: E. B. Yordy Co. 1900.

INTERNATIONAL CLINICS. A Quarterly of Clinical Lectures and [illegible] ticles on Medicine, Neurology, Surgery, [illegible] Pediatrics, Pathc [illegible] Dis- [illegible] Nose and Throat, [illegible] Interest to Students and Practitioners. By [illegible] the Medical Profession Throughout the World [illegible] W. Cattell, A.M., [illegible] B. Murphy, M.D., Chicago: Alexander D. [illegible] H. C. Wood, M.D., Philadelphia: T. [illegible] E. Landolt, M.D., Paris: Thomas G. M [illegible] Charles H. Reed, M.D., Philadelphia: [illegible] Harold, M.D., London. With Regular [illegible] London, Paris, Leipsic and Vienna. Vol [illegible] Cloth. Pp. 312. Price, $2.00. Philad [illegible] 1901.

THE RETROSPECT OF MEDICINE. A Half-Yearly Journal Containing a Retrospective View of Every Discovery and Practical Improvement in the Medical Sciences. Edited by James Braithwaite, M.D., Lond., Consulting Obstetric Physician and Surgeon to the Leeds General Infirmary, and E. F. Trevelyan, M.D., Lond., B.Sc., M.R.C.P., Assistant Physician to the Leeds General Infirmary. Volume 122. July-December, 1900. Issued January, 1901. Cloth. Pp. 442. Price, $1.50. London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd. Edinburgh: [illegible] Dublin: Hodges, Figgis & Co., and Fannin & Co. [illegible]

A SYSTEM OF PRACTICAL THERAPEUTICS. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica [illegible] cond Edition, Re- [illegible] Therapeutic Con- [illegible] sures Other Than [illegible] and Diseases of [illegible] Price, $5.00 net. [illegible] 1901.

REPORT OF THE COMMITTEE ON THE PROTECTION OF NORTH AMERICAN BIRDS for the year 1900. By Witmer Stone: and Results of Special Protection to Gulls and Terns Obtained Through the Thayer Fund. By William Dutcher. Paper. Pp. 104. Extracted from "The Auk," January, 1901.

FIFTH REPORT OF THE COLORADO STATE BOARD OF HEALTH. Covering the Period from Nov. 15, 1894, to Nov. 15, 1900. G. E Tyler, M.D., Denver, Colo. Cloth. Pp. 223. Denver, Colo.: Smith-Br[illegible] 1900.

[illegible] Their Pathology and Treatment. By W. Ro[illegible] of the Royal College of Surgeons. Cloth Pp [illegible] et. New York: William Wood & Co. 1901.

THE JOHNS HOPKINS HOSPITAL REPORTS. Vol. viii. Paper. Pp. 397. Baltimore, Md.: The Johns Hopkins Press. 1900.

TRANSACTIONS OF THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION. Twenty-sixth Annual Session held at Asheville, N. C., Oct. 9, 10 and 11, 1900. Vol. ii. Cloth. Pp. 475. Printed for the Association. 1900.

DISEASES OF THE ANUS AND RECTUM. By D. H. Goodsall, F.R.C.S. (Eng.), Senior Surgeon (late house surgeon) to St. Mark's Hospital for Fistula and Other Diseases of the Rectum, and W. Ernest Miles, F.R.C.S. (Eng.), Surgeon (out-patients) to the Gordon Hospital for Diseases of the Rectum. In two Parts (illustrated). Part 1. Cloth. Pp. 311. Price, $2.50. London, New York and Bombay: Longmans, Green & Co. 1900.

FIFTH ANNUAL REPORT OF THE BOARD OF MANAGERS OF THE SPRINGFIELD STATE HOSPITAL OF THE STATE OF MARYLAND, Sykesville, Md. To His Excellency the Governor of Maryland. October 1, 1900. Paper. Pp. 38. Baltimore: Sun Book and Job Printing Office. 1901.

REPORT OF THE COMMISSION OF EDUCATION for the Year 1898-99. Vol. 2. Cloth. Pp. 1269. Washington: Government Printing Office. 1900.

New Patents.

Patents of February 5 and 12 of interest to physicians:

667,357. Massage device. August Andreae. Frankfort-on-the-Main, Germany.

667,358. Manufacturing acetic acid. Johann Behrens, Bremen, Germany.

667,182. Druggists' label case or cabinet. Wm. W. Billingslea, Macon, Ga.

667,487. Vaporizer. Frank P. Boland, Providence, R. I.

667,491. Atomizer. Oram H. Brigham, Chatsworth, Ill.

667,621. Obstetrical device. Hannah C. Fleming, Falls City, Neb.

667,518. Capsuling machine. Eli D. Harrington, Westfield, N. Y.

667,447. Bust developer. Harry L. Miller, Chicago, Ill.

667,260. Foot-rest for invalid-beds. Ellen F. Stetson, Boston, Mass.

667,469. Apparatus for perfuming or fumigating rooms. John W. Tighe, Exeter, England.

667,481. Respiratory mask or helmet. Charles H. Wood, Trenton, N. J.

34,024. Design; box for hypodermic needles. Fairleigh S. Dickinson, Bayonne, N. J.

34,042. Design; bed pan. Daniel Hogan, New York, N. Y.

667,759. Nitrocellulose, or similar substance, and making same. Da[illegible] ore, Md.

[illegible] ir. Charles F. Davidson, Canton, Ohio.

[illegible] ra De Puy, Warsaw, Ind.

[illegible] Samuel Guthrie, San Francisco, Cal.

[illegible] arles W. McDade, Faribault, Minn.

[illegible] and fumigating apparatus. John H. Se[illegible]

667,961. Medicinal vaporizer. Charles B. Tefft, Utica, N. Y.

34,057. Design; strand-supporting card for fumigators. John W. Castle, Leominster, Mass.

Copies of above patents may be obtained for 10 cents each by addressing John A. Saul, Solicitor of Patents, Fendall Building, Washington, D. C.

Change of Address.

J. P. Price, Medical College, Memphis, Tenn., to Westbrook, Ark.

Nina D. Polson, 676 Jackson Blvd., to 5429 Washington Ave., Chicago, Ill.

Frank Rattan, Antioch, Cal., to Martinez, Cal.

J. J. Ross, Louisville, Ky., to Meshack, Ky.

R. A. Stewart, Dorrance, Kan., to Idana, Kan.

J. E. Thompson, La Grande St., Pittston, Pa., to Taylor, Pa.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Feb. 14 to 20, 1901, inclusive:

George W. Adair, major and surgeon, U. S. A., from Fort Sheridan, Ill., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Bailey K. Ashford, lieutenant and asst.-surgeon, U. S. A., to accompany recruits from Fort Slocum, N. Y., to the Presidio of San Francisco, Cal., and return to his proper station.

Dallas Bache, colonel and asst.-surgeon-general, U. S. A., leave of absence on account of sickness.

Guy G. Bailey, acting asst.-surgeon, leave of absence extended.

Charles M. Gandy, captain and asst.-surgeon, U. S. A., from Fort Slocum, N. Y., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

John J. Gilhuley, acting asst.-surgeon, from Bridgeport, Conn., to temporary duty in the Department of the East.

Charles R. Greenleaf, colonel and asst. surgeon-general, U. S. A., from duty in the Division of the Philippines, to take effect June 1, 1901, then to proceed to San Francisco, Cal., for duty as chief surgeon.

Frederick C. Jackson, acting asst.-surgeon, now in San Francisco, Cal., to temporary duty in the Department of California.

William P. Kendall, major and surgeon, Vols., from further duty in the Division of the Philippines to duty at Fort Slocum, N. Y.

John S. Marshall, dental surgeon, U. S. A., from Washington, D. C., to Philadelphia, Pa., on official business.

Edward B. Moseley, major and surgeon, U. S. A., from the Division of the Philippines to duty at Fort Sheridan, Ill.

Robert T. Oliver, dental surgeon, from Washington, D. C., to Philadelphia, Pa., on official business.

George H. Penrose, major and surgeon, Vols., to temporary duty in the Department of California.

Walter Reed, major and surgeon, U. S. A., member of a board convened at the Army Medical Museum, Washington, D. C., to examine candidates for appointment in the Medical Department of the army.

Navy Changes.

Changes in the Medical Corps of the navy for the week ended Feb. 23, 1901:

Asst.-Surgeon R. C. Holcombe, detached from the *Glacier*, and to duty with detachment of marines at Pollok, P. I.

Surgeon J. W. Ross, U. S. N., retired by special order Department of Cuba, Feb. 15, 1901, to report to the chief sanitary officer, City of Havana, for duty.

Health Reports.

The following cases of smallpox, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 23, 1901:

SMALLPOX—UNITED STATES.

California: Los Angeles, Feb. 2-9, 1 case; San Francisco, Feb. 2-9, 7 cases.

Florida: Jacksonville, Feb. 9-16, 5 cases.

Illinois: Chicago, Feb. 9-16, 14 cases.

Kansas: Wichita, Feb. 9-16, 9 cases.

Louisiana: New Orleans, Feb 9-16, 4 cases, 4 deaths.

Michigan: Manistee, Feb. 9-16, 3 cases.

Minnesota: St. Paul, Jan. 26-Feb. 9, 8 cases.

New Hampshire: Manchester, Feb. 9-16, 1 case.

New York: New York City, Feb. 9-16, 25 cases, 6 deaths.

Ohio: Ashtabula, Feb. 9-16, 3 cases; Cleveland, Feb. 9-16, 48 cases; Youngstown, Feb. 9-16, 1 case.

Pennsylvania: Allegheny City, Feb. 9-16, 3 cases; Erie, Feb. 9-16, 1 case.

South Carolina: Greenville, Feb. 9-16, 1 case.

Tennessee: Memphis, Feb. 9-16, 19 cases, 1 death; Nashville, Feb. 9-16, 9 cases.

Wisconsin: Green Bay, Feb. 10-17, 1 case; Milwaukee, Feb. 8-16, 1 case.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Jan. 19-26, 1 death.

Great Britain: Bradford, Jan. 6-13, 15 cases, 2 deaths.

Italy: Naples, Jan. 20-30, 26 cases, 2 deaths.

Mexico: City of Mexico, Jan. 27-Feb. 3, 1 death.

Russia: St. Petersburg, Jan. 19-26, 8 cases, 1 death; Odessa, Jan. 19-26, 13 cases, 8 deaths.

Scotland: Glasgow, Jan. 25-Feb. 8, 34 deaths.

Straits Settlements: Singapore, Dec. 22-29, 1 death.

YELLOW FEVER.

Cuba: Havana, Feb. 2-9, 3 cases, 1 death.

PLAGUE.

China: Hongkong, Jan. 5-12, 2 deaths.

Japan: Formosa, Tainan, Jan. 1-16, 28 cases, 22 deaths.

CHOLERA.

Straits Settlements: Singapore, Dec. 22-29, 16 deaths.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

American Medical Association

VOL. XXXVI. CHICAGO, ILLINOIS, MARCH 16, 1901. No. 11.

Address.

THE STUDY OF ANATOMY.*

LEWELLYS F. BARKER, M.B. (TOR.)
CHICAGO.

With the advent of October, with its cool and bracing days and restful nights, there is regularly a quickening of activities in academic circles. The occupant of a professorial chair, re-invigorated by temporary sojourn in forest or field, at the seaside or in the hills, resumes his teaching with renewed enthusiasm, and engages again in that original investigation which represents the most absorbing interest of his life. The student, too, perhaps as yet less conscious of the actual need of an occasional remission from his labors, has nevertheless had his holiday, and returns to the college of his choice ready for another season of diligent application, and eager to begin once more the arduous tasks which the pursuit of knowledge entails.

It has long been customary in colleges in which medicine is taught, to call a meeting of the faculty and students at the beginning of the autumn session. Such a meeting permits of the reunion of former teachers and students, and the introduction and welcoming of new teachers and new students. It gives, further, opportunity for the making of certain special remarks; and I have noticed that there is almost universally a tendency on the part of the faculty to grant the privilege of remark-making to some member of it who has lately been added to the staff. Being myself one of the most recent additions to an already large staff-family, the privilege has this year been gracefully allotted to me. However great a sacrifice on the part of my colleagues this may represent, the new-comer, on this occasion, like the distinguished member of the faculty who last year addressed you, considers it a great favor to have the opportunity of expressing the pleasure he has in coming among you and being counted one of you, and to meet with an occasion on which he can, more or less generally, indicate the aims and scope of the science which he represents, and so publicly justify the position which he holds. Fortunately, in this latter respect, the task is an easy one, for anatomy has in medicine long ago won its place as a science essential as a basis for all subsequent medical studies, and, moreover, my predecessors in office have been men of such sterling merit, power and inspiration, that the subject is here appreciated and reverenced. Especially true is this of him who has immediately preceded me as the occupant of the chair, and who has left it in order to accept a chair of surgery; while we commiserate anatomy on losing so able a representative, we must congratulate surgery on the enlistment in its service of so well-trained and enthusiastic an anatomist. He has, at this College, developed, among other things, a course in surgical anatomy—easily one of the best in America—and this part of the anatomic work he has promised, for the present at least, to retain. You join with me I know, in wishing my colleague, Professor Bevan, a continuation of that success which he has already attained in the field of his ultimate choice.

The year in which we live marks an important epoch in the history of the College. Of a whole series of advances, I wish to call attention especially to one. Beginning with this autumn quarter, a closer relationship than has ever existed before between Rush Medical College and the University of Chicago has been established. Not entirely satisfied, for what true lover long is, with that "sisterly" relationship which the term "affiliation" represents the College has this year appointed to two of its fundamental chairs—physiology and anatomy—men who are already occupants of chairs in the same sciences at the University of Chicago. That such closer bond of union can not fail to be of the greatest value, both for Rush Medical College and for the University of Chicago, I confidently believe. That it is only the forerunner of a still deeper intimacy, many I am sure, both in the University and the College, fondly hope.

On thinking over anatomical subjects in the search for material for this address, the ideas which came to me grouped themselves, in the main, under two headings: 1. What does the science of anatomy include? 2. How can the study of anatomy best be prosecuted? Each of these headings corresponds to matter enough for any single occasion; I have therefore decided to spend the time in a consideration of the former of the two questions, and to reserve for another time and place what I have gathered in answer to the latter.

Of the whole group of the natural sciences, there is perhaps no other member, the province of which is less well understood by the general public than is the science of anatomy. As ordinarily thought of by the layman, it is a science, the study of which necessarily precedes the practical work of medicine and surgery; a science which is largely if not wholly descriptive, and one which, to be mastered, requires prolonged occupation, scalpel in hand and pipe in mouth, with dead and partially decomposed human beings. Such a view of the science, though perhaps not surprising when we recall the methods by which anatomy—so-called—has frequently in this and other countries, been prosecuted, could, I do not need to tell you, be scarcely more widely removed from the truth. Anatomy is not simply a descriptive science; the study of it as a preparation for practical medicine and surgery represents only one side of its interest and usefulness; the scalpel is now perhaps the coarsest instrument it employs; its work is by no means confined to the human body alone, much less to the dead human body, and when it does deal with the

---

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Feb. 14 to 20, 1901, inclusive:

George W. Adair, major and surgeon, U. S. A., from Fort Sheridan, Ill., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Bailey K. Ashford, lieutenant and asst.-surgeon, U. S. A., to accompany recruits from Fort Slocum, N. Y., to the Presidio of San Francisco, Cal., and return to his proper station.

Dallas Bache, colonel and asst.-surgeon-general, U. S. A., leave of absence on account of sickness.

Guy G. Bailey, acting asst.-surgeon, leave of absence extended.

Charles M. Gandy, captain and asst.-surgeon, U. S. A., from Fort Slocum, N. Y., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

John J. Gilhuley, acting asst.-surgeon, from Bridgeport, Conn., to temporary duty in the Department of the East.

Charles R. Greenleaf, colonel and asst. surgeon-general, U. S. A., from duty in the Division of the Philippines, to take effect June 1, 1901, then to proceed to San Francisco, Cal., for duty as chief surgeon.

Frederick C. Jackson, acting asst.-surgeon, now in San Francisco, Cal., to temporary duty in the Department of California.

William P. Kendall, major and surgeon, Vols., from further duty in the Division of the Philippines to duty at Fort Slocum, N. Y.

John S. Marshall, dental surgeon, U. S. A., from Washington, D. C., to Philadelphia, Pa., on official business.

Edward B. Moseley, major and surgeon, U. S. A., from the Division of the Philippines to duty at Fort Sheridan, Ill.

Robert T. Oliver, dental surgeon, from Washington, D. C., to Philadelphia, Pa., on official business.

George H. Penrose, major and surgeon, Vols., to temporary duty in the Department of California.

Walter Reed, major and surgeon, U. S. A., member of a board convened at the Army Medical Museum, Washington, D. C., to examine candidates for appointment in the Medical Department of the army.

Navy Changes.

Changes in the Medical Corps of the navy for the week ended Feb. 23, 1901:

Asst.-Surgeon R. C. Holcombe, detached from the *Glacier*, and to duty with detachment of marines at Pollok, P. I.

Surgeon J. W. Ross, U. S. N., retired by special order Department of Cuba, Feb. 15, 1901, to report to the chief sanitary officer, City of Havana, for duty.

Health Reports.

The following cases of smallpox, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 23, 1901:

SMALLPOX—UNITED STATES.

California: Los Angeles, Feb. 2-9, 1 case: San Francisco, Feb. 2-9, 7 cases.

Florida: Jacksonville, Feb. 9-16, 5 cases.

Illinois: Chicago, Feb. 9-16, 14 cases.

Kansas: Wichita, Feb. 9-16, 9 cases.

Louisiana: New Orleans, Feb 9-16, 4 cases, 4 deaths.

Michigan: Manistee, Feb. 9-16, 3 cases.

Minnesota: St. Paul, Jan. 26-Feb. 9, 8 cases.

New Hampshire: Manchester, Feb. 9-16, 1 case.

New York: New York City, Feb. 9-16, 25 cases, 6 deaths.

Ohio: Ashtabula, Feb. 9-16, 3 cases; Cleveland, Feb. 9-16, 48 cases; Youngstown, Feb. 9-16, 1 case.

Pennsylvania: Allegheny City, Feb. 9-16, 3 cases; Erie, Feb. 9-16, 1 case.

South Carolina: Greenville, Feb. 9-16, 1 case.

Tennessee: Memphis, Feb. 9-16, 19 cases, 1 death: Nashville, Feb. 9-16, 9 cases.

Wisconsin: Green Bay, Feb. 10-17, 1 case: Milwaukee, Feb. 8-16, 1 case.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Jan. 19-26, 1 death.

Great Britain: Bradford, Jan. 6-13, 15 cases, 2 deaths.

Italy: Naples, Jan. 20-30, 26 cases, 2 deaths.

Mexico: City of Mexico, Jan. 27-Feb. 3, 1 death.

Russia: St. Petersburg, Jan. 19-26, 8 cases, 1 death; Odessa, Jan. 19-26, 13 cases, 8 deaths.

Scotland: Glasgow, Jan. 25-Feb. 8, 34 deaths.

Straits Settlements: Singapore, Dec. 22-29, 1 death.

YELLOW FEVER.

Cuba: Havana, Feb. 2-9, 3 cases, 1 death.

PLAGUE.

China: Hongkong, Jan. 5-12, 2 deaths.

Japan: Formosa, Tainan, Jan. 1-16, 28 cases, 22 deaths.

CHOLERA.

Straits Settlements: Singapore, Dec. 22-29, 16 deaths.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The *qualifications for membership require that the applicant be* a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as *above, with a receipt for their subscription to* The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the *succeeding January, at which time the treasurer sends* a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive *property of the* Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no *objection will be made to the reproduction of* anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the
American Medical Association

Vol. XXXVI. CHICAGO, ILLINOIS, MARCH 16, 1901. No. 11.

Address.

THE STUDY OF ANATOMY.*

LEWELLYS F. BARKER, M.B. (Tor.)
CHICAGO.

With the advent of October, with its cool and bracing days and restful nights, there is regularly a quickening of activities in academic circles. The occupant of a professorial chair, re-invigorated by temporary sojourn in forest or field, at the seaside or in the hills, resumes his teaching with renewed enthusiasm, and engages again in that original investigation which represents the most absorbing interest of his life. The student, too, perhaps as yet less conscious of the actual need of an occasional remission from his labors, has nevertheless had his holiday, and returns to the college of his choice ready for another season of diligent application, and eager to begin once more the arduous tasks which the pursuit of knowledge entails.

It has long been customary in colleges in which medicine is taught, to call a meeting of the faculty and students at the beginning of the autumn session. Such a meeting permits of the reunion of former teachers and students, and the introduction and welcoming of new teachers and new students. It gives, further, opportunity for the making of certain special remarks; and I have noticed that there is almost universally a tendency on the part of the faculty to grant the privilege of remark-making to some member of it who has lately been added to the staff. Being myself one of the most recent additions to an already large staff-family, the privilege has this year been gracefully allotted to me. However great a sacrifice on the part of my colleagues this may represent, the new-comer, on this occasion, like the distinguished member of the faculty who last year addressed you, considers it a great favor to have the opportunity of expressing the pleasure he has in coming among you and being counted one of you, and to meet with an occasion on which he can, more or less generally, indicate the aims and scope of the science which he represents, and so publicly justify the position which he holds. Fortunately, in this latter respect, the task is an easy one, for anatomy has in medicine long ago won its place as a science essential as a basis for all subsequent medical studies, and, moreover, my predecessors in office have been men of such sterling merit, power and inspiration, that the subject is here appreciated and reverenced. Especially true is this of him who has immediately preceded me as the occupant of the chair, and who has left it in order to accept a chair of surgery; while we commiserate anatomy on losing so able a representative, we must congratulate surgery on the enlistment in its service of so well-trained and enthusiastic an anatomist. He has, at this College, developed, among other things, a course in surgical anatomy—easily one of the best in America—and this part of the anatomic work he has promised, for the present at least, to retain. You join with me I know, in wishing my colleague, Professor Bevan, a continuation of that success which he has already attained in the field of his ultimate choice.

The year in which we live marks an important epoch in the history of the College. Of a whole series of advances, I wish to call attention especially to one. Beginning with this autumn quarter, a closer relationship than has ever existed before between Rush Medical College and the University of Chicago has been established. Not entirely satisfied, for what true lover long is, with that "sisterly" relationship which the term "affiliation" represents the College has this year appointed to two of its fundamental [illegible] and anatomy—men who are already [illegible] in the same sciences at the University of Chicago. That such closer bond of union can not fail to be of the greatest value, both for Rush Medical College and for the University of Chicago, I confidently believe. That it is only the forerunner of a still deeper intimacy, many I am sure, both in the University and the College, fondly hope.

On thinking over anatomical subjects in the search for material for this address, the ideas which came to me grouped themselves, in the main, under two headings: 1. What does the science of anatomy include? 2. How can the study of anatomy best be prosecuted? Each of these headings corresponds to matter enough for any single occasion; I have therefore decided to spend the time in a consideration of the former of the two questions, and to reserve for another time and place what I have gathered in answer to the latter.

Of the whole group of the natural sciences, there is perhaps no other member, the province of which is less well understood by the general public than is the science of anatomy. As ordinarily thought of by the layman, it is a science, the study of which necessarily precedes the practical work of medicine and surgery; a science which is largely if not wholly descriptive, and one which, to be mastered, requires prolonged occupation, scalpel in hand and pipe in mouth, with dead and partially decomposed human beings. Such a view of the science, though perhaps not surprising when we recall the methods by which anatomy—so-called—has frequently in this and other countries, been prosecuted, could, I do not need to tell you, be scarcely more widely removed from the truth. Anatomy is not simply a descriptive science; the study of it as a preparation for practical medicine and surgery represents only one side of its interest and usefulness; the scalpel is now perhaps the coarsest instrument it employs; its work is by no means confined to the human body alone, much less to the dead human body, and when it does deal with the latter, the material can be so well preserved that even the fragrant Havana is said to be more offensive to some sensitive souls than are the odors from the well-kept preparation room.

---

* Delivered before the Faculty and Students of Rush Medical College, Oct. 5, 1900.

Even medical men differ markedly in their conception of what anatomy includes, their ideas being largely based on the kind of anatomy they themselves were taught, and on the anatomic needs of the particular branch of medicine which, after graduation, they have cultivated.

Nor is there uniformity of opinion among the pure anatomists themselves, as can be readily seen by a perusal of the various addresses made by scientific anatomists in different parts of the world during the last twenty years. A free expression of opinion on the subject has, however, gone far to make the aims and scope of the science clearer, until at present its principal representatives are more clearly in accord, with regard to them, than ever before. In what this accordance consists, I can, I believe, make clearest to you by glancing briefly at the various steps through which the science has passed from the period when the earliest anatomic observations were recorded to the present day.

There can be no doubt that from the earliest times, curiosity concerning, and interest in the make-up of the human body has existed. The references to man's body and its organization frequently to be met with in the pages of the old Hindu Vedas and of the earliest writings of all the oriental nations, make this very evident. Nevertheless, the awe in which men stood before the human cadaver, together with the penalties threatened by religious leaders for any molestation of it, appear to have effectually prevented any systematic examinations; and the little knowledge possessed by the ancients, aside from the conclusions drawn from animals killed for food or for sacrifice, seems to have been drawn from the instances in which, through the violence of war, the chase, or the natural elements, the human body became dismembered or eviscerated.

The earliest dissections of the human body of which no doubt exists, are those which were undertaken at the Alexandrian School, by Herophilus and Erasistratus, supported and protected by the intelligent Ptolemaic rulers. The name of Herophilus is still familiar to every beginner of anatomic studies in the term Torcular Herophili. The statement is made, though I hope it is not true, that these daring anatomists went so far, with Ptolemy's sanction, as to dissect living criminals, from which Tertullian designated Herophilus as *lanius*.

This opportunity for the anatomic investigation of the human body appears to have been unique, and it continued only for a short time. Even Galen's studies, the results of which were held, for the following ten centuries at least, to be infallible, were limited to the bodies of animals; he recommended, it may be remembered, the study of the bodies of apes and swine—the animals which in his opinion were nearest to human beings. After Galen, the natural horror which the examination of the dead body excites, together with the edicts of the church against dissection, prevented any further progress of descriptive human anatomy for a very long period. The church declared that Galen had been infallible, and that therefore no further anatomic studies were necessary. Fortunately for science, which knows but little of infallibility, certain of its votaries in high favor at Rome, gained permission in the fourteenth century to make dissections of human bodies, and to use them for demonstration before students. Mondini in Bologna again opened the path for scientific anatomic inquiry, and started in Italy a movement which placed that country, as far as medicine is concerned, in the lead. Students from distant lands were attracted, as they always have been and always will be, to the point where progress was making the greatest headway.

The great Vesalius, often known as the father of anatomy, was among these wandering scientists. Born in Belgium, and educated in France, he prosecuted his anatomic studies in Italy, especially when professor at Padua, to such a degree that he merits a place among the world's greatest reformers. This energetic, truth-seeking, idol-breaking, authority-denying man dared to look at things as he saw them, rather than as Galen had said they should be, and thus made discoveries of the first importance in anatomy; by his artistic powers he rendered many of them imperishable; best of all, he broke forever the tyranny of tradition in anatomic knowledge, and threw wide open the gate by which men must always enter in the pursuit of anatomic truth. Vesalius was a contemporary of Luther; the year of his death is that of the birth of Galileo and of Shakespeare.

It was the spirit which animated Vesalius which later led William Harvey, the founder of physiology, to the discovery of the circulation of the blood, and Giovanni Battista Morgagni, the founder of pathology, to that mode of conception which Virchow has designated "the anatomical idea in medicine." It is the spirit which is embodied in every scientific worker of today who accepts the records of past investigation only as a guide—a guide which must be fallible since it is human—and which, therefore, must be repeatedly controlled; a guide which needs constant revision on account of the ever-increasing extension of the domain of sense, and one which, if not added to significantly by the scientist in his lifetime, will stand as an everlasting witness to his inefficiency, a perpetual testimony to his lack of consequence.

Like all the natural sciences, anatomy in its earlier stages consists of necessity, in the amassing in an empirical way of a store of naked facts. In other words, the subject is purely descriptive until a sufficient number of facts have been collected to make their arrangement and classification worth while. Adequate descriptions are based on intelligent observation which in turn is dependent on the skilful use of the organs of sense, including the means which modern technique is ever inventing to extend them. The body is examined externally and internally in its various parts; it is looked at, it is felt. The size, shape, color, weight, consistence, and reciprocal relations of the parts are noted; the results are recorded, the attempt being made to establish the material content of the science with all possible certainty, sharpness, and clearness. The parts have first to be distinguished and named, then accurately described, their physical characters being established in language. The description of a natural object that shall call up in the mind of the reader a precise image of the object, and that shall serve as a reliable guide to a succeeding observer, does not fall within the province of every man's capacity; happy indeed is the anatomist who possesses the power, for, as has more than once been pointed out, an exact and clear description of the known is often of as great value as the so-called "discovery" in the region of the unknown.

The satisfactory naming of the various parts alone is a task of far greater difficulty than at first appears.

An object must be studied for a long time, in many countries, and by men who know the relations of anatomy to every subject with which that science is allied, before a name for a part which shall be in accord with all the requirements can be decided on. Almost every part has at various times received a series of names; periodic revisions of nomenclature by representative committees are accordingly desirable in order to arrive at uniformity among anatomists and to relieve the science of an immense number of names, since at best it must be grieviously burdened.

Ever since the time of Vesalius there has been an unbroken series of anatomic observers who have devoted their powers to the attaining of skill in dissection and anatomic description; with energy and endurance and often at great personal sacrifice, this band of anatomists has developed this side of our science until it has reached the degree of precision which characterizes it to-day; a state, indeed, which many believe to be practically complete and incapable of further progress. Of the difficulties overcome by Americans in helping with this work since Mr. Giles Firman made the "first anatomy in the country," a good idea can be gained from the admirable historical review that we owe to E. M. Hartwell. While it is obvious that there must be a temporal limit to the discoveries which the naked eye is to make in anatomic fields, one has nevertheless only to refer to the current journals to see that the limit has not yet been reached. But the limits of progress in anatomic description will by no means be synchronous with those of macroscopic discovery of the objects themselves; indeed, considering the complexity of man's architecture and the different and ever-varying view-points whence descriptions are being written, it is scarcely conceivable that man will ever attain to descriptions which will be satisfactorily final. To the surgeon, to the artist, to the physiologist, to the scientific anatomist the details of parts are of utterly different significance; the varying scale of anatomic values requires in each case a special description; an objective characterization of all details, merely as such, would make anatomic descriptions so ponderous and chaotic as to render them totally useless to anybody. Nor can illustrations, in colors and otherwise, which are perhaps even more valuable than anatomic descriptions, ever be completely objective. The exact plates of anatomic objects which approach of late years ever nearer to that degree of accuracy which will permit of the taking from them of mathematical measurements, never attain actually to perfection; there must always be an element of subjectivity in them which may be inconsonant with the needs of some other observer at some other time.

Again, the greater or less degree of variability to which all parts of the animal body are subject makes it difficult for anatomists to agree as to what shall be called normal, and thus the same object has frequently to be described in several different ways, and pictorially multiply exactly represented. There thus remains, and ever will remain, a task for the anatomist in the domain of anatomic description and illustration (Cf. His, W.).

If it be true that in the fields just referred to there is still much work to be done, the statement is all the more justified with regard to the taking of measurements and weights of the body and its parts. The shape of the natural objects is nearly always such that the localization of fixed points whence measurements can be taken is rendered very difficult—so difficult that frequently the comparison of the measurements of one observer of an object with those of another observer of the same are useless. Again, owing to the variability of the bodily dimensions in the two sexes, in different races, at the various ages of life, according to individuality or under different physiologic conditions, unless a whole series of data accompanies a given measurement, the result may be of no value to a succeeding observer. In modern anthropology, however, definite criteria are always attended to, and the measuring method is proving to be of the highest service in the elucidation of the questions which that science has to solve.

The difficulties of anatomic measurement in large part obtain also when the weighing of anatomic objects is undertaken. Notable results have already been obtained, however, not the least of those in connection with the central nervous system being gained through the comparatively recent work of my colleague, H. H. Donaldson, in the University of Chicago. The application of the method to the determination of the normal by H. Thoma may also be referred to as the beginning of a long series of investigations which, in the end, can scarcely fail to be of the greatest importance. As His, who has discussed this and the foregoing subjects in an admirable manner, points out, it is difficult to imagine how the study of variations in constitution is to be approached unless this and similar methods are the ones employed. As he says, it must be of decisive influence for the physiologic capability of an individual, whether in his organism the musculature predominates over his nervous system, his epithelial tissues or his glandular organs, whether his heart is relatively large or small, whether accordingly it can increase the average blood-pressure in the arteries to a great or to a slight degree, whether the man has a large or small liver, or whether he has a long or short alimentary canal. The study of anatomy with the unaided sense organs is, as we have seen, one of no small magnitude, and one not yet complete. What then is to be said of that descriptive anatomy which invades the territory into which the eye, only with the aid of the microscope, can penetrate. The field of the microscopic anatomist is at least a thousand times wider than that of the macroscopic worker, and in that field what has been said above concerning description, pictorial representation and anatomic measurement equally holds good. It will yet be long ere the collection of microscopic data will have been completed. New methods open up new problems, and at present progress, descriptive microscopic anatomy may probably occupy workers for centuries to come. Even with the methods and microscopes now at our disposal we have entered a museum the largest part of which has yet to be catalogued, and who can say what new doors the methods and the microscopes of the century just before us are about to open up. The science of histography is almost as undeveloped as was geography before the voyage of Columbus. Between the histographic world of to-day and the architectural world of stereochemistry who will dare to prophesy what rich territories may exist?

The mere observation and registration of naked facts does not, however, satisfy for long the cravings of the investigating human intelligence. Indeed, there is something of a blunting character about the process if long continued without the synchronous operation of other faculties of the intellect. Man is a classifying and generalizing animal; there lies deep in his nature a desire to arrange the facts he observes in an orderly manner, with the object of understanding them. It is in the attempt to satisfy this human tendency that anatomy, instead of remaining a purely descriptive science, becomes elevated to a plane on a level with the other inductive sciences.

Evidences of attempts at anatomic classification are found among the earliest anatomists. The close resemblance of certain parts to one another soon gave rise to the idea of organic systems—such as the muscular and nervous systems. The keen observations of Aristotle on the partes similares and the partes dissimilares may be recalled, as well as those of Fallopius, outlined in his "Tractatus quinque de partibus similaribus." It was left to the organizing brain of the young Frenchman, F. Xavier Bichat, to get a grasp, for the first time, of the relation of elementary tissues to the general architecture of the body. Although, through over-work and impecuniosity, his penetrating eyes were forever closed at the early age of about 31 years, Bichat left behind him three treatises—his "Traité des membranes," his "Récherches physiologiques sur la vie et la mort," and his "Anatomie générale"—a legacy so valuable that we can not help lamenting, with wondering regret, the too early arrest of his labors. He recognized the fact that whereas in chemistry the more complex bodies are composed of simple elements, so in the architecture of man's body simple tissues are variously combined to form the complex mixture of tissues which are ordinarily known as organs. He distinguished some twenty-one systems or tissues—the cellular, the osseous, the fibrous, the cartilaginous, the nervous, the muscular, the medullary, etc.—basing his classification on the manner in which each tissue behaves in the presence of various reagents, the physical and vital properties of each, and, finally, the character of each when met with under diseased conditions. In other words, Bichat was the founder of the modern science of histology, or, as it is sometimes designated, general anatomy.[1]

Before following the progress of anatomy further along this line, a word must be said concerning what must be regarded perhaps as the first direction taken by the investigating mind toward the understanding of organic forms, namely, the physiologic—in its first stages, the purely teleological.

As has long since been pointed out, the language of anatomy is sufficient evidence of the long existence of the teleological conception of this science. For thousands of years the individual parts of the body have been known as "organs," and the processes going on in them as "functions." Just as function was unthinkable without a corresponding organ, so an organ without function was inconceivable, and thus, wherever in the series of well-understood parts of the body one remains over whose purposeful participation in the processes of life is not understood, toward this is directed over and over again the mental acumen of the investigator to assign to the reluctant organ a definite significance.[2] It is not my purpose here to enter into a discussion of teleology. The world has been widely enough explored to utterly dispose of that gross anthropomorphic form of teleology which pointed to a humanly scheming architect of the universe, and whether or not we accept some more correct form of teleology is, at present, a matter for individual opinion. This much is certain, that while no teleological view of Nature actually explains the organization of a human body, the teleological conception has been particularly heuristic in its effects in the investigation of the relation between the physical processes in, and the physical characters of, the various parts of the body. Ever since Galen, though animated by a false teleology, wrote his "De usu partium," in which the size, position, number, consistence and structure of the various parts are treated as facts which can be understood only through the investigation of the purposes which they subserve, this mode of consideration has been among the most influential. Even to-day a large part of the profitable research undertaken by anatomists, physiologists and pathologists has for its aim the elucidation of the relation of structure to function, especially in microscopic domains. The work done in Ludwig's laboratory was largely of this nature, and as recently as 1883 H. v. Meyer[3] has asserted that the only possible way of understanding the organs is to proceed to the study of them from the physiologic viewpoint. But if this were true, then all scientific anatomy would be physiology, a statement which narrow-minded physiologists might applaud, but which broader men know to be untrue. Physiology is one of the daughters of anatomy, and is not likely so soon to forget the fifth commandment. Johannes Müller was the last great scientist who covered both fields of anatomy and physiology; since his time investigators have cultivated one of the two at the expense of the other, a division of labor which we must recognize on the whole as beneficial, though that it is accompanied by certain drawbacks must also be confessed. Especially difficult is it to sharply separate the study of structure from that of function in the science of cytology, founded by Schleiden and Schwann, pupils of Johannes Müller in the fourth decade of this century. The development of the cell-doctrine, modified as it was somewhat later by the introduction of the protoplasm theory by Max Schultze, marks a most important epoch in the history of both anatomy and physiology. Its value for the more practical side of medicine is sufficiently in evidence when one of its direct outgrowths, the cellular pathology of Rudolph Virchow, is recalled. The appalling elaboration of technical methods during the last few years has led to the accumulation of cytographic data which remove all the comfort we once had in looking on the cells as elementary structures. Though cytophysiology is as yet far behind cytography in its state of development, there no longer remains any doubt that in approaching the cell we stand before an organism of enormous complexity of constitution, endowed with functional activities which must for long remain to us unfathomable. Any one who has worked much with protoplasm and nucleus, with archiplasm and centrosome, with cell-fibrils and cell-granules under various physiological conditions, can not fail to appreciate the fact that here only the threshold of inquiry has been crossed—the exploration of the real nature of the cell only just begun. Indeed, the evidence is fast accumulating in favor of the opinion that many of these morphological cell-constituents represent precipitates due to the action of reagents, and the laws governing their regular appearance under definite conditions are being investigated. It is exactly in these studies that structural and functional investigation still do well to go hand in hand, a fact which a survey of the cytological hand-books, now becoming so numerous, will show, is meeting with general recognition. I believe it was Du Bois Reymond who ventured the statement that "an ocean steamer, with all its machinery and intricacies of construction, is far less complicated in its composition than a cell." Would that the cell were no more complicated than the ocean steamer in construction!—the modern investigator would then soon be ready with the solution of its problems. Alas, the difficulties are not confined to the study of these organisms as individuals; already we have entered on the investigation of their social relations, and cell-altruism and cell-egoism, cell-states and revolutionary cells are discussed as actively among cytologists as are the similar social questions concerning organic individuals of another order by the people at large. Further, in cytophysics and cytochemistry, research is at present most active—these subjects representing one of the most interesting subdivisions of recent physiology. Should the gulf between the present microscope picture of the cell and its chemical structure ever be bridged, stereochemistry would enter into the domain of anatomy. So much in general with regard to the physiologic view-point in anatomy!

Closely allied to the foregoing, and in reality an offshoot from it, is the mode of consideration of the surgical and topographical anatomist. In this branch the individual regions and cavities of the body are dealt with with regard to the reciprocal position of the various organs and systems. Surgical anatomy studies these relations only in as far as they are of importance in operative procedures; topographical anatomy, a wider subject, studies the relations mentioned independently of their significance to the surgeon. The various regions of the body are studied sometimes in layers, sometimes with regard to serial clues to a particular structure. Sections of frozen cadavers have here proved to be of great value for the study of relations and for helping the student to make mental reconstructions of the parts analyzed by dissection. Surgical and topographical anatomy are thus seen to be subjects of very high practical importance—the former especially for the surgeon, the latter also for the worker in internal medicine. It is this kind of anatomy which has been brought to so high a state of cultivation in Great Britain, and especially in London, where most of the anatomy has been taught by men in surgical practice. Valuable as such instruction is for surgery and medicine, it should not be forgotten that it is applied anatomy rather than anatomy proper, and no less a scientist than Macalister has deplored the lack of advances in anatomy in England, attributing it largely to the one-sided mode of instruction in vogue, and to the examinations, to the passing of which the teaching is, in large part, directed. Surely certain morphological considerations are as important for the student of anatomy as the learning by heart of the various relations of an artery, especially if the student is not to become a surgeon; it would be melancholy indeed if there were not at least some members of the anatomic classes who regarded the study of the architecture of the brain and spinal cord as interesting and as important as that of the perineum.

But anatomy as a science would never have attained to the dignified position it now holds had the minds engaged with it remained satisfied, after observing and registering its material content, with attempting the explanation of the human body from the physiologic view-point or with exhausting the possibilities of its relation to the surgeon's knife.

As in the other natural sciences, the causality-need of the intelligence has forced the anatomist to undertake the investigation of the origin of the organic forms which he studies, and of the relations of these forms to other similar and dissimilar organic forms accessible to examination. In other words, the comparative and the genetic methods of study have been resorted to. Comparative anatomy and embryology together constitute morphology, at least in the sense in which the term is ordinarily used, and in morphology we recognize the part of anatomy which makes it truly worthy of being designated a science.

In the application of the comparative method, not only are the different parts of the human body compared with one another—the arms with the legs, the brain with the spinal cord, the skull with the vertebral column, the various segments and segmental partitions with one another, but man, recognized as a member of a long series of animals, is compared with each of them in turn, and they with one another, with the object of establishing groups of type forms and of learning the plan of architecture, not only of the single creature, but also of the whole series. At first, anatomists studied the forms which to them seemed to resemble man most closely, but the gradual transition from one form to another was so striking that animal after animal was studied until, finally, the whole world of organisms has been submitted to the examination of the comparative investigator. Oken and Goethe, Cuvier, Meckel, Geoffroy St. Hilaire, Lamarck, Wallace, Darwin, Haeckel, Huxley, Gegenbaur and Leidy are names which have become very familiar to us in this field. The world of living creatures is a unitary system, of which man is an inseparable portion. First, when the whole system has been worked through do the form and significance of many of man's parts become intelligible. The animal series can be thought of as a tree with the simplest forms at the root, the trunk branching at its origin, each branch in turn subdividing into limbs and twigs until the highest degree of differentiation is reached. It is this recognition of the lawful relation of organisms to one another which the study of comparative anatomy has afforded us. Such a recognition, now general, was little less than startling to those who first arrived at it. That it pointed to some more general law, was obvious. As Goethe, himself no mean participator in comparative studies, beautifully expressed it:

> Alle Gestalten sind ähnlich und keine gleichet der anderen,
> Und so deutet das Chor auf ein geheimes Gesetz.

Has this secret law been discovered? Many believe so, and look upon Darwin's doctrine of descent as a generalization worthy, on account of its scientific value, of being placed side by side with Newton's theory of gravitation. Whether the evolutionary doctrine be unequivocally accepted or not, certain it is that the relationship of forms which comparative anatomy reveals finds in this genealogic conception of Darwin a more satisfactory explanation than any other hitherto offered.

Closely allied to the phylogenetic mode of consideration is that which we designate as the embryologic, ontogenetic or developmental. In the human species, as in every other, the life of the individual member is of short duration; each human organism has a beginning, a period of growth and development, followed, even in the life of maximum length, in the course of a few decades by decline and death. Generation follows generation as wave follows wave on the surface of a ruffled sea. In the transference of life from one generation to another the material substratum sinks to a minimal amount—the new human being begins as a fertilized egg-cell 1/120 of an inch in diameter, weighing only a minute fraction of a gram. From this simplest of beginnings it gradually passes through a long series of developmental stages, the character of these stages varying somewhat under environmental influences, each stage being the necessary consequent of a preceding one, and at the same time the necessary antecedent of the stage which follows it, until, finally, the organism attains to the fulness of differentiation of which, under the circumstances of its environment, it is capable.

In this long series of developmental stages, which every mammal passes through, the earliest are very, very simple and correspond in form closely with the lower forms in the animal kingdom. But as cell-division in the embryo proceeds, the shaping of the organism becomes more complex, resembling higher and higher forms of animal life, until, finally, that of mammals is assumed. Even at this period the unskilled observer might easily be confused if he were required at a glance to distinguish a human embryo from those of several other mammals at a similar period of development. Ultimately, the differential characters of the species become clearly marked, and even the tyro can easily recognize them. The more skilled the observer, however, the earlier in the development will the species-criteria be decisive.

Comparative embryology becomes all the more astonishing a study when we realize that the embryologic history of every higher animal is, for a long period at least, almost identical with that of a whole series of allied forms. No wonder then, this state of things being acknowledged, that the embryologists, like the comparative anatomists, have pictured the genetic relations of the different animal forms also as a tree, a tree which on close examination is found to accord very closely with the tree of relationship constructed by the comparative anatomists.

Comparative anatomy and embryology are therefore closely interwoven subjects, and each may, in a way, be looked upon as a control for the other, though each has its special problems, and each sets about the solution of these in a manner peculiar to itself. Take, for example, the attempts at an explanation of the series of forms through which the individual passes in its development. Many comparative anatomists, accepting Darwin's doctrine of the origin of the species through a struggle for existence among generations influenced by heredity and variation, would explain the development of the individual member of a species as a temporarily compressed recapitulation of the developmental course of the species as a whole. While this doctrine that "ontogeny repeats phylogeny" has been maintained by eminent scientists, there are others who are unwilling to accept what can not be proved; and some of the embryologists especially feel it their province to attempt to explain from embryologic studies alone, and without reference to phylogenetic history, the origin of the various form-stages through which the individual passes. Already great strides have been made in the direction mentioned, especially through the investigation of the laws of growth, and the field of developmental mechanics, though so lately entered upon, has proven to be one of the most fruitful of those thus far tilled. One of the foremost investigators along these lines goes so far as to assert that the growth of every organic germ must, as a process strictly regulated according to time and space, possess a mathematical expression in which the velocity of growth of each point is determined in its dependence on the time and the position. Whether such formulæ will ever be set up, and the kingdom of organic forms thus subordinated to the domination of simple numbers, seems doubtful, but in any case the conception is an interesting one. We need not, however, look into the nebulous distance for the advantages to accrue from developmental study. Near at hand are thousands of facts of the greatest importance for anatomy as a whole, and for the practical branches of medicine and surgery to be gained only through this method of study. There is scarcely a part of the body but what is now better understood than was otherwise possible. I need only mention the remarkably complicated morphology of the brain and sense organs, the distribution of the intestines, the grouping of the various voluntary muscles, the puzzling course followed by certain of the nerves and the origin of the reproductive organs in the two sexes, to call to mind some of the features which embryology has done much to illuminate.

I dare not pass by unnoticed here two phases of investigation which naturally follow upon the others, but which have only very recently begun to be extensively cultivated, viz.: those of histogenesis and comparative histology. Histogenesis stands in the same relation to comparative histology as does embryology to comparative anatomy. Indeed, the anatomist is simply pushing the microscope into embryology and comparative anatomy, and the progress made is, in a way, comparable to the advance from gross descriptive to microscopic anatomy. By histogenesis we mean the study of the development of the individual tissues, including that of the individual cells—cytogenesis. By comparative histology and cytology we refer to the comparative microscopic study of the various tissues and cells through a series of animals. The light thrown by these methods on many of the unsolved problems of structure is unexpectedly brilliant, and the future has much to hope from them; Macallum, too, has shown how important these methods can be in helping to explain certain pathologic phenomena met with in heart muscle, and there can be little doubt but that we are on the brink of the discovery of a series of relations between histogenetic conditions and pathologic processes.

Lastly, as a crowning piece to the whole system of anatomic study, experimental morphology must be recognized. As but a child among the kindred sciences, it is of robust constitution, being the offspring of vigorous parents, and, in this country especially, in an environment most suitable for its healthy growth. The anatomist is no longer confined to the study of adult forms, or of forms in their natural mode of development; he can now, to a certain extent, artificially control form-production by resorting to the experimental method. The experiments which have been made upon heteromorphism, upon the artificial production of malformations, and upon the grafting of embryos, are full of interest, so much so as to disturb the equanimity of the soberest of scientists. During the last year or two we have been—I was about to say—shocked by the bringing of the proof by my colleague, Professor Loeb, that the eggs of several species not naturally parthogenetic can be fertilized, or at any rate brought to development, in the absence of spermatozoa, solely through the action of simple physiochemical influences. With miracles such as these already performed, we can but stand in awe of the work of the future.

Most sketchily and imperfectly, I fear, I have tried to give you an idea of what the study of anatomy includes, viz.: descriptive or systematic anatomy—gross and microscopic—physiological, surgical and topographical anatomy; histology or general anatomy, including histography and cytology, comparative anatomy; embryology; comparative histology and embryology; histogenesis, and, lastly, experimental morphology. Assuredly the subject is wide. It is, I am sorry to say, too wide to be mastered in all its details even when a whole life-time is devoted exclusively to it. The scientific anatomist, after familiarizing himself with the main facts and principles of its various subdivisions, does best, in agreement with the great law of division of labor, to direct his efforts toward the acquisition and promulgation of knowledge, in some one portion of it.

BIBLIOGRAPHY.

In the preparation of this address, I have made free use of a large number of addresses made on similar occasions by other anatomists. I have had no hesitation in borrowing liberally, as will be immediately apparent to those who are familiar with the bibliography. Especially useful to me have been the addresses and papers of His, Hertwig, v. Kölliker, Macalister, Mall, and Waldeyer. The following are some of the sources consulted:

PARESIS OF THE EXTERNAL RECTI ASSOCIATED WITH IRREGULAR TABES.[*]

G. ORAM RING, A.M., M.D.
PHILADELPHIA.

The multiform clinical manifestations which constitute the symptom grouping of so-called locomotor ataxia, are believed by most modern pathologists to be caused by an atrophy or degeneration of the sensory neurons, followed by sclerosis; although as suggested by Berger, Gowers, Oliver and others, this condition is probably preceded by a low grade inflammation.

The varying symptoms, besides those caused by disease of the spinal cord, consist of disturbances of the function of special cerebral nerves, sometimes of the cerebrum and occasionally of the cerebellum.

The medulla oblongata seems to be the connecting link between the spinal and the optic nerve affection. A broad generalization of the ocular symptomatology has recently been presented in a paper by Dr. Charles A. Oliver, as the outcome of a most painstaking series of investigations based upon the study of 100 cases.

The long-recognized pre-ataxic and ataxic divisions, it is thought, should give way to the more scientific initiative or probably inflammatory stage, and later to a degenerative one.

The ocular manifestations, summarized by Swanzy, and previously very thoroughly expounded in the exhaustive treatise of Berger, are as follows: 1, atrophy of the optic nerve; 2, paralysis and ataxia of the orbital muscles; 3, pupilary alterations; 4, paralysis of accommodation; 5, narrowing of the palpebral fissure; 6, imperfect closure of the lids, associated with twitchings in the orbicularis palpebrarum; 7, epiphora; 8, reduction of intra-ocular tension.

It is to the consideration of the second division of symptoms that I will specially call attention.

Paralysis of the ocular muscles occurs in from 20 to 25 per cent. of tabetic cases. They are usually found in the pre-ataxic or inflammatory stage, and not infrequently exist as an initial symptom. Indeed, according to Gowers, in four-fifths of the cases, the paresis constituted an initial symptom. Schmeichler concludes that paresis begins, if it develops at all, with the first symptoms of tabes; at times precedes these by many years, occasionally appears suddenly, but the progress as a rule is a gradual one. After lasting for a few weeks or a few months, it may disappear, not to trouble the patient again perhaps for several years.

The two types of involvement are: the transient paralysis or paresis of a few days or weeks, and the permanent paralysis of one or more muscles. Oscillatory twitching—mostly in a horizontal direction—was first observed by Friedreich, who applied to it the term nystagmus, and thought it an ataxia of the muscles, but since this patronymic is given by ophthalmologists to those clonic spasms of the muscle which appear, even when the patient is looking directly forward, it is clear why they do not mention it or say merely, as did Mauthner, that it is supposed to occur. As to the order of involvement of the muscles, Swanzy notes the externus as the one most affected, next the oculomotor, and next, probably, the levator palpebræ. Woinow and Berger also give the externus the first place, while Erb and Charcot assign it to the oculomotor. In Javal's experience, the levator was most frequently involved and, succeeding this, the internal rectus, the externus and superior oblique being very rarely diseased. Landolt, de Watteville and Von Graefe are in entire accord with Javal in this judgment, and oppose Berger in his statement that paralysis of the internus is comparatively infrequent.

---

[*] Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In the paretic or paralytic condition, the symptom of special annoyance is the diplopia. The cause of the paresis has been regarded as a vascular disturbance or a slight ependymitis in the nuclear region. It sometimes develops into a chronic ependymitis, with granular hyperplasia. They begin, says Pierret, as nuclear, extend toward the periphery, as descending neuritis, and here continue after the nuclear affection has disappeared.

Dejerine's examinations proved that not all ocular paralyses in tabes are of nuclear origin. The muscle involvement is seldom complete, and is limited usually to one eye. The complete and permanent paralysis of an isolated orbital muscle, occasionally noted in locomotor ataxia, is probably due, according to Swanzy, to a peripheral, rather than to a nuclear disease, but occasionally a well-marked muscular paralysis, affecting a number of muscles, occurs.

It is not possible to diagnose locomotor ataxia with certainty in a patient who shows only ocular symptoms, the diagnosis between this disease and insular sclerosis remaining doubtful until general symptoms develop.

The eye muscles paralyzed in tabes have in themselves nothing absolutely characteristic. The paralysis develops rapidly and usually disappears slowly. In cases of tabes that succeed syphilis, the lesion is not syphilitic in histologic character. In this sort of case, as well as in the type in which syphilis can be excluded, the disease is a degenerative one and rarely influenced by antisyphilitic treatment. It is to be regarded as a degenerative sequel of syphilis, rather than a true syphilitic disease. This view is in accord with the experience of Dr. Mills.

The case which has formed the basis of my brief study of paresis of the external recti, as symptomatic of irregular tabes, has been under observation since Feb. 13, 1897. The period during which organic symptoms of the spinal segments, or more properly, segments of the cerebrospinal system, have been carefully noted, has been two years, the only ocular manifestation having been recurring attacks of paresis of the left external rectus muscle.

The patient is a male, aged 30, with an unusually fine mental equipment, and at his initial visit was in perfect condition physically; married, with one (healthy) child. His mother, at an advanced age, has very severe asthma. The family history is otherwise good and, as bearing on his present condition, negative. At the period of his initial visit vision was reduced to 4/200 in each eye, refraction highly myopic and astigmatic, with huge characteristic crescents, the astigmatism being against the rule. There was no muscular abnormality, excepting an exophoria of .5 degree. With the appropriate correction, the vision equaled 20/25 in each eye.

Fifteen months later—May, 1898—the patient again reported, complaining of numbness of the lips, particularly the upper, with anesthesia of the roof of the mouth, some aching in and over the left eye, apparently more aggravated during periods of constipation, but no paresis of any external eye muscles or other distinctive eye symptoms. There was left hyperphoria of 2 degrees. Four days later the same vertical error and, in addition, an insufficiency of 10 degrees of the externi-esophoria. Three days later the esophoria had increased to 16 degrees, and double images had become almost constant, but distinctly more marked at the close of a busy day, as was also the anesthesia of the roof of the mouth.

Pupilary study, beyond the slightest sluggishness, showed no abnormality. The right knee reflex was slightly diminished, also the left. There was entire absence of any hemorrhage or splotches in the *eye ground, and the form field*—beyond a slight outer contraction—was normal.

Inclined, at this early period, to regard the case as probably specific in origin, I had a consultation with his family physician and friend, Dr. Louis Jurist, who remembered having treated him for a skin rash some years previously, which he regarded as specific. The patient stoutly denied the existence of any such condition, and no other symptoms, *primary or secondary*, were present. At my suggestion he was placed on mercurial inunctions, followed by iodids. At the end of about two months the diplopia had disappeared, but the *remaining* symptoms were about *in statu quo;* the treatment was demoralizing his stomach and intestinal tract, his appetite was very poor and the general languor was pronounced. The *diplopia had disappeared, but, as I now believe, entirely independent of the treatment.*

In September, 1898, there was an esophoria of 10 degrees. In November, 1898, diplopia was again in evidence for a few days, although general symptoms were better, knee-jerks both active, the upper lip moderately anesthetic, the hard palate more sensitive. The potassium iodid was discontinued and salol and bichlorid substituted. The patient now required a prism of 20 degrees, and one week later, a prism of 26 degrees.

Codein, strychnin and quinin were ordered by his general physician, Dr. Jurist. Tabes now seemed to offer the best explanation of the symptomatology. At his visits late in December, 1898, a slight defect in articulation was noted, with some recent shooting pains in the limbs, although these had not been frequent nor of great intensity.

A consultation with Dr. Mills was held early in January, 1899: in addition to the symptoms enumerated above, he examined for the tendon and muscle phenomena in the lower extremities, and found that the knee-jerks were present but slightly sluggish. The tendo-Achillis jerk was, however, absent on both sides. He had not then developed ataxia. The diagnosis of tabes was made, although his knee-jerks were retained, chiefly because the total syndrome could only be explained on this theory. The absent tendo Achillis jerk made Dr. Mills feel that this case was one in which the sacral cord had suffered more than the lumbar segments. From the diagnostic standpoint, the most important cases of tabes are those in which one or more of the well known symptoms like ataxia, lost knee-jerk, or lancinating pains are absent for a shorter or longer time. An important point to bear in mind; in a case like the one under discussion, is the possible development *of general paretic symptoms later in the history of the case.*

Dr. Mills prescribed iodid and hypophosphites. There was some improvement and exacerbation until May, 1899, when the diplopia was again very marked. This time he was placed on iodid of lithium and chlorid of gold and sodium. Because of disturbed digestion, the iodid had to be stopped, and the gold and sodium retained with a gratifying improvement in the diplopia, the esophoria in June being reduced to 6 degrees at 6 m.

In July, 1899, he was able to use his bicycle with comfort, his appetite was improved, he gained 10 pounds, and there was no doubling unless tired at night—esophoria, 5 degrees.

In the early fall, diplopia was again in evidence, convergence became very marked, anesthesia and numbness of the lips and palate increased, with a number of laryngeal crises, and a further study of the deep reflexes of the lower extremities, ankle and foot showed their entire absence.

A rest in the South for three months resulted in a further removal of the diplopia, and the general condition, up to the past February, *remained unchanged.*

In March the patient sailed for a year's trip abroad. He was desperately seasick while crossing, and wrote me from Heidelberg that the diplopia had again recurred.

The following points are especially noteworthy in connection with the study of the case I have cited: 1. In a period of two years, absolutely the only ocular manifestation was a series of paretic attacks of the left external rectus muscle, the duration of the paresis varying from a few weeks to about three months. 2. The retention, during almost the entire period of observation, of the knee-jerks. 3. The existence of various foci of degeneration, as especially illustrated in the comparatively early involvement of the sacral cord and the consequent loss of the deep reflexes of the lower extremities; the paretic ocular muscle, the numbness, the laryngeal crises. 4. Although a specific history was thought to be present, the antisyphilitic treatment was quite nugatory or possibly damaging, for the reason previously stated. 5. The therapy, aside from the stomach and intestinal requirements, that gave the best, although but palliative result, was chlorid of gold and sodium.

DISCUSSION.

DR. S. D. RISLEY, Philadelphia—Dr. Ring has honored me with a request to open the discussion on this very important topic, but I can not, in the very few moments allowed, enter into any extensive general consideration of tabes. A few years ago, through the courtesy of friends, I went through several general hospitals in Philadelphia and studied the ocular conditions in every case of tabes I could find. The result of those studies, I am sorry to say now, were never published, but left a very pronounced impression upon my own mind. In the first place, a very large proportion showed a greyness of the outer halves of the optic nerves, but in many instances this was not present until late in the disease. Another point that impressed itself on my mind was the abnormalities of ocular motility, which often came on very early in the disease. It is generally said that these ocular paralyses are transient. That is certainly so in a large number of cases, but there is a group like the one presented to-day in which it is not transient. I have never seen a case in which the external recti were involved that the paresis proved to be transient. The transient cases of paralysis were always of one of the vertically acting muscles or of the internal recti. The paralysis is often quite transient, lasting but a few hours or days. In this connection I recall the case of an eloquent clergyman who was to have been one of the speakers at the dedication of the Bartholdi fountain at the Centennial Exposition in Philadelphia, in 1876. He was sitting on the platform awaiting his turn to speak, when he suddenly became nauseated and giddy, and was compelled to leave the platform. He thought it was due to the heat, but from his lucid statement it appeared to be a plain case of diplopia due to a transient palsy of the internal rectus. The symptoms disappeared after a few hours, but occasionally afterward, he was annoyed by brief periods of disturbed vision which he learned to know were due to impaired muscular balance. I did not see him until 1881, when he was sent to me by the late Dr. William Pepper, because of this disturbance of vision. He then had, in the left eye, an absolute macular scotoma with a contracted field, and a distinctly grey outer half of the nerve. The patellar reflexes were impaired, but station was good. The disease slowly progressed until there was total atrophy of the optic nerve, and no perception of light. The right eye was healthy and vision normal; no contraction of the field and no scotoma. Perhaps six years later he came complaining of trouble with the other eye. I found here also a macular scotoma with the same appearances about the disc, and this also passed to complete blindness. His gait was now ataxic and he died a few years ago, twenty years after the transient attack of diplopia and fifteen after the commencing atrophy of the optic nerve on the left side, having been confined to his room for many years. The initial symptom in this case occurred in 1876, and for ten years afterward he pursued his professional calling and was called on for many public addresses besides, while during those ten years he could not be made to believe he was in any sense ill.

I wish to allude to one other point concerning the treatment. For many years I have been using bichlorid of mercury in these cases. I have one man who has been under my care since 1884, a novelist who has followed his calling without interruption, and is now, in addition, the editor of a literary publication, and has for sixteen years taken bichlorid of mercury internally, in doses anywhere from 1/100 gr. three or four times a day to 1/24 or even 1/12 gr., he regulating the doses himself up to the point of relief from the lightning pains. His reflexes are absent, his station impaired but variable, but at no time has he manifested any disturbances of ocular motility. He came under observation in 1884 for impaired vision. There was a central scotoma for red and some concentric contraction of the fields. He was an excessive smoker and the victim of irregular habits culminating in an occasional spree. When made to comprehend his danger, he corrected his habits in great measure, but the tabetic symptoms slowly advanced. The relief from pain secured by the corrosive sublimate is of great interest. The etiology, as we know, is obscure, but most observers regard it as due to syphilis. In one case under my care for about ten years, with paralysis of the externus, the patient believed that his disease was due to excessive venery. How correct his own view in this case was I do not know, but it was his firm conviction.

DR. JOHN E. WEEKS, New York City—I would like to suggest that in all probability this particular salt of mercury is not necessarily the only one that will produce amelioration of the painful symptoms in tabes, but that mercury in ointment, the simple metallic mercury, is sufficient in many cases. I have reference particularly to a case recently under observation, in which inunctions were used very frely, the patient being kept at the point of saturation for some time; the relief of pain, as well as the improvement in his general condition was extremely marked. The idea that tabes is a disease due to an affection of the peripheral neurons is perhaps completely established at the present time: the atrophy of the optic nerve is secondary to degeneration of the ganglion cells in the retina.

DR. L. WEBSTER FOX, Philadelphia—A man I had under observation some time ago, who had gone the rounds of the hospitals, told me the only relief he got was from excessive doses of whisky. I do not wish to encourage the drinking of whisky in such cases, but only mention this as one of the many remedies that have been applied to these cases.

DR. RING—Dr. Fox's suggestion confirms my opinion that some of these cases, even though they are specific, do not get relief from the use of antisyphilitic treatment, the lesion being rather a degenerative sequence of syphilis. It may be of interest, in closing, to note, from a letter I received from this patient the day before I left Philadelphia, that the patient has had another recurrence of the diplopia following a severe voyage and desperate seasickness.

THE AMOUNT OF MYOPIA CORRECTED BY REMOVAL OF THE CRYSTALLINE LENS.*

EDWARD JACKSON, M.D.

DENVER, COLO.

Despite the hundreds of reported cases, great uncertainty still remains as to the exact optical effect produced by removing the clear crystalline lens from a highly myopic eye. The great mass of these cases are so reported as not to throw any definite light on the optical questions involved. To point out what is our present knowledge of the subject, and to urge the reporting of more exact data regarding future cases are the purposes of this paper.

Myopia due to Excessive Corneal Curvature.—If a high myopia were due solely to excessive curvature of the cornea—the anteroposterior length of the eyeball and the refractive power of the lens being no greater than in the average emmetropic eye—the removal of the crystalline lens would cause substantially the same optical effect as it would in the emmetropic eye; that is, about 11 D. of change as measured at the cornea; or 12 to 13 D. as measured by a concave lens placed in the usual position for spectacle lenses.

Myopia due to Excessive Refractive Influence of Lens.—With a myopia due solely to the excessive refracwhy they do not mention it or say merely, as did Mauthner, that it is supposed to occur. As to the order of involvement of the muscles, Swanzy notes the externus as the one most affected, next the oculomotor, and next, probably, the levator palpebræ. Woinow and Berger also give the externus the first place, while Erb and Charcot assign it to the oculomotor. In Javal's experience, the levator was most frequently involved and, succeeding this, the internal rectus, the externus and superior oblique being very rarely diseased. Landolt, de Watteville and Von Graefe are in entire accord with Javal in this judgment, and oppose Berger in his statement that paralysis of the internus is comparatively infrequent.

---

* Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In the paretic or paralytic condition, the symptom of special annoyance is the diplopia. The cause of the paresis has been regarded as a vascular disturbance or a slight ependymitis in the nuclear region. It sometimes develops into a chronic ependymitis, with granular hyperplasia. They begin, says Pierret, as nuclear, extend toward the periphery, as descending neuritis, and here continue after the nuclear affection has disappeared.

Dejerine's examinations proved that not all ocular paralyses in tabes are of nuclear origin. The muscle involvement is seldom complete, and is limited usually to one eye. The complete and permanent paralysis of an isolated orbital muscle, occasionally noted in locomotor ataxia, is probably due, according to Swanzy, to a peripheral, rather than to a nuclear disease, but occasionally a well-marked muscular paralysis, affecting a number of muscles, occurs.

It is not possible to diagnose locomotor ataxia with certainty in a patient who shows only ocular symptoms, the diagnosis between this disease and insular sclerosis remaining doubtful until general symptoms develop.

The eye muscles paralyzed in tabes have in themselves nothing absolutely characteristic. The paralysis develops rapidly and usually disappears slowly. In cases of tabes that succeed syphilis, the lesion is not syphilitic in histologic character. In this sort of case, as well as in the type in which syphilis can be excluded, the disease is a degenerative one and rarely influenced by antisyphilitic treatment. It is to be regarded as a degenerative sequel of syphilis, rather than a true syphilitic disease. This view is in accord with the experience of Dr. Mills.

The case which has formed the basis of my brief study of paresis of the external recti, as symptomatic of irregular tabes, has been under observation since Feb. 13, 1897. The period during which organic symptoms of the spinal segments, or more properly, segments of the cerebrospinal system, have been carefully noted, has been two years, the only ocular manifestation having been recurring attacks of paresis of the left external rectus muscle.

The patient is a male, aged 30, with an unusually fine mental equipment, and at his initial visit was in perfect condition physically; married, with one (healthy) child. His mother, at an advanced age, has very severe asthma. The family history is otherwise good and, as bearing on his present condition, negative. At the period of his initial visit vision was reduced to 4/200 in each eye, refraction highly myopic and astigmatic, with huge characteristic crescents, the astigmatism being against the rule. There was no muscular abnormality, excepting an exophoria of .5 degree. With the appropriate correction, the vision equaled 20/25 in each eye.

Fifteen months later—May, 1898—the patient again reported, complaining of numbness of the lips, particularly the upper, with anesthesia of the roof of the mouth, some aching in and over the left eye, apparently more aggravated during periods of constipation, but no paresis of any external eye muscles or other distinctive eye symptoms. There was left hyperphoria of 2 degrees. Four days later the same vertical error and, in addition, an insufficiency of 10 degrees of the externi-esophoria. Three days later the esophoria had increased to 16 degrees, and double images had become almost constant, but distinctly more marked at the close of a busy day, as was also the anesthesia of the roof of the mouth.

Pupilary study, beyond the slightest sluggishness, showed no abnormality. The right knee reflex was slightly diminished, also the left. There was entire absence of any hemorrhage or splotches in the eye ground, and the form field—beyond a slight outer contraction—was normal.

Inclined, at this early period, to regard the case as probably specific in origin, I had a consultation with his family physician and friend, Dr. Louis Jurist, who remembered having treated him for a skin rash some years previously, which he regarded as specific. The patient stoutly denied the existence of any such condition, and no other symptoms, primary or secondary, were present. At my suggestion he was placed on mercurial inunctions, followed by iodids. At the end of about two months the diplopia had disappeared, but the remaining symptoms were about *in statu quo;* the treatment was demoralizing his stomach and intestinal tract, his appetite was very poor and the general languor was pronounced. The diplopia had disappeared, but, as I now believe, entirely independent of the treatment.

In September, 1898, there was an esophoria of 10 degrees. In November, 1898, diplopia was again in evidence for a few days, although general symptoms were better, knee-jerks both active, the upper lip moderately anesthetic, the hard palate more sensitive. The potassium iodid was discontinued and salol and bichlorid substituted. The patient now required a prism of 20 degrees, and one week later, a prism of 26 degrees.

Codein, strychnin and quinin were ordered by his general physician, Dr. Jurist. Tabes now seemed to offer the best explanation of the symptomatology. At his visits late in December, 1898, a slight defect in articulation was noted, with some recent shooting pains in the limbs, although these had not been frequent nor of great intensity.

A consultation with Dr. Mills was held early in January, 1899: in addition to the symptoms enumerated above, he examined for the tendon and muscle phenomena in the lower extremities, and found that the knee-jerks were present but slightly sluggish. The tendo-Achillis jerk was, however, absent on both sides. He had not then developed ataxia. The diagnosis of tabes was made, although his knee-jerks were retained, chiefly because the total syndrome could only be explained on this theory. The absent tendo Achillis jerk made Dr. Mills feel that this case was one in which the sacral cord had suffered more than the lumbar segments. From the diagnostic standpoint, the most important cases of tabes are those in which one or more of the well known symptoms like ataxia, lost knee-jerk, or lancinating pains are absent for a shorter or longer time. An important point to bear in mind, in a case like the one under discussion, is the possible development of general paretic symptoms later in the history of the case.

Dr. Mills prescribed iodid and hypophosphites. There was some improvement and exacerbation until May, 1899, when the diplopia was again very marked. This time he was placed on iodid of lithium and chlorid of gold and sodium. Because of disturbed digestion, the iodid had to be stopped, and the gold and sodium retained with a gratifying improvement in the diplopia, the esophoria in June being reduced to 6 degrees at 6 m.

In July, 1899, he was able to use his bicycle with comfort, his appetite was improved, he gained 10 pounds, and there was no doubling unless tired at night—esophoria, 5 degrees.

In the early fall, diplopia was again in evidence, convergence became very marked, anesthesia and numbness of the lips and palate increased, with a number of laryngeal crises, and a further study of the deep reflexes of the lower extremities, ankle and foot showed their entire absence.

A rest in the South for three months resulted in a further removal of the diplopia, and the general condition, up to the past February, remained unchanged.

In March the patient sailed for a year's trip abroad. He was desperately seasick while crossing, and wrote me from Heidelberg that the diplopia had again recurred.

The following points are especially noteworthy in connection with the study of the case I have cited: 1. In a period of two years, absolutely the only ocular manifestation was a series of paretic attacks of the left external rectus muscle, the duration of the paresis varying from a few weeks to about three months. 2. The retention, during almost the entire period of observation, of the knee-jerks. 3. The existence of various foci of degeneration, as especially illustrated in the comparatively early involvement of the sacral cord and the consequent loss of the deep reflexes of the lower extremities; the paretic ocular muscle, the numbness, the laryngeal crises. 4. Although a specific history was thought to be present, the antisyphilitic treatment was quite nugatory or possibly damaging, for the reason previously stated. 5. The therapy, aside from the stomach and intestinal requirements, that gave the best, although but palliative result, was chlorid of gold and sodium.

DISCUSSION.

Dr. S. D. Risley, Philadelphia—Dr. Ring has honored me with a request to open the discussion on this very important topic, but I can not, in the very few moments allowed, enter into any extensive general consideration of tabes. A few years ago, through the courtesy of friends, I went through several general hospitals in Philadelphia and studied the ocular conditions in every case of tabes I could find. The result of those studies, I am sorry to say now, were never published, but left a very pronounced impression upon my own mind. In the first place, a very large proportion showed a greyness of the outer halves of the optic nerves, but in many instances this was not present until late in the disease. Another point that impressed itself on my mind was the abnormalities of ocular motility, which often came on very early in the disease. It is generally said that these ocular paralyses are transient. That is certainly so in a large number of cases, but there is a group like the one presented to-day in which it is not transient. I have never seen a case in which the external recti were involved that the paresis proved to be transient. The transient cases of paralysis were always of one of the vertically acting muscles or of the internal recti. The paralysis is often quite transient, lasting but a few hours or days. In this connection I recall the case of an eloquent clergyman who was to have been one of the speakers at the dedication of the Bartholdi fountain at the Centennial Exposition in Philadelphia, in 1876. He was sitting on the platform awaiting his turn to speak, when he suddenly became nauseated and giddy, and was compelled to leave the platform. He thought it was due to the heat, but from his lucid statement it appeared to be a plain case of diplopia due to a transient palsy of the internal rectus. The symptoms disappeared after a few hours, but occasionally afterward, he was annoyed by brief periods of disturbed vision which he learned to know were due to impaired muscular balance. I did not see him until 1881, when he was sent to me by the late Dr. William Pepper, because of this disturbance of vision. He then had, in the left eye, an absolute macular scotoma with a contracted field, and a distinctly grey outer half of the nerve. The patellar reflexes were impaired, but station was good. The disease slowly progressed until there was total atrophy of the optic nerve, and no perception of light. The right eye was healthy and vision normal; no contraction of the field and no scotoma. Perhaps six years later he came complaining of trouble with the other eye. I found here also a macular scotoma with the same appearances about the disc, and this also passed to complete blindness. His gait was now ataxic and he died a few years ago, twenty years after the transient attack of diplopia and fifteen after the commencing atrophy of the optic nerve on the left side, having been confined to his room for many years. The initial symptom in this case occurred in 1876, and for ten years afterward he pursued his professional calling and was called on for many public addresses besides, while during those ten years he could not be made to believe he was in any sense ill.

I wish to allude to one other point concerning the treatment. For many years I have been using bichlorid of mercury in these cases. I have one man who has been under my care since 1884, a novelist who has followed his calling without interruption, and is now, in addition, the editor of a literary publication, and has for sixteen years taken bichlorid of mercury internally, in doses anywhere from 1/100 gr. three or four times a day to 1/24 or even 1/12 gr., he regulating the doses himself up to the point of relief from the lightning pains. His reflexes are absent, his station impaired but variable, but at no time has he manifested any disturbances of ocular motility. He came under observation in 1884 for impaired vision. There was a central scotoma for red and some concentric contraction of the fields. He was an excessive smoker and the victim of irregular habits culminating in an occasional spree. When made to comprehend his danger, he corrected his habits in great measure, but the tabetic symptoms slowly advanced. The relief from pain secured by the corrosive sublimate is of great interest. The etiology, as we know, is obscure, but most observers regard it as due to syphilis. In one case under my care for about ten years, with paralysis of the externus, the patient believed that his disease was due to excessive venery. How correct his own view in this case was I do not know, but it was his firm conviction.

Dr. John E. Weeks, New York City—I would like to suggest that in all probability this particular salt of mercury is not necessarily the only one that will produce amelioration of the painful symptoms in tabes, but that mercury in ointment, the simple metallic mercury, is sufficient in many cases. I have reference particularly to a case recently under observation, in which inunctions were used very frely, the patient being kept at the point of saturation for some time; the relief of pain, as well as the improvement in his general condition was extremely marked. The idea that tabes is a disease due to an affection of the peripheral neurons is perhaps completely established at the present time: the atrophy of the optic nerve is secondary to degeneration of the ganglion cells in the retina.

Dr. L. Webster Fox, Philadelphia—A man I had under observation some time ago, who had gone the rounds of the hospitals; told me the only relief he got was from excessive doses of whisky. I do not wish to encourage the drinking of whisky in such cases, but only mention this as one of the many remedies that have been applied to these cases.

Dr. Ring—Dr. Fox's suggestion confirms my opinion that some of these cases, even though they are specific, do not get relief from the use of antisyphilitic treatment, the lesion being rather a degenerative sequence of syphilis. It may be of interest, in closing, to note, from a letter I received from this patient the day before I left Philadelphia, that the patient has had another recurrence of the diplopia following a severe voyage and desperate seasickness.

THE AMOUNT OF MYOPIA CORRECTED BY REMOVAL OF THE CRYSTALLINE LENS.*

EDWARD JACKSON, M.D.
DENVER, COLO.

Despite the hundreds of reported cases, great uncertainty still remains as to the exact optical effect produced by removing the clear crystalline lens from a highly myopic eye. The great mass of these cases are so reported as not to throw any definite light on the optical questions involved. To point out what is our present knowledge of the subject, and to urge the reporting of more exact data regarding future cases are the purposes of this paper.

Myopia due to Excessive Corneal Curvature.—If a high myopia were due solely to excessive curvature of the cornea—the anteroposterior length of the eyeball and the refractive power of the lens being no greater than in the average emmetropic eye—the removal of the crystalline lens would cause substantially the same optical effect as it would in the emmetropic eye; that is, about 11 D. of change as measured at the cornea; or 12 to 13 D. as measured by a concave lens placed in the usual position for spectacle lenses.

Myopia due to Excessive Refractive Influence of Lens.—With a myopia due solely to the excessive refractive influence of the lens, whether from excessive curvature, high refractive index, displacement of the lens forward or all of these combined—the corneal curvature and anteroposterior axis remaining the same as for the emmetropic eye—the eye after removal of the lens would possess the same refraction as would a previously emmetropic eye after removal of the lens; that is, whatever the amount of previous myopia, the eye would be left hyperopic about 11 D. measured at the cornea, and would require for its correction a convex 10 D. lens placed in the usual position.

---

* Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Myopia due to Increased Length of Axis.—When myopia is due to increased length of the anteroposterior axis of the eyeball, the optical effect of removal of the crystalline lens, as measured in diopters, either at the cornea or at the usual position for correcting lenses, increases directly with the increase of the axis. The higher the myopia the greater the effect of removal of the crystalline lens. Yet as to the amount of myopia that should be just corrected by removal of the crystalline lens, as to the previous refraction of the eye which when rendered aphakic will become emmetropic, different writers are widely at variance.

My own approximate estimate[1] by means of the "dioptric eye," was 18 D.; Hirschberg's, by the rule[2] of finding the correction after operation, by subtracting half the myopia from + 10 D., is 20 D.; Otto's,[3] by calculation, 20.08; Hirschberg's, by calculation, 21; Weiland's,[4] by approximate calculation, 25.61; Percival's[5], by calculation, 25.85; Weiland's, by accurate calculation, 25.952. The last three are based on the schematic eye of Listing, with the dimensions assigned to it by Helmholtz, generally regarded as the most exact conception of the average refraction of the human eye.

Let us contrast the theoretic possibilities of the case. The myopia of an eye that will be rendered emmetropic by removal of the crystalline lens will be: For myopia due to corneal curvature, 13 D.; for axial myopia, 26 D.; for lens myopia of any amount the eye will never be left emmetropic, but will be made hyperopic, 10 D.

Finally we must compare with these theoretic possibilities the effects reported of removal of the crystalline lens in actual cases; although it must be noted that the majority of these reports show, upon the very face, that they are loose and inaccurate. Very few of them are based on full and carefully determined data. In not a half dozen cases out of the whole series are measurements of the corneal curvature mentioned. Cross[7] calls attention to the uncertainties attending determinations of high myopia by the common subjective methods, and states that he used skiascopy in some of his 48 cases. In only 3 out of 114 did Deutschman recognize any astigmatism prior to operation. Of course looseness and inaccuracy in the determination of the myopia before operating, greatly diminishes the value of such statistics; and absence of measurements of the corneal curvature makes them worthless for certain important purposes.

Still, it is worth while to compare these recorded results with those of theoretic investigations. I have tabulated the recorded results of 296 cases. The first column gives the diopters of myopia before operation; the second gives the theoretical change to be expected for axial myopia, according to Eperon,[8] the third gives the average change observed; the fourth the maximum and the fifth the minimum change reported; and the sixth column gives the number of cases of each degree of myopia included. The diopters of myopia or of change are averages of the two principal meridians, where astigmatism is reported.

Previous Myopia.	Theoretic Change.	Average Change.	Maximum Change.	Minimum Change.	Number of Cases.
10	14	16.60	19	15	5
11	14.64	16.67	19	13	6
12	15.2	16	18.50	14	12
13	15.67	17.2	19	15.5	24
14	16.3	17.14	19.50	14	37
15	17	17.15	21	12	28
16	17.5	17.70	24.50	13	58
17	18.23	19	22	16	14
18	18.8	19	24	15	38
19	19.36	18.50	20	16	6
20	20.10	19.81	24	16	32
21	.....	20.20	20	19	5
22	21.4	21.25	25.5	18	15
23	.....	21.67	26	19.5	6
24	.....	22.40	24	21	3
25	.....	23	23	23	1
26	.....	23	23	23	2
30	.....	27	28.5	26	3
35	.....	29	29	29	1

It is obvious that the number of cases on which the above table is based is insufficient to furnish accurate and reliable averages. Still, the table may be taken to indicate about what those averages will be. And it does bring out with certainty the wide range between the maximum and minimum effects that may be produced. Added numbers of cases can only separate the maximum and minimum more widely.

We must conclude from this table, that for a given amount of myopia the effect of removal of the crystalline lens may vary 10 D. or more. Such a variation is too great and too common to be explained as mere inaccuracy of observation. While the general trend of the figures indicate that a lengthened anteroposterior axis is the most important cause of very high myopia, variations of corneal curvature, or of lens refraction, or of both, are factors of practical importance. We never can predict with exactness the effect of an operation until these are taken into account.

One other point is that the calculations based on the Helmholtz values of the schematic eye indicate that 25 or 26 D. of axial myopia should be corrected by removal of the crystalline lens. The reported cases indicate about 20 D. Clearly, either the high myopias are usually partly curvature myopias, or some of the values assigned to the schematic eye are at fault. The careful measurement of the corneal curves in each case, both before and after operation, with the accurate determination of the refraction at both times, would go far toward settling this question.

After lens extraction the curves of the cornea, as measured by the ophthalmometer, continue to change for several weeks or months. It is the permanent form of the cornea that is of interest in this connection; and we can not set any definite time when the changes will cease. Still, after six months the change is slight, and after a year will rarely be of any importance. Some such time must be allowed to elapse before any reliable evidence can be afforded by a given case, as to the influence of the operation in checking the tendency of myopia to increase or in bringing about a decrease.

In all cases of lens extraction through a large corneal incision, there is for a time a bulging of the cornea causing temporary increase in the anteroposterior axis of the eyeball. This gradually diminishes with corresponding diminution in the refraction of the eye. This occurrence, which is a common sequel of such operations, seems not to have been taken into account in the reported cases. It is the probable explanation of the claim that removal of the crystalline lens tends to cause subsequent shortening of the anteroposterior axis.

In conclusion, let me urge both for the good of the individual patient, and for the advancement of our knowledge of the refraction of the eye, and of this operation, the more complete and exact study of the ocular refraction and the curvature of the cornea, both before and after the removal of the crystalline lens for high myopia.

ON CERTAIN CLINICAL FEATURES OF EPIDEMIC INFLUENZA.*

HOWARD S. ANDERS, A.M., M.D.
Clinical Instructor in Physical Diagnosis, Medico-Chirurgical College; Physician to the Samaritan Hospital.
PHILADELPHIA.

In its symptomatic manifestations influenza is the hysteria of epidemic disease. Its puzzling obscurities, unique development, grotesque variations, distressing complications, and surprising sequels, make it paradoxically a type of the atypical in the class of infectious diseases, as is its functional analogue among the neuroses. No tissue seems too hidden; no structure, too strong; no function, too staple; no organ, too resistant, nor organism too robust to escape its Briarean grip.

This introductory arraignment is not stated as a proposition for subsequent proof—that is hardly necessary in the presence of practitioners, most of whom have already made a similar induction—but simply as a potential head from which the octopus-like tentacles grow, reach out, suck and sap their victims in the many ways more specifically referred to in what follows. My observations and deductions are based upon an analysis of 128 cases of influenza.

Onset.—The type of onset most frequently met with in the epidemic just passed was a combination of the cerebrospinal and respiratory forms; for the first two or three days, however, the symptoms of the former element predominated over those of the latter. In cases characterized by severe head, back and limb pains, prostration was extreme for from five to seven days; while those in which the dry bronchial cough was most distressing were not nearly so prostrated; indeed, many such did not feel ill enough to remain in bed more than one or two days, if at all.

A special feature in the onset of a great number of cases was the early appearance of congestion and suffusion of the conjunctivæ, a feature which, it will be recollected, was very distinctive about the third week of December, 1889, when the first cases of the great pandemic then beginning here were rapidly increasing in number.

Fever.—The mild cases showed little or no rise in temperature; and in the cases of severe suffering the temperature rose above 103, and that only during the first two or three days of the disease; in two uncomplicated cases only did the fever reach 105, each case representing an extreme of life, one having occurred in a 14-month infant, and the other in a woman of 72 years. The fever declined usually by a rapid lysis lasting two or three days. Continued fever for ten days was observed in one case. Subnormal temperature was frequent during convalescence, associated with bradycardia. In several instances the thermometer registered a daily remission ranging between 95.4 and 97 for nearly a week.

Cerebrospinal System.—Of the 128 cases, 6 were affected with such specially severe pains in the loin nerves and muscles as to indicate a true lumbago, although general pains and aching were also present. Pain and soreness of the sternocleidomastoid and other neck muscles were frequently noticed in connection with influenzal sore throat. Cephalalgia of intense type was present in 7 cases, the pains having been of a constant, severe, throbbing nature, with occasional sharp neuralgic darts, particularly through the temples. In a few cases marked nuchal pains, similar to those of a malarial paroxysm, were met with. One woman suffered greatly for nearly forty-eight hours from burning pains in the front and outside of the left thigh. There were 9 cases of influenza characterized by special involvement of one or more intercostal nerves, principally around the lower half of the chest. So prominent were the pains here that one felt almost sure that pleuritis must be present, until careful physical examination and closer study of the behavior of the pains and of the course of the case gave negative results in that direction. Enteralgia was marked in one case. In this connection Franke[1] mentions having met with peripheral neuritis of the intercostal and abdominal nerves simulating pleuritis, pericarditis, gastric ulcer and appendicitis. He refers also to the occurrence of pain and tenderness on the sole of the foot in some recent cases of "grip," due to ostitis of the tarsal and metatarsal bones, or to inflammation of the plantar fascia. Not one of my cases was so affected. However, in a case of neuritis affecting the plantar nerves of the left foot, which, for a time, closely simulated metatarsalgia or Morton's painful affection of the foot, the moderate pain, tenderness and disability beginning early in December, 1899, became particularly severe and intractable during the height of the influenza epidemic in March and April last; since that time rapid subsidence of the symptoms has taken place. This case was both rheumatic and traumatic in origin, having resulted from a strained position of the foot on damp ground while playing golf, the patient having a history of rheumatic sciatica and myositis. In 3 instances otalgia was a marked symptom; in one case facial neuralgia on the left side was the prominent feature for the first two days of the "grip" attack. Only one case manifested extreme mental disorder; this took the form of an acute maniacal delirium lasting nearly three weeks. The patient, a woman aged 50, was stubbornly deluded with the idea that she would die, even when much improved physically, saying often day and night, "I'll never get well; I'll never get well." She was passing through the menopause, had suffered somewhat from insomnia and gastrointestinal indigestion with flatulence, and had an unfavorable family history; an uncle and two brothers had died insane, and another brother is on the verge of insanity with alcoholism. The patient's previous mental and physical balance and health—before the climacteric—was excellent, and at this writing—June 4, 1900—her equanimity is nearly restored. Spitzly[2] reported a case of maniacal excitement which began on the fourth day of an influenzal attack and lasted nearly a week, ending in complete recovery.

Conjunctivitis.—As mentioned before, this was a frequent concomitant of the influenza epidemic and, as well, early in the attack of a number of cases. In 13 I found the hyperemic and watery membranes and eye-lids markedly affected, besides 4 cases in which suppuration had set in. The most severe case of purulent conjunctivitis occurred in a retired merchant aged 72, who had been afflicted with chronic articular gout for about twelve years; a purulent bronchopneumonia was also associated with the influenza attack.

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Otitis Media Purulenta.—This was present in 2 cases: in one it appeared five days after the onset in an infant having a severe bronchitis at the same time; in the other, in a medical student, it terminated an attack of influenza which began one week after a sharp attack of follicular tonsillitis had subsided.

Faucial, Tonsillar and Pharyngeal Inflammation.—A great many cases of influenza began with moderate coryza and faucial or pharyngeal soreness. In fact, faucial redness was found to be an early objective symptom of considerable constancy and value in the diagnosis. In 12 cases only was there distinctly marked tonsillar inflammation—not follicular—associated with the acute stage of the disease.

Respiratory System.—Laryngitis was a prominent manifestation of la grippe in 7 of my cases. There was little or no fever at any time; and the general aching and depression were seldom present to a degree that required a stay in bed longer than one day. The onset was characterized by sudden huskiness of the voice, and, within twenty-four hours, speaking became a mere wheezy whisper. It may be worthy of special record that, by stethoscopic auscultation over the thyroid cartilages of the larynx, in every case, one or two high-pitched dry or sibilant râles were heard, and during expiration only. In one case of influenzal laryngitis the nervous depression, although slight, lasted a little over three weeks.

Bronchitis was more or less common in nearly all of the cases, but I have noted 23 in which this was especially severe. And yet, the almost total and continued absence of any physical sign—any interrupted respiratory murmur or dry or moist bronchial râles—makes one hesitate to call the cause of the distressing, irritating, and exhausting coughs and substernal sense of tightness and oppression a real bronchitis. Indeed, it seemed that the cough was due rather to bronchial nerve irritation—in view of the selective affinity for nervous tissue by the active bacilli or toxins of this disease—or to congestion of the mucous membrane, with scanty, tough exudation, if any at all.

Marked dyspnea was a feature in several cases without, however, any symptomatic or physical evidences of cardiac, pulmonary or renal complications to account for it; and hence the inference that it was purely nervous in origin is probably a fairly true one.

Bronchopneumonitis was associated with influenza in 5 cases, having developed within six or seven days after the first symptom of the "grip" attack. The only physical signs of diagnostic value were those elicited by auscultation; especially in children were palpation and percussion of no service, because of the thin, elastic chest-walls and normally exaggerated resonance as compared with adults, so that any relative dulness that the small area of catarrhal consolidation might produce was practically eclipsed by the surrounding resonance rendered all the deeper and louder in tone by the tympanitic quality resulting from the adjacent relaxed and congested lung tissue. One case, in a very old man of gouty habit, with a patch of consolidation about the size of a small orange below the left scapula, terminated in an abscess and final healing. Soft pleural friction sounds were heard over the area. Thick greenish-yellow pus was expectorated freely for two weeks.

Dry pleuritis over small areas in the postero-axillary region was associated with 5 cases of influenza. In 4 cases of pulmonary tuberculosis, the dry pleuritis over the seats of consolidation was distinctly aggravated, as regards pain, cough and pleural crepitation, during superadded attacks of la grippe.

Gastrointestinal System.—Anorexia was common in most cases, but in 4 instances the depression of function was so extreme as to be really quite distressing for two or three weeks. The tongue was heavily coated and flabby, as in cases of chronic gastric catarrh, and while nausea and vomiting were absent, the aversion to all food of even the most delicate and appetizing preparations and service was so extreme as to necessitate rectal feeding for a while. In 3 cases—all women—the attack of influenza produced such nervous irritability of the gullet and stomach that the taking of liquid, soft or solid food, gave rise to immediate painful oppression and efforts at eructation or regurgitation back of the precordial and epigastric regions, due most likely to cardiospasm and pyloro-spasm. Flatulence and sluggishness of the bowels were present in a few cases otherwise normal in function. In 2 instances deficiency of liver action was pronounced, as shown in pasty, clay-colored stools, although jaundice was not evident.

Cardiovascular System.—In 3 severe or fulminant cases, two of which were in children, acute dilatation of the heart[3] was demonstrable by percussion, with diffuse, tumultuous ventricular impulse, and soft, short, systolic, blowing murmurs of relative insufficiency at the auriculo-ventricular orifices. These physical signs disappeared completely in convalescence. Tachycardia, with a pulse-rate of 142, though not much out of ratio with the temperature, namely, 105 F., occurred in a woman of 74 years of age. Bradycardia, however, was a remarkably frequent accompaniment of influenza recently during the convalescent period. This was especially noted in 13 cases, all adults with the exception of a girl of 11 years, who had a very mild attack; after defervesence, which occurred the third day, her pulse-rate varied between 56 and 65 for several days. In the other instances, abnormally infrequent pulse-rates varying between 44 and 60, and lasting from three to seven days was the usual occurrence. Nervous depression and subnormal temperature were often associated, as observed also by Byrne.[4] From confirmatory conversations with a number of practitioners it would seem that bradycardia during convalescence has been a marked feature in recent cases of influenza. Painful, excessive throbbing of the abdominal aorta was a prominent symptom in one young woman of hysterical tendency.

Vasomotor disturbance, in the form of greatly exaggerated and depressing flushes, was a feature throughout the course of the attack in three women passing through the climacteric. The pulse was peculiarly irregular as to rhythm and volume, along with occasional intermittency and persistent compressibility in 7 cases convalescing from "grip."

Influenzal Nephritis.—There were 2 cases of acute nephritis, from the causation of which everything could be excluded except influenza. Both patients were males: one aged 38, the other 18 years—seen with Dr. T. V. Crandall. The former had had a chancre, and had been a heavy drinker of alcoholics. The onset in both cases was sudden and characterized by the general pains and febrile disturbances so common, followed, in a few days, by a puffiness of beginning dropsy. Albuminuria was copious, one-third by volume in the older man, and a trifle over one-half in the other; the tube-casts were more abundant in the urine of the younger man, and were covered with renal cells and leucocytes, but later became granular. The older—syphilitic—patient died in uremic delirium; the younger had extreme anasarca, but is now on a fair way to recovery, with free urine of 1018 sp. gr., only an occasional cast and, as yet, no distinct cardiovascular changes.

Herpes labialis was observed in 30 per cent. of the cases; but no skin eruptions similar to scarlatina or measles, as reported by Herman,[3] were witnessed by me.

Complications.—There were 2 cases of influenza which, during the decline of the fever, but before the normal was reached, were complicated with lobar pneumonitis, one in the right, the other in the left lower lobes, with pronounced pleuritis at the same time. Both cases ended in pulmonary abscesses. One patient was a boilermaker, recovering in three weeks; the other was a colored sexton with a tubercular family history, and is now—June 4—in his fourth week of typhoid fever with the abscess cavity gravely retarding his chances of recovery.

Nephritis as a complication occurred in one case, a young schoolmistress, while suffering from a recurrent and fatal attack of "grip" during the second week of April. Her first attack, from which she recovered fairly well, lasted throughout the last week in January and the first two weeks in February, and was complicated also with extensive right-sided fibrinous pleuritis. It should be stated, too, that she had had chronic rheumatic endocarditis with mitral insufficiency and cardiac hypertrophy for twelve years.

Peripheral neuritis complicated 6 cases; in 2 the shoulder was affected. There were occasional burning pains, increased on motion of the deltoid and triceps, felt in those muscles, and passed along the course of the circumflex nerve, and of the musculospiral nerve at the insertion of the deltoid tendon, but not below the elbow. In 2 cases the neuritis was limited to the antero-external surface of the thigh—anterior crural nerve—and in two others, to the lower part of the leg, coursing especially behind, one the external, the other the internal malleolus, and over the instep, apparently quite superficial. These neurites developed usually during the beginning of the subsidence of the most acute symptoms and lasted from three weeks to two months. Paresthesias and slight paresis were noted, but no palsies.

Upon other diseased conditions the complicating effect of influenza was always varied, sometimes interesting and seldom absolutely negative. It was my experience, however, that whereas superadded influenza was fatal in but one instance—that one of chronic endocarditis previously referred to—the fatalities were more frequent in which influenza was itself complicated with some other affection. In a case of gastric ulcer in which blood was vomited copiously several times, the only effects were elevation of temperature, moderate bronchitis, and slight delirium for six days. In 2 cases of emphysema the chronic bronchitis was very much aggravated, the sputum became purulent and viscid, and the cough distressingly hard and weakening to the body. Cardiac dilatation and dyspnea were threatening in one case. Four cases of dry tubercular pleuritis were marked by pain, cough and increased friction murmur. An aged Jewess, with kyphoscolitic chest, chronic adhesive pleuritis and chronic bronchitis with emphysema, suffered great intensification of cough and dyspnea; the bronchitis became purulent, and fever and marked prostration ensued. In 2 cases subject to asthmatic attacks for years, the effect of influenza was to develop these attacks with intensity, and in both cases to give rise to purulent bronchitis. One of the patients had had hay asthma, coming on late in August, for many years, never at any other time, but said he suffered the same during his "grip" attack. Three cases of chronic valvular endocarditis affected with la grippe showed some cardiac arrhythmia and dyspnea. A walking case of pernicious anemia manifested only irritative dry tracheobronchial cough and increased weakness and dyspnea, and recovered nicely within ten days. In a case of large uterine myofibroma there were several attacks of fainting and increased uterine pains and a hemorrhage. The pains and after-depression in two cases of dysmenorrhea were considerably increased during the influenzal attacks. A woman of 56 years, of lithemic habit, who had been under treatment for neurasthenia for three months, was seized with an attack of influenza in the middle of April, while convalescing, and suffered great physical prostration and considerable cardiac irregularity for two weeks.

I hesitate to do more than mention that two cases of tertian intermittent malarial fever came under my care during the height of the "grip" epidemic; for, although no estivo-autumnal parasites were found in the blood of either patient—only the tertian hyalin and pigmented forms—I know of no data which would justify the claim that influenza is a predisposing cause of malarial attacks, even when so exceptionally prevalent during a season characterized by the recurrence of plasmodial activity in persons having had one series of paroxysms, as occurred in both of these cases last autumn; still it may not be altogether a hypothetic blunder to assert the possibility, at least, of such an etiologic relationship.

Recurrences.—There were four persons in whom second attacks of influenza were experienced after complete recovery from first attacks—hence, not relapses—after intervals varying from three to six weeks. Two were primary cases of pulmonary tuberculosis, one was a case of chronic valvular endocarditis—mitral—and one a woman at the menopause.

Sequels.—The following were observed: Unilateral sweating of the right side of the face and neck only, in a man aged 42; this symptom was noticed first two weeks after convalescence, lasted six weeks and disappeared unassisted as suddenly as it came on. Phlyctenular keratitis occurred two weeks after an attack of influenza in a negro boy 3 years of age, with a moderate degree of rickets. Erysipelas of the face and neck followed one week after a "grip" attack in a middle-aged woman, and terminated in an egg-sized abscess at the base of the left posterior anatomical triangle of the neck—inner portion of supraclavicular fossa—with recovery after incision and drainage. Melancholic depression lasting nearly two months followed a severe seizure in a woman aged 52, in the climacteric. Total deafness resulted in a girl of 3 years, who had severe head pains and delirium for one week. Paraparesis lasting several weeks was present also, but cleared up completely. Neuritis in the left shoulder in 1 case; and marked physical prostration and lack of ambition to resume any work whatsoever for some time after convalescence was established, were common to many patients.

Discrimination from other Affections.—It is not my purpose to enter into any details concerning the diagnosis or differentiation of influenza from other diseases. But closely woven with the warp threads of the clinical features previously outlined are the woof threads of diagnosis shuttled to and fro often in the judgment until the morbid design is complete, true, well-defined, substantial and therapeutically suggestive. So that, it may suffice to mention merely those affections that, in my experience, entered into the question of diagnosis. Thus, the symptoms of onset and development not infrequently made it necessary to decide upon influenza by the exclusion of the following diseases, principally: Acute muscular rheumatism or myositis, follicular tonsillitis, measles—in children, prior to the skin eruption and in the absence of Koplik's spots—intermittent malarial fever, cerebrospinal meningitis and typhoid fever—in lingering febrile cases.

In conclusion, among certain reflections that may be expressed based upon a study of some of the clinical and epidemiologic characters of influenza recently prevalent, are the following:

1. The disease has a ferret-like selection for "weak spots"; for the defective strands in the systemic rope, and especially for nerve tissue. Huchard[6] believes that the frequent pulmonary congestions met with indicated lower arterial pressure due to paresis of the vagus and diminished elasticity of the pulmonary vesicles.

2. The prominence of suppurative complications. Reading the recent classical Wesley M. Carpenter Lecture, by Dr. F. A. Packard, on "Infection through the Tonsils," makes one alert to the probability of the tonsils being gateways for the entrance of pus staphylococci and streptococci, as well as the bacilli of Pfeiffer. Congestive redness of the fauces appearing a day or two before the attack has been testified to by a number of careful observers. Huchard refers to the seriousness of secondary infection induced even in mild or attenuated forms—of influenza—by lowering the resistance and exalting, seemingly, the virulence of the ordinarily harmless bacteria of the body. It may be well, as Cotton suggests, that the intractable cases of la grippe are due really more to a streptococcus or staphylococcus infection, similar to the various resulting suppurative complications in pneumonitis, tuberculosis, scarlatina, pertussis, diphtheria, tonsillitis, and so on.

3. The relation of seasonal and meteorologic conditions to the prevalence of influenza and certain complications, as pleuritis, pneumonitis, neuritis and tonsillitis: The height of the severity of the "grip" epidemic was unusually late in coming this year—1899-1900—last year having been more of a normal seasonal "grip" year, the height lasting about seven weeks, beginning in the first week in December, 1898. As my notes show, there was a progressive increase in the number of cases of influenza from late in December, 1899, till April, 1900, the climax of the recent epidemic occurring during the six weeks from the middle of March to the end of April. My influenza cases numbered 5 in December, 12 in January, 22 in February, 35 in March, 47 in April, and 7 in May, 1900.

Now, as shown in a paper read by me in May, 1899, before the American Climatological Association,[7] influenzal outbursts are preceded by relatively warm, moist, and calm weather, but prevail with the onset of cold, clear, dry and windy weather, when the meteorologic data show an abnormal increase of the barometric pressure, lower temperature, abnormal temperature ranges and diminished equability, lower percentage of relative humidity, and increased prevalence of north and northwest winds. These observations I was able to confirm during the recent epidemic in connection with practically all of my case groups.

The meteorologic conditions favorable to the epidemicity of influenza prevailed at a time when the respiratory complications noted are usually favored, also, as independent affections, that is, after a remarkably warm and mild breeding December we had a remarkably late and cold spring, a season when the imprudent and impatient expose themselves too much and clothe themselves too little; insistently and recklessly making a fetich of a date or a festival to change their attire instead of sensibly adapting themselves to the axiom that they can not change the weather—hence the anginas, pleurites, pneumonites and neurites.

SURGICAL CIRCUMCISION.*

FERD. C. VALENTINE, M.D.

Professor of Genito-Urinary Diseases, New York School of Clinical Medicine; Genito-Urinary Surgeon, West Side German Dispensary; Genito-Urinary Consultant to the Metropolitan Hospital and Dispensary, to the United Hebrew Charities, Etc.

NEW YORK CITY.

It would be a work of supererogation to recite here the indications for removal of the prepuce; your specialty has made them an every-day occurrence through the whole gamut, from those immensely elongated foreskins with adhesions, concretions of urinary salts and smega, to the barely enlarged fold which causes no perceptible local disturbance and yet provokes most serious reflex conditions. I believe that my experience does not differ from that of other genito-urinary specialists, who are often called in by pediatrists or general practitioners to operate, and afterward learn that the removal of an almost normal foreskin was followed by cessation of enuresis, infantile convulsions, or glycosuria that had resisted other treatment.

How should circumcision be performed, and who should perform it? The preparation of the field of operation is naturally the same as that employed for any other surgical procedure, and the details and precision to be observed are necessarily the same.

Ordinary humanitarian sentiment prevents consideration of circumcision without anesthesia. It is perfectly true that millions of infants have been circumcised while entirely conscious, and no subsequent evil has befallen them; I do not believe, however, that any physician would rend a mother's heart by so torturing her babe. It is specious to hold that an infant's sensibilities are not sufficiently developed to permit it to perceive pain. If so, why does the infant cry when a maladjusted pin pricks it, or when its delicate skin is irritated by a badly folded or moistened diaper? Is it logical to assume that its shrieks of agony, when the foreskin is cut or torn off, are but reflex?

The choice between local or general anesthesia is necessarily governed by the age and condition of the patient. As a rule, general anesthesia should be employed in all children under the fifth year, provided no cardiac or pulmonary condition prohibits. General anesthesia too may be necessary in older children, whose mothers have striven to render them unfit for the battle of life by pampering them into milk-sops, or by convincing them that they are not born to suffer even the slightest inconvenience under any circumstances.

---

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Those brave little fellows whose mothers reared them properly in the just pride of giving *men* to the nation, are easy subjects of local anesthesia when circumcision is required. Some of these will insist upon being so placed that they can see every step of the operation and ask numerous amusing questions while it is being performed.

When deliberately done, the operation requires but a short time; the few instruments for the purpose are in every pocket-case. When carefully performed, under strict aseptic precautions, it leaves, within four to seven days, a union of skin and mucous membrane as perfect as if the patient had been born without a foreskin.[1]

Simple as is the technique of this circumcision, it in great part answers the question, "Who shall perform circumcision? We might stretch a point in this regard when viewed as a religious rite, if those who perform it had received the instruction to do a surgical operation in a surgical manner. Considering the origin of the operation in detail would lead us into the domain of theology, which we have as little ability to invade as have non-medical men to perform surgical operations. But we may recall that when Moses laid down the law of circumcision the priests were not only theologians, but law-givers and physicians as well. Five thousand years ago diseases were necessarily treated and operations performed in the light of the then existing knowledge. The extraordinary vital resistance of the races and of individuals who are circumcised may account for the wonderful escape from infection, which the majority of infants undergo. The Mohelim or Mauhelim in different regions perform the operation differently. All grades of uncleanliness are common. Some circumcisers suck blood from the cut; no one is deputized to ascertain that the operator (sic) is free from tuberculosis, syphilis, carious teeth, or even that he has a clean mouth with which to perform this filthy act. Others squirt a mouthful of wine or vinegar over the wound from an equally unexamined mouth. Some, it is true, have a very neat set of instruments for performing the operation, but none of them have as much as a bit of sterilized catgut to ligate the artery of the frenum, should it be cut. Others tear the prepuce with the thumb-nail, which is kept long for the purpose. The fact that finger-nails can not be kept aseptic suffices to denounce this method.

It would be un-American to deny any one the performance of an act which his religion demands. But when this act entails a surgical procedure upon a defenseless babe, the safeguards that should be placed around it furnish a question that jurists may well consider. Sociologists and political economists, too, might well investigate whether the risks of spreading syphilis, tuberculosis, erysipelas and other diseases by non-professional operators outweighs any fancied encroachment upon the rights of the individual. A glance at text-books on law teaches that even the unborn have rights; has not the child a week old an inherent right to protection from infection? Has not the public a perfect right to protection from the spread of disease? Does not the babe when infected with a communicable disease become a menace to the public?

Last year France enacted a law forbidding circumcision performed otherwise than in the presence of a physician. This was a step toward the proper end, but it can not prove as effective as might be desired; operators who must invariably expect asepsis of those who aid them know too well from sad experience the result of placing too much confidence in them. Unfortunately, the French law alluded to became effective at a time when our sister republic disgraced herself by a wave of irreligious persecution. The purpose of the law would then necessarily be misunderstood by the ignorant.

It is far from me to inveigh against circumcision of infants. To do so would be to defy the experience of all practitioners and particularly that of genito-urinary specialists. It would be folly to assert that the Jews of to-day are more moral than their uncircumcised brethren; the fact, however, remains that numerically those circumcised in infancy occupy less of a space in the annals of venereal diseases than do others.

While these considerations could be extended almost throughout the whole domain of medicine, I think enough has been said to ask your discussion of the following

1. Circumcision is a surgical operation, requiring all the precautions of asepsis and surgical technique, without which it is a danger to the individual and to the community.
2. Circumcision of infants, especially when the prepuce is large, contracted, adherent or deformed, is a benefit to the individual and a protection to the community.
3. The rights of individuals to the free exercise of religious liberty would be in no wise infringed if the operation of circumcision were performed by physicians.
4. The state should protect future generations by requiring that circumcision be performed by physicians.
5. If, for the sake of religious sentiment, devout Jews desire to have their babes circumcised by none but Jews, there are many Jewish physicians who could become Mohelim, so that while performing the religious rite they may conduct it as modern aseptic surgery demands.

31 West 61st Street.

DISCUSSION.

DR. LOUIS FISCHER, New York City—I would like to ask the author the after-treatment of circumcision—whether he uses merely a dry gauze dressing, a dusting powder, or what?

DR. EDWIN ROSENTHAL, Philadelphia—I would like to know whether Dr. Valentine advocates—in infants 1 or 2 days old having an impervious meatus—the use of the same technique? I have never known the professional circumciser to use any sutures, simply using lint. Does Dr. Valentine advocate the use of sutures and the same technique in the very young infant as in the adult? I would also like to ask whether he advocates the performance of circumcision from a purely hygienic standpoint, even in persons in whom there is no special indication?

DR. F. C. VALENTINE, New York City—I resort to no after-treatment. Inasmuch as the gauze retains the mucous membrane and skin together, nothing more is required. The slight oozing of blood which follows the coaptation of the lips of the wound takes place into the gauze itself, thus completing the adjustment and retention of the parts *in situ*. It forms a hard ring which drops off in from four to seven days, leaving no evidence of circumcision. I think in an infant of a day or two, with merely a tight and not large foreskin, I would content myself with simply snipping the prepuce, because usually when a child is relieved so early there is absorption of the dependent foreskin so that barely any deformity remains. On the other hand, if there are adhesions of the mucosa to the glans, I would certainly remove the entire foreskin for fear of a return of the adhesions. The desirability of circumcision is too large a subject for discussion at this time, but it is generally believed that fewer Jews and circumcised Mohammedans come to the genito-urinary specialist for the treatment of venereal disease than other nationalities. I say that they are comparatively rare, and by that I mean that perhaps in an average of say fifty cases daily I see four or five Jews. In southern Russia there is a sect of Jews who do not practice circumcision, and I am told that among them venereal disease is just as frequent as among the uncircumcised of other faiths. We hear considerable of making the toilet of the prepuce, yet it will often be found very filthy in men who are singularly clean about the rest of their person. I am not prepared just yet to advocate universal circumcision.

---

[1] The complete technique of painless circumcision of infants and adults is fully detailed on pages 90 to 101 of "The Irrigation Treatment of Gonorrhea, Its Complications and Sequelæ." Wm. Wood & Co., New York, 1900.

Dr. Fischer—I saw a secondary hemorrhage following on the second day after a surgical—not a ritual—circumcision. It was not a case of hemophilia. I should like to know the after-treatment for the unusual, not simply for the normal, cases.

Dr. Valentine—It is inconceivable to me how secondary hemorrhage can occur except in cases of hemophilia. It is a singular thing, however, that hemophilia occurs more frequently among the Hebrews than in any other race. I must admit I have seen secondary hemorrhage follow ritual circumcision. Here, torsion or ligation has been required. Uncleanly people sometimes allow the circumcision wound to become dirty and infected. By the technique alluded to in my paper the parts are protected from infection, though before adopting this method I did occasionally see these cases. I saw one case of infection after circumcision by the method described in a case which had been operated on by a beginner. Examination showed a stitch abscess from unclean catgut, and a neglect of proper precautions at the time of operating. These accidents should not occur. I have never performed circumcision upon a hemophile, but should I do so the chances are that I would try the effect of suprarenal extract. I should also treat the hemorrhage on general surgical principles. Sometimes in performing circumcision a vein is cut, with resultant hematoma. Even a very small hematoma can cause considerable fever—perhaps even as high as 104.5. In one such case all that was necessary was to curette out the hematoma and re-dress the parts. Within an hour or less the temperature had dropped to the normal.

TREATMENT OF LARYNGEAL TUBERCULOSIS AT THE MONTEFIORE HOME FOR CHRONIC INVALIDS (N. Y.)*

W. FREUDENTHAL, M. D.
NEW YORK CITY.

One of the most difficult chapters in the treatment of the upper air-passages is the management and treatment of laryngeal tuberculosis. In fact, to the hospital physician this has been one of the most disagreeable tasks possible. To see these most miserable of sufferers live for months, or even years, with constantly increasing pain, for whom even the swallowing of their own saliva is a dreaded effort, has been an occurrence of every day; and we, as physicians, have been as a rule practically helpless in combatting this disease. Morphin, internally and locally, quickly reached its effectiveness in most cases, and for many patients the cocain spray is extremely disagreeable. For the last ten years I have had to attend to these patients at the Montefiore Home, where we have sometimes as many as twenty or thirty suffering from laryngeal tuberculosis in every stage possible. That under the above condition of our comparative helplessness it was not pleasant to treat these patients and see them suffer pain constantly, with occasional relief lasting half an hour or a little longer, every one will admit. Luckily things have changed in the last few years, and I confess that nowadays it is a pleasure to treat such patients. They look happier, they feel better, can swallow much better, and last, but not least, they are anxious to receive the treatment, while formerly they not infrequently tried to avoid it. All these facts have also been noticed by other physicians who have seen the patients at the above institution.

However, before I describe the methods applied nowadays, I will say that there is a stage foregoing the formation of tubercles and ulcerations in the larynx. Such conditions we can see quite often in an institution like the above one, where there are besides the many consumptives just as many afflicted with some form of nervous or other troubles. These conditions in the larynx, which I might sum up under the name of

"PRETUBERCULOUS LARYNGITIS,"

have to be treated with as much care as the outspoken tuberculous affections of the larynx. Of course, this is done with greater ease in a closed hospital with mixed patients—i. e., tuberculous and non-tuberculous—where every one showing any of these symptoms is considered suspicious and treated accordingly. But with people who already have signs of tuberculosis of the lungs, and manifest some catarrhal symptoms in the larynx, this can and ought always to be done in private or dispensary practice as well. If in this stage a patient is treated conscientiously I am convinced that in many cases an outbreak of tuberculosis of the lungs can be avoided.

The symptoms of this stage are anemia, hyperemia and swelling. In making these divisions I agree perfectly with Otto Ringk,[1] when he says: "The treatment of this first stage is to be considered according to whether we have to deal with anemic or with hyperemic mucous membrane. The strictest differentiation between the medicaments after this point has been decided assures the possibility of success. The former naturally will need more irritant drugs than the latter.

In the anemic stage I have found the following to be of service: insufflations of zinc sozoiodol with sugar-of-milk, with applications of nitrate of silver in 3 per cent. solutions, liquor ferri sesquichlor. (1 to 30) and balsam of Peru with spir. vini rectif. I have not risked applying any strong astringents or caustics for fear that we might get not only a hyperemia, but as it occurred in a case of Ringk's, an edema of the entire mucous membrane of the larynx. I need not remark that such an accident is the last to be desired, and that we have to be on our guard in making applications.

In the hyperemic stage I have used, with here and there remarkably good results, the following solution: Creosote, 5; spir. vini, 10; glycerin, 50. (The creosote can be used even stronger; see Schech.) Applications of tannin, alum and other astringents have also been used with benefit. That different inhalations ought to be used besides this treatment, and that especially at this stage any catarrhal condition of the nose or throat ought to be looked after very carefully, I will only mention in passing.

After ten years' experience at the Montefiore Home, I am convinced that there exists such a pretuberculous laryngitis, and that it can be treated successfully in a number of cases, thus preventing the real outbreak of tuberculosis in the larynx. Once an erosion or an ulceration is to be seen in the larynx, we treat the patient as tuberculous. This leads us to tuberculous laryngitis itself, and we see here, as is generally conceded, four different forms, viz.: 1, the tuberculous infiltration; 2, the tuberculous ulceration; 3, the tuberculous tumor, and 4, miliary tuberculosis of the larynx. I do not wish to go into details as to the pathologic anatomy of these conditions. Allow me to remark only that I have repeatedly seen, and here I agree with B. Fränkel, miliary tubercles in the larynx. Virchow even recommends the larynx to all those who want to study the true tubercle. These tubercles, however, are located very superficially and break down at a very early stage, leaving a small shallow ulcer. This is the reason that we so often see ulcerations but not miliary tubercles. At the Montefiore Home, where I examine the patients and watch them at a time when they show no symptoms of tuberculosis and complain only, perhaps, of a little scratching in the throat, I repeatedly saw, as I have said, some miliary tubercles.

---

* Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Monatsschr. f. Ohrenheilkunde, p. 180, 1889.

That in the general treatment of laryngeal tuberculosis pure air is as essential as anything else, goes without saying, and this fact has been recognized by the directors of the Home. Upper Broadway—near One Hundred and Fortieth Street—where this institution is located, has become a great thoroughfare, with entirely too much dust and traffic for consumptives. Therefore, a new home with all modern improvements is being erected in the country, at Bedford Station, N. Y.; and it is the purpose to gradually remove all the consumptives to this country place. This plan will surely bear excellent results in the near future. I need not mention that general treatment is carried out, including hydrotherapy, rest-cure, etc. A great problem for us still is how to keep all these patients occupied, but I hope we shall come nearer the solution of this when all consumptives are housed in the country.

LOCAL TREATMENT.

We now come to the most important point, the local treatment. The majority of our patients are in an advanced stage, and the treatment is thus so much more difficult than it is in many other institutions. At one time the application of different powders was very much in vogue. The most important of these, which still are popular to a certain degree, are boric acid, iodol, europhen, dermatol, aristol and pyoctanin. The latter is recommended by Bresgen, Rosenberg, Schech and others.

More important were the fluids used for direct application, and there is hardly any new or old drug that has not been recommended. The iodoform ether solution, which at one time could be seen in almost every clinic in the United States, is now very little used; Rosenberg's menthol with oil, carbolated glycerin, resorcin, balsam of Peru with collodion, the phenolum sulforicinicum, the injections of creosote and orthochlorophenol in glycerin, all have their followers, and have been applied with some satisfaction in a certain number of cases.

Lactic Acid Treatment.—The remedy par excellence, which for the last ten or twelve years has predominated over all, is lactic acid. I can speak with a certain authority about lactic acid, as I witnessed the very first experiments made in Berlin in 1885, by Professor Kráuse, and followed up some of these cases until their death. Since 1885 I have used lactic acid constantly. I know its advantages and disadvantages. We had seen tuberculous ulcers heal under nitrate of silver, under zinc chlorate, and other astringents, but it was claimed that the proportion was larger under lactic acid. There was some truth in this assertion, and I myself applied lactic acid during all that time, merely for want of something better, for I knew how many patients dreaded these applications—the pain, which sometimes lasted from ten to twenty hours after lactic acid had been rubbed into the ulcerations, was terrible to them, and others again feared the spasm of the glottis more than their usual pain. In a dispensary, where consumptives come and go, we do not notice how many stay away from such treatment, and judge only from those who remain. It is different in a sanatorium where the same patients are seen constantly, and I know quite a number who used all kinds of excuses only to stay away from the lactic acid treatment. It is different now. Since new drugs have given us the ability of making these people comfortable, they anxiously wait for treatment, and I have seldom known any one to miss it voluntarily.

Menthol-Orthoform Emulsion Treatment.—The way we proceed is the following: We generally cleanse the larynx, if this be necessary, with any indifferent spray, or swab it with cotton, etc. This is advisable also when there are secretions below the larynx in the trachea and down to the bifurcation. This previous cleansing makes the patients cough up the greater part or all of this secretion, and they can retain the drugs better. Whether these drugs do not in this way reach some ulcerations in the trachea which can not be seen by laryngoscopic examination, is a question which I should not like to decide here. It is, however, conceivable that fluids especially run down the trachea and gradually reach deeper ulcerations in the trachea.

After this cleansing a powder consisting of saccharated suprarenal gland—about 3 to 6 grains—is insufflated into the larynx mostly, on to the ulcerations. I do this in the beginning of the treatment, when I do not know the toleration of the patient, for the following drugs. But now it seems to me almost rational to use it in all cases of dysphagia, as it helps to prolong the local anesthesia. I have entirely abandoned the use of cocain for these cases, and this for several reasons: 1. The paresthesia following the application of cocain is very disagreeable to many patients. 2. It undoubtedly affects the heart in some cases. 3. The solution decomposes quickly—this holds good for all cases. The powdered suprarenal gland has no toxic effect if applied in this manner; it does not produce the paresthesia, but on the contrary, within one-half to one minute, a pleasant cooling sensation sets in, and it does not decompose readily in this powdered form.

The next step is the application of my menthol-orthoform emulsion. I have been using this emulsion for over two years, and the more I use it the better I like it. Carl Kassel was the first one to use an emulsion with olive-oil. He says[2] that my emulsion is a great improvement on his, but that a bad taste persists after its use. I have never heard any complaint of this from any patient, nor from any other physician, and I think the Doctor is mistaken in this respect. If anything, the taste of the menthol-orthoform emulsion is pleasant.

There can be no doubt that the anesthetic properties of the orthoform on the mucous membranes of the ulcerated larynx are of immense value. And there is no longer any question that by means of the application of orthoform we are able to relieve pain, and cause a disappearance of the difficulty in swallowing, lasting, according to my present experience, from a few hours to three, four, or even five days. These patients are not only able to take nourishment readily, and thereby are placed in a better position for a possible cure, but in favorable cases we completely remove the pain.

In all irritations of the larynx menthol is of excellent service. No doubt the good results obtained some fifteen years ago, by my friend Prof. A. Rosenberg, of Berlin, with injections of menthol with oil, were due to this fact. It relieves the cough and with this much of the secretion. This is the reason I added menthol to the above emulsion. I use the following:

℞.	Menthol	1, 5, 10 or 15	
	Ol. amygdal. dulc	30	
	Vitelli ovorum	25	
	Orthoformi	12	5
	Aquæ dest. q. s. ad	100	
Ft. emulsio.			

---

[2] Ibid., p. 245, 1899.

I commence with 1 per cent. menthol in this emulsion, and as quickly as the toleration of the patient permits I increase it to 10 per cent., and it has been in the rarer cases only that I have used 15 per cent. menthol. This is a drug that causes a burning pain, especially if applied as it has to be done, directly on the ulcerations. But as I should not like to miss its good effect, as above stated, I frequently induce preliminary anesthesia with the suprarenal gland. But many patients tolerate menthol without any pain whatever.

I wish to cite a few examples of cases treated in this manner.

C. B., 48 years of age, a cigar-maker, had been forty years in the United States. His mother died of dropsy, his father of old age, and one brother of tuberculosis. He has three children; one child died of pneumonia. He was a moderate drinker, but heavy smoker—20 to 30 cigars daily. Six years ago he had some diseases of the lungs, which kept him in bed five weeks.

Oct. 17, 1899, when seen, he was below the average height, and somewhat poorly nourished. Percussion was dull in the upper left portion anteriorly and posteriorly, with tenderness on percussion in many places, especially on the left shoulder. Over both lungs were numerous small moist râles, especially over the left apex; over the right apex expiration was roughened and prolonged. The spleen was enlarged and palpable, and there were tubercle bacilli in the sputum. The larynx showed interarytenoid infiltration with papillomatous excrescences, slight ulceration on the right side of the epiglottis. I injected menthol-orthoform emulsion—menthol 10 per cent.; no cocain.

By March 22, 1900, the ulcerations on the epiglottis were healed, and the interarytenoid infiltration had disappeared. The epiglottis was now marked horse-shoe shape, and much thickened. There was no pain till the day before. A broad, somewhat deep ulceration on the right aryepiglottic ligament was to be seen. For experiment, no application was made.

On March 26, pain in swallowing was severe, and he could eat but one meal daily. The ulcer was covered with a thick tenacious phlegm and debris. Cleansing of the ulcer and application of menthol-orthoform emulsion was tried, and repeated March 29, with such success that on April 2 the patient felt much easier again and could eat, but had some pain. The ulceration looked clear, and was only superficial.

On April 16, there was renewed attack of pain on the right side of the larynx. The right arytenoid was enlarged and edematous.

April 21, after a quantity of badly tasting pus had been expectorated, the patient again felt easier.

On May 14, subjectively, the patient remained the same during all the treatment; i. e., under regular treatment with orthoform-menthol emulsion he could swallow all the food he wanted, and his appetite being good he ate well. Only when taking thin fluids as water, tea, etc., he had to be careful, else he would get a paroxysm of coughing which would be followed by vomiting. Objectively his condition was worse. The epiglottis was very flat and very much thickened; the aryepiglottic ligaments—especially the right one—were infiltrated and the arytenoids enlarged. The ulcers would come and disappear again after treatment.

I selected this case first to show how a man with such advanced laryngeal tuberculosis can go around eating his meals regularly, joking and enjoying life. Of course, *quoad finem,* his prognosis is doubtful, especially as the condition of the lungs became worse. But if this man has to die we have at least saved him months and months of terrible, sometimes almost unbearable, pain. Besides, we have given him the possibility of being nourished well for the last six months, and if his power of resistance is strong enough he has another and greater chance of recovery. That such ulcerations do heal under the treatment mentioned, this case has shown repeatedly.

Before giving the history of the next case, let me quote from a former article of mine regarding surgical intervention in such cases. I remarked[3]: "I am able to report 29 cases the history of which I have found, although I know that more than double this number have been operated upon by me. I will, however. base my conclusions only upon these 29 accurately described cases. Of these 18 were not improved, in 7 a slow amelioration occurred which could be attributed to the operation, and in 4 an almost immediate improvement took place. Of the 18 unimproved cases, 13 were in an advanced stage of pulmonary phthisis, that is, with formation of cavities, etc., and 5 were in the earlier stages. None of these 18 patients experienced any relief after curettement; the majority, indeed, attributed the deterioration in their health to the operation, and in many cases I was of the same opinion. I was struck by the fact that a large number of infiltrations, with or without formation of ulcers, were in the interarytenoid space, forming the well-known polypoid excrescences on the posterior wall. In the 7 patients of the second class slow improvement occurred, and I have noted this in affections of almost all parts of the larynx. As this amelioration constantly followed on the surgical treatment, I consider myself justified in ascribing it to the latter. In considering the last 11 cases, one would be inclined to regard these surgical operations in the nature of a salvation, but unfortunately we must not lose sight of the first 18 cases, in which the results were not good. And if I were asked to give the indications for curettement I would not be able as yet to state them accurately, in spite of the fact that many laryngologists have studied the subject for over a decade. An important factor is that we are still unable to observe or appreciate the extension of the tuberculous process to the invisible portions of the larynx, or the contiguous parts, or otherwise to form an idea of its progress, which is governed by laws as yet unknown to us. As for me, I always regard such intervention as an experiment, and leave the decision to the patient. We learn, therefore, from the above statistics, that while we have been able to effect some excellent results, we have not been spared marked disappointment in a large number, and, indeed, in the majority of cases."

This was my standpoint somewhat over a year ago. I therefore resolved to try for one year without curettage. There were several cases in which, according to former views, curettement was indicated. Although I was tempted to do it repeatedly, I abstained, and after a year's trial without curettement, I believe my patients are just as well and perhaps better off than they would have been with the operation. Whether in the future I might not come across any cases in which it will be indicated, I can not say. My present view may be illustrated by the following case.

M. G., 49 years of age, a waiter, had been four years in the United States. His father died at 46, of some sudden throat illness, his mother at 58, of pneumonia; two sisters, two brothers and his wife and children are all well. He was well up to three years ago, when he had a chill, and on the following morning could not talk above a whisper. Last winter he began to cough and expectorate; no pain, but could not eat; had night sweats; has lost thirteen pounds in the last four months.

Sept. 20, 1899, there was extensive dulness over both upper lobes; exaggerated respiratory murmur; here and there moist râles. The left, anteriorly, in a limited area, showed slight bronchial breathing; there was whispered voice, the sounds not increased. The heart sounds were somewhat accelerated.

---

[3] Phila. Med. Jour., March 25, 1899.

The sputum contained tubercle bacilli. The patient had had repeated hemorrhages.

When my service commenced, on January 1, he had outspoken tuberculous laryngitis. especially infiltration of the left ventricular band. This infiltration was so marked that it covered the whole vocal cord. There were superficial ulcerations on the left aryepiglottic ligament, and the patient had considerable dysphagia. He received injections of orthoform-menthol emulsion, first only once a week, then twice weekly, and felt very much improved. During my temporary absence from the service he did not get the injection. and felt worse. His condition improved as soon as I resumed the treatment. No ulcerations were to be seen, but he felt better after the injection.

Now, after five months' treatment, the patient is in such a condition that he very rarely complains of pain. The infiltration is so much less that the vocal cord can be seen; there are no ulcerations, and the thickening of the left aryepiglottic ligament has disappeared. The patient would not think of submitting himself to operative interference, and I am of the same opinion. There is a great possibility that if we stopped with the orthoform-menthol emulsion his pain would return, also his irritating cough, and through that probably ulcerations and infiltrations (?) too. But as long as these injections can be administered so easily, why discontinue them? Why try anything else?

There is one point I can not emphasize enough, viz., to make these injections carefully. If one is in a hurry and injects the whole syringeful at once, in most cases a coughing spell will set in, and bring up all the emulsion. This will occur even when the preliminary anesthesia of the larynx with the suprarenal gland has been effective, as much of the emulsion goes down into the trachea. But if one is a little careful and injects the emulsion slowly, it will adhere to the surface, and the good results will surely appear.

Treatment with Oil.—There are some patients, however—and luckily they are the exceptions—who can not stand anything, be it cocain or anything else. They gag at the slightest provocation, or they vomit just as easily. These are patients who lack the smallest particle of energy, or who are exhausted from a very long illness, and near the end. For this class I have tried olive-oil.

Last year Paul Cohnheim, an assistant of Boas, of Berlin, reported the case of a man with ulcus ventriculi. This man, on his own account, had for weeks taken large doses of linseed-oil, and was thus cured. The oil worked like a grease—lubricant—by diminishing or abolishing the friction. We see this, as Cohnheim correctly says, in other parts of the body, too, as for example in the urethra and anus. Just as easily as large masses of feces pass the anus with comparative ease, even in the presence of rhagades or ulcers, so does food pass the oiled stenosed pylorus. Rosenheim applied this treatment in carcinoma of the esophagus, with surprisingly good results; also Boas and Akimo-Peretz saw good results. The latter gave 50 to 100 grams of an emulsion of oil of almonds daily before each meal.

I read all this only a short time ago, and it occurred to me that by lubricating the esophagus with any oil the food ought to pass more readily through that difficult place behind the infiltrations or ulcerations of the larynx, thus partly, at least, relieving the dysphagia. The first case treated in that way was that of M. Y., 34 years of age, a salesman. He was suffering from advanced tuberculosis of the lungs, and complained of great dysphagia and ulcers of the tongue. He was so weak that he could hardly sit up. An examination of the larynx was impossible, as he had too much pain in holding out his tongue. Insufflations with the suprarenal gland, or injections of the menthol-orthoform emulsion, or even cocain, were useless, as he vomited up everything. I therefore tried to improve his lingual ulcerations first. These were situated on and around the tip of the tongue. They spread especially on both sides, and under the tongue at least an inch in each direction. There was no diabetes nor any specific infection. In this case even the concentrated lactic acid had been used before he entered the home, with no good whatever. The application of the menthol-orthoform emulsion had the same negative result, and I am almost inclined to believe that orthoform has very little effect on the tongue, but as yet I can not judge sufficiently in that respect, as these cases are rare. At any rate, he did not improve, and as an experiment I gave him a glass of olive-oil one-half hour before his breakfast. After four days he said he could swallow a little easier. I now had 10 per cent. nitrate of silver applied to his tongue, and injected, into the larynx, a few drops of the menthol-orthoform emulsion, which he retained. The olive-oil was continued, and three days later he again felt better and I was able to examine his larynx. There were deep ulcerations on the epiglottis, and both aryepiglottic folds. The vocal cords were irregular and ulcerated. His tongue improving but slowly, I again tried lactic acid for it, but if anything it made it worse.

These cases of lingual tuberculosis are not frequent, and I just recall one case by C. E. Bean, of St. Paul.[4] He says: "Lactic acid has been very much vaunted, and one or two cases are reported as having been cured by means of this remedy, well rubbed into the ulceration; but the numerous failures to even afford temporary relief seem to demonstrate the fact that it is no more to be depended upon when the disease is situated in the tongue than when it has been developed in the larynx; and the result of treatment in that location has been disappointing." My experience is about the same. I can not report much more about the patient, except that within a few days he could swallow a little easier, and that he left for Europe.

The next case I treated with olive-oil was a private patient: N. O., 48 years of age, a business man. Eighteen years before he had acquired syphilis, and for four years had had tuberculosis. He complained only of great dysphagia, and the conditions were about the same as in the previous case. He rejected everything, and an examination in his bed was impossible. I ordered one glass of olive-oil every morning, which he took with great reluctance. After five days the house physician reported to me that there was some improvement in swallowing. I then saw him three days later, and after taking the olive-oil with great disgust he felt much better, as he had been able to take quite a little nourishment. As he had now decided to leave for the country I did not make any further trial with orthoform, etc., but advised him to continue for some time with the oil. At this last visit I saw in the larynx all the symptoms of advanced tuberculosis. A few weeks later I heard that his dysphagia was improving steadily. In the two other cases treated with olive-oil, I did not see any improvement whatever, and I shall not report them in detail. However. I consider it just, in suitable cases, to give this a further trial, and shall do so in the future.

Phototherapy.—The last of our resources in treating laryngeal tuberculosis is phototherapy, or treatment with the electric or sunlight. I have had some results with that treatment, but I have not reached any final conclusions in regard to it. However, I shall publish all my experience in phototherapy in the near future.

---

[4] Bean, C. E.: Report of Two Cases of Buccal Tuberculosis, N. Y. Med. Jour., Sept. 14, 1889.

Heroin for the Cough.—And now one word about the bronchial cough in these cases. Among the most distressing symptoms of laryngeal tuberculosis is the concomitant bronchial cough, which is often of a most harassing character, and contributes materially to the patient's exhaustion by preventing rest at night. For its relief we were formerly forced to rely on morphin and codein, although both these drugs left much to be desired. Aside from its well-known after-effects, morphin is particularly objectionable because of its tendency in many instances to disturb the digestive organs, and thus impair the patient's appetite. Codein, while in general preferable to morphin, has the disadvantage of being uncertain and unreliable in action. The introduction of heroin has been a decided advance in the treatment of cough in phthisical cases. In an article on the "Treatment of Dysphagia and Cough, Especially in Tuberculosis,"[5] I have reported my preliminary results with this new drug, which were most favorable. Since then its continued use has given very satisfactory results. The irritable cough in tuberculous patients frequently yields to the administration of heroin, and this occurs in cases in which both morphin and codein have proved completely inefficient. The action of heroin in modifying the respirations by diminishing their frequency and increasing their force, renders the breathing much easier. Aside from some lassitude and slight constipation, I have never observed the least after-effects from heroin, and as my experience relates now to several hundred cases in dispensary and private practice, I feel convinced that the drug is perfectly safe when used with ordinary precautions. In several instances, however, the constipation was sufficiently marked to call for the administration of laxatives, such as extract of cascara sagrada and aloin. My observations in this respect are in accord with those of Einhorn, Manges, and others, who have reported their results. Although we can not be sufficiently conservative in admitting to our confidence any new remedy which claims our attention, my experience with heroin has now been so extensive that I have no hesitation in assigning to it a prominent place in the list of medicaments for the relief of cough.

In summing up my experience with tuberculous laryngitis, I should like to emphasize the fact that there is a pathologic condition which might justly be called pretuberculous laryngitis. This ought to be treated with great care in every consumptive patient. Regarding the treatment of laryngeal tuberculosis we are nowadays fortunate enough to give great relief to by far the majority of these patients. Of these remedies which are so potent, I should like to mention: 1. The saccharated suprarenal gland for the induction of preliminary local anesthesia. 2. The menthol-orthoform emulsion for the production of a longer local anesthesia, and for its curative effects. 3. Olive, almond or sesame oil for the relief of the dysphagia. 4. Phototherapy. 5. Heroin for the relief of bronchial cough. Lactic acid ought to be dispensed with as antiquated and barbarous torture to the patients. Finally, I would like to say that here is a large field for further fruitful investigations in which every one ought to be interested; and the more we work in this field the more relief we shall give to our patients and the more cures we will effect.

DISCUSSION.

Dr. Emil Mayer, New York City—I would like to endorse the use of orthoform for this particular condition, and would call attention to the preparation with the white of the egg, for which I believe Dr. Freudenthal is responsible; that makes a very stable preparation and one that is valuable. I have found orthoform mixes very well with some of the liquid vaselin preparations, such as benzonol, and I have used that sometimes when the emulsion was not to be obtained. It may be said also that orthoform is not only of use for the painful deglutition that is associated with the tubercular trouble, but also in those conditions following operations. Nothing will give your patient so much comfort after a tonsillotomy as this emulsion.

Dr. Holbrook Curtis, New York City—One thing brought out was the use of the suprarenal extract. I reported, a few months ago, my first case, and I have now three using the extract for painful deglutition, and with most remarkable results. It has at the same time a most excellent effect on the edema. I have also used the suprarenal extract in quinsy and edema of the glottis with remarkable effect. I think it will prove of great value.

Dr. Richards—I would like to ask Dr. Freudenthal whether this solution can be sprayed through an atomizer.

Dr. Freudenthal—Not this solution; I use it with an ordinary laryngeal syringe.

Dr. W. Freudenthal—I am glad Dr. Mayer had the same experience as I did, and I shall try this solution in benzonol, which I think will be very good. I have not used this emulsion for tuberculous cases alone, but I have used it in syphilitic cases as well. In a case that came to me recently I injected this solution for severe pain, and the patient experienced almost immediate relief. The effect on edema is very good, which is due largely to its action as an astringent.

TREATMENT OF ATROPHIC RHINITIS BY ELECTROLYSIS.

AND SOME EXPERIMENTS TO DETERMINE THE EFFICIENCY OF NEEDLES OF DIFFERENT METALS.*

CAROLUS M. COBB, M.D.
BOSTON, MASS.

Atrophic rhinitis has been the bane of the rhinologist since the diseases of the nasal mucous membrane began to receive special attention. It is not at all surprising that the disease remained incurable during the time in which the diseases of the upper air-tract were treated by the ophthalmologist or otologist as a side issue to what he considered of more importance. Not only this, but most other diseases of the nasal cavities were considered incurable, not alone by the laity, but by the profession as well. This is hardly to be wondered at when we remember that the treatment of the different diseases of nasal cavities was much the same and consisted in the use of a spray and the application of a solution of nitrate of silver to the surface of the nasal mucous membrane or to such part of it as could be easily reached. The patients were given a spray to use at home, and I think that they accomplished as much by its use as was accomplished by the physician himself. These sprays were usually composed of varying combinations of alkalies, and each specialist had a formula of his own which he was only too apt to think was a specific. In the use of watery sprays the fact that the nose was made for the passage of air and not for water, seems to have been overlooked. That these sprays gave temporary relief, but did not cure, was at last recognized by all, and while it may be necessary for the physician to occasionally use a spray for cleansing purposes, I am inclined to think it is well for the patient to cleanse his own nose as a rule.

The medical sprayer, if you will allow the expression, did not cease to exist when he found that sprays did not cure nasal disease, but the argument was changed and he frankly admitted that the so-called catarrhal diseases were incurable in this climate—it made no particular difference where he might be, one place was too windy, another too dusty, another too cold, in another the climate was too variable, etc., ad nauseam—but if the patient will use this spray, the disease will be prevented from growing worse. This advice was given to all patients, but more especially to those who suffered from one of the most horrible of the diseases of the nasal cavities, horrible not from disfigurement or from danger to life, but from the persistent and almost unbearable odor which accompanies it. In this disease it would seem that a spray might be of some use, and it undoubtedly is of some slight benefit, but there is usually not enough of it in volume or force to dislodge the crusts, and if the patients rely on the spray for treatment they are condemned to live with this disgusting odor always with them, an object of aversion to themselves and avoided by their friends. Fortunately they early lose the sense of smell and in this way are relieved of a part of their burden.

---

[5] Phila. Med. Jour., March 25, 1899.

* Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

To cure this disease confers as great an obligation on these patients and their friends as the cure of any other loathsome disease. With the zeal born of specialism, earnest, intelligent men have set themselves the task to accomplish this object, and while much yet remains to do, we have already succeeded to a great extent in curing the disease. As is often the case, our treatment has outrun our knowledge of etiology, and while we are already able to cure a large proportion of the patients, we do not know as yet what part the bacteria play in the production of the disease, neither do we know how much the disease may depend upon or be influenced by the general systemic condition or by the presence of a nasal empyema, or what part the cephalic index may play as a predisposing cause. It has not yet been definitely settled whether the bacteria which are found in such numbers in the nasal cavities in cases of atrophic rhinitis are of primary or of secondary importance, and as I have nothing new to offer, I will not take your time with a review of the opinions of others on the subject. I do wish to call your attention to the importance of a close differential diagnosis between true atrophic rhinitis and disease of the accessory sinuses. That many of the cases which are diagnosed as atrophic rhinitis have their origin in a nasal empyema there is not the slightest doubt. I have seen so many cases with all the symptoms of a typical atrophic rhinitis and have found after the crust formation was stopped that there was a discharge from a nasal empyema, that I feel that the recognition of this condition can not be insisted upon too strongly. Whether the nasal empyema—when it exists—is of primary or of secondary etiological importance is a question to be decided by the physician in each case, but if we expect to be successful in treating these cases, the nasal empyema must receive attention. The diagnosis of this complicating disease is easily made. If after the nasal cavity is thoroughly cleansed we find pus appearing within a short time in one or both the pathways of the drainage from the accessory sinuses, we may feel reasonably sure that we have to deal with a collection of fluid in one or more of the sinuses. The enlarged middle turbinate which is so often found in cases of atrophic rhinitis may be the cause of a nasal empyema by interfering with the drainage from the accessory sinuses, or the cell which is contained in this enlargement may be the site of the empyema. If we are satisfied that we have to deal with a nasal empyema as a complication of the atrophic condition, we should not hesitate to remove enough of the turbinate to improve the drainage. I have removed the anterior wall of the enlarged middle turbinate, with the most gratifying results, in cases where I had reason to believe that the empyema was the cause of the crust formation. It is always well to examine very thoroughly for a possible sinus involvement those cases which follow scarlet fever, measles, typhoid fever, diphtheria and erysipelas. If a nasal empyema is found to exist it is unnecessary to add that it should be treated by thorough drainage. What proportion of the cases of atrophic rhinitis depend upon sinus disease is very hard to determine; from my own experience I should think fully 50 per cent. have this origin or are seriously influenced by this complication.

After this brief review of the most important complication of the disease, we will next consider its treatment by electrolysis. In 1895, at the meeting of the Belgian Laryngologists and Otologists, held in Brussels, Cheval announced that he had been able to cure 91 per cent. of his cases of ozena by interstitial electrolysis. This statement was received with more or less incredulity by the other laryngologists, and the method was tested very thoroughly by Bayer, of Brussels, and by many others during the next year. Bayer, who was at first skeptical, after a year's experience reported favorably, as did many others. Among the enthusiastic advocates of the method are Brindel, of Bordeaux; Rethi, of Vienna, and McBride, of Edinburgh. All observers unite in the report that there is an immediate and decided lessening of the odor and a marked decrease in the amount of crusts and that they are easily removed from the nose. The improvement often occurs after the first treatment and it rarely requires more than five or six applications to accomplish all that can be hoped for. Cheval reports that 70 patients were cured in a single sitting, 12 required several, and 3 were still under treatment. One case was improved, but not cured after six sittings. One of the most striking results of the treatment is the disappearance of all odor. This often occurs on the day of the first treatment, and it may not return for months, even though the crust formation does not entirely cease. The important question then is, For how long a time does this improvement continue? This will, of course, vary in individual cases, and may be from a few months to a year or more. McBride exhibited two cases before the British Medical Association, in 1898, in whom the improvement had lasted for a year without any return of the odor and with but slight tendency to crust formation. Brindel, while noting improvement in all, admits that it is not permanent. In the ten cases which he reports, at the time of writing there was no return of the odor or crusts, and they had been under treatment as follows: 1, eleven months previously; 3, ten months; 1, nine months; 1, eight months; 2, seven months; 1, five months; 1, three months. Of these only two could be said to be cured, that is, in which the atrophy had entirely disappeared. Hajek and Chiari both have protested against considering these cases as cured when the odor and crusts have only been relieved, but no anatomical changes have taken place. Mendelsohn also cautions against placing too much reliance on the permanence of the cure.

If we seek for an explanation of the effect of the galvanic current upon the tissues in cases of atrophic rhinitis, we find various opinions expressed by different writers. Bayer attributes it to the effect upon the nervous system, Gautier and Javier to the deposition of a copper salt in the tissues, Delavan to the mechanical stimulation of the tissues. If we investigate the action of the galvanic current upon living tissue we shall be able perhaps to explain the effect which it has in these cases. In doing this we must of necessity go over much ground that is perfectly familiar to you all. It may be well in the beginning to make this statement: that the passage of the electrical current, as we know it, is always destructive to cell life, that it is always and everywhere a life-destroyer and not a life-giver. If the destruction is not carried too far it may act as a stimulant and it may also have a remedial action by liberating certain elements from the tissues through which it passes or by depositing remedies in them. It is not material whether we consider the change in the cell by which this destruction is accomplished as chemical or mechanical. The galvanic current outside of the battery passes from the positive to the negative pole and when passing through living tissue carries along with it a certain amount of the basic elements of the cells, thus destroying their chemical structure. The removal of the base from the salt liberates those elements which are known as the acid-forming, and these being liberated by the current appear at the positive pole. Oxygen and chlorin are the elements that appear at the positive pole, with perhaps others in infinitesimal quantities, and they unite with the metal of the electrode and form a salt which may in turn be decomposed and the metal carried along with the current. It is evident that many things may have an influence over this electrolytic action. The first to be considered is the resistance of the tissues, which, of course, varies for the different structures through which the current passes, and while we are not able to estimate this for different tissues and perhaps different individuals, we do know that all of the current does not follow the path of least resistance; for example, if we have two substances, one of 1 ohm resistance and the other of 1000 ohms, the current will pass through the higher resistance in inverse proportion to the lesser. We have next to take account of the diffusion of the current. This is probably about equal to the diffusion which takes place when a current passes through the earth; at least we have no better way of estimating it. An electrical current passing through the earth between points one mile apart is diffused about 1100 feet each side from the center, or a lateral diffusion of rather more than one-third of the linear distance, and forms an almost perfect ellipse. There is a large conducting area for the current as soon as it leaves the needle, and, further, the current does not all pass from the needle on the side toward the other pole, and in the use of electricity in the treatment of disease it is rarely possible to place the two poles in the most favorable position to obtain least diffusion. It would seem to follow from this that the best results would be obtained when it was possible to concentrate the current, and this has been the result of experience in other branches of medicine.

After this brief allusion to some of the factors which influence electrolytic action in the tissues of the human body, we will now consider the direct effect when a positive electrode of copper or other metal is used. If a copper needle is used for the positive pole, we should expect to have formed an oxygen and chlorin compound of copper, and this was the salt that Cheval and Bayer found, by chemical analysis, deposited on the positive pole. If another metal is used—with the exception of platinum, which is not affected by the gases liberated by the electrical current—we should get a salt with the metal used as a base. It has been claimed that the oxychlorid of copper is soluble in the lymph plasma, and some writers think that the beneficial results are obtained by the diffusion of this solution of the oxychlorid of copper through the tissues. We will speak of the solubility of this salt in connection with the inquiry into the amount of copper salts which may be obtained by electrolysis. It is interesting to inquire how much of this salt is deposited in the tissues during an ordinary treatment by electricity. According to Park Benjamin, one ampere flowing for one hour would liberate 1 1/10 grams of an —ic salt, or 2 3/10 grams of an —ous salt. It is quite probable that the salt formed in the tissues is a mixture of the two, and we will call it, speaking roughly, 20 grains of the combined salt. Twenty milliamperes, which is a very liberal dose of electricity, would therefore liberate one-fiftieth of 20 grains in one hour, and in ten minutes, the usual length of the sitting, one three-hundredth part of 20 grains or one-fifteenth part of 1 grain. To deposit 1 grain of a mixed salt of copper in the tissues would require one hundred and fifty minutes, or two and one-half hours. These figures are, of course, not absolutely accurate, but are approximately so. In this connection it is well to call attention to the question of the solubility of the oxychlorid of copper which is found deposited upon the positive pole. In Roscoe's chemistry several oxychlorids are given. He notes the most common one, which is known in commerce as Brunswick green. The oxychlorids are evidently varying mixtures of the oxid and chlorid of copper, which would, in the presence of a saline solution like the lymph-plasma, break up and the chlorid salt would be dissolved, the oxid remaining in an undissolved condition. The fact that Cheval was able to remove enough of the oxychlorid of copper from the copper needle for chemical analysis would seem to indicate that the salt which is formed upon the surface of the copper needle is insoluble. It will be seen from the varying chemical and electrolytic conditions which may influence the deposition of a salt of copper that it is manifestly impossible to determine the amount which would be left in the tissues during an ordinary treatment by electrolysis, but we may be sure that under the most favorable conditions it would be no more than the amount which I have given, and it is probably less.

It does not seem as though the deposition of an infinitesimal amount of a mixed salt of copper in the tissues could produce the immediate and lasting results which follow the interstitial application of the galvanic current; and while it is not claimed that even the small amount of copper which it may be possible to deposit possesses no remedial properties, I have not been able to detect any difference in the results when either copper, silver, steel or platinum needles were used as the positive pole, or when both poles were of the same metal. I will not weary you by giving any detailed case histories, but will simply give the summary of the cases treated: Whole number of cases treated, 15; those in which the nasal empyema was of paramount importance, 8; number treated by copper and platinum, 2; by steel and platinum, 1; by silver and platinum, 2; by platinum and platinum, 2. I took the cases in rotation from my clinic and private practice, and I am fortunate in being able to report an equal number treated by the different electrodes, except the steel. I have not included those cases where the sinus disease predominated, because I not only used electricity, but improved the drainage as well, and in some of the cases repeatedly washed out the affected sinus. I do not feel that it would add to our knowledge of the value of electrolysis as a remedial agent in the treatment of atrophic rhinitis to include the good results obtained by measures directed to the relief of the nasal empyema. Of these seven cases of atrophic rhinitis, four were relieved of the odor and crust formation in one sitting, two in three sittings, and one in five. Two of them have remained free from odor and nearly free from crust formation for fourteen months, three for eleven months, one for eight months, and one had a return in a little over two months. The cases of nasal empyema were all very much benefited by the improvement in the drainage and the washing out of the cavities involved, but, as often occurs in the treatment of nasal empyema, the discharge was not entirely stopped in all of them. There is one point that should not be neglected, namely, that the improvement in the crust formation may improve the drainage from the accessory sinuses to such a degree that the nasal empyema which is an accompaniment, if it be not a cause of the crusts, is made permanently better.

I have gone very fully into the question of the deposition of copper in the tissues because I believe it is well to know, when it is possible to do so, to what to ascribe the results which we obtain by any method of treatment. It now remains for us briefly to consider the question of the mechanical stimulation of the tissues and the effect upon the nervous system of interstitial electrolysis. The mechanical effect of the passage of the galvanic current through the tissues of the body may, for all practical purposes, be considered as nothing. Even if the current produced decided mechanical effect, this would not explain the results obtained by this method of treatment, for it is a well-known fact that other forms of mechanical stimulation have to be repeated at short intervals and for a considerable length of time; for instance, those who use vibratory massage in the treatment of atrophic rhinitis recommend that it be used every other day for three months, and then at longer intervals for several months more. There is every reason to believe that the galvanic current is an irritant to the nerves when it is brought in contact with them, but this irritation lasts practically only so long as the contact exists and it hardly seems possible that the application of the galvanic current would produce such lasting results. I am very well aware that the use of electricity is vaguely supposed to be beneficial in the treatment of nervous diseases, but I think that I am stating what is the general opinion of the leading neurologists when I say that, with one exception, the use of electricity is confined to diagnosis and not to treatment. The exception is the use of the faradic current in the treatment of some forms of muscular atrophy and the unanimity of opinion in regard to its use shows very conclusively that the faradic current is not of benefit in other conditions. The action of the faradic current has been defined as a mechanical massage, and this definition explains the results obtained by its use. If the action of the galvanic current in cases of atrophic rhinitis can not be attributed to any of the theories given, to what then is it due? If we go back to the explanation of the effect produced by the passage of the galvanic current we shall find that it breaks the chemical combination of the cell by its power to attract the basic elements and that they appear at the negative pole and that it repels the elements that are known as the acid-formers and that they appear at the positive pole. The effect of a current which produces therapeutic results must be the same, only to a less degree, as that which is produced by the larger volume of current. If the destruction of the tissues of the body by the galvanic current is mechanical, then the therapeutic effect is the result of mechanical action, but I think no one claims that this is so. As I said earlier in this paper, the passage of the electrical current always produces the same result, the destruction of the cells, and this is only modified in degree, but not in character, by the amount of the current which passes, and by the force which drives it through the tissues. Between the large volume of current which produces extensive destruction of tissue and the very weakest, which is practically inert, lies the therapeutic use of the galvanic current. The action of the current is probably mostly confined to the soft parts, as the periosteum is a poor conductor of electricity. In the chemical destruction of the cells of the soft parts, the weakest cells are destroyed first, and this occurs in two ways: 1, by the direct action of the current, and 2, by the action of the acid-forming elements which are liberated around the positive pole. That the bacteria are also destroyed by the same action, the examinations of Bayer would seem to indicate, as he found that the number of colonies was very much reduced after treatment by electrolysis. The source of the oxygen and chlorin which are liberated around the positive pole is very largely the lymph-plasm; this is composed of over 90 per cent. of water, holding in solution albumin, fibrin, fatty matter, extractive matter and salts of sodium, potassium, calcium and magnesia. Of these various salts, sodium chlorid occurs in the greatest quantity, being 65.2 per cent. of the inorganic salts. From this brief review of the chemical composition of the fluid upon which the galvanic current must have the greatest effect, it will be readily seen from what source the oxygen and chlorin are obtained which are liberated around the positive pole. The water and the chlorid of sodium are broken up into their constituent elements by the action of the electrical current. If an electrode of platinum is used on the positive pole the oxygen and chlorin thus liberated are free to unite with the tissues; that they remain free in the tissues or that they escape does not seem probable when we remember the avidity with which these elements unite with others to form new combinations. While these substances are formed in minute quantities, still the effect may be, and undoubtedly is, considerable. The destruction of the cells and the liberation of oxygen and chlorin around the positive pole, which unite with the other elements to form new combinations that may be, temporarily at least, acid in reaction, in my opinion, is the explanation of the results obtained in the treatment of atrophic rhinitis by interstitial electrolysis. The effect is local, and in some cases immediate, the odor and crust formation often disappearing on the day of the first treatment; and coincident with this result is the change in the character of the secretion which, from being ropy and sticky, becomes liquefied and easily removed. This would tend to prove that there was a change in the chemical reaction of the tissues, or at least of the secretion, produced almost at once.

Many of the writers advise placing the needle of the negative pole beneath the mucous membrane of the septum; I do not consider this a safe procedure, for the reason that the sodium and potassium which are liberated around the negative pole are active escharotics and are liable to cause the destruction of considerable tissue, and may even cause perforation of the septum. There can be no doubt that we have in interstitial electrolysis a remedial agent of undoubted efficacy and that copper salt in the tissues, Delavan to the mechanical stimulation of the tissues. If we investigate the action of the galvanic current upon living tissue we shall be able perhaps to explain the effect which it has in these cases. In doing this we must of necessity go over much ground that is perfectly familiar to you all. It may be well in the beginning to make this statement: that the passage of the electrical current, as we know it, is always destructive to cell life, that it is always and everywhere a life-destroyer and not a life-giver. If the destruction is not carried too far it may act as a stimulant and it may also have a remedial action by liberating certain elements from the tissues through which it passes or by depositing remedies in them. It is not material whether we consider the change in the cell by which this destruction is accomplished as chemical or mechanical. The galvanic current outside of the battery passes from the positive to the negative pole and when passing through living tissue carries along with it a certain amount of the basic elements of the cells, thus destroying their chemical structure. The removal of the base from the salt liberates those elements which are known as the acid-forming, and these being liberated by the current appear at the positive pole. Oxygen and chlorin are the elements that appear at the positive pole, with perhaps others in infinitesimal quantities, and they unite with the metal of the electrode and form a salt which may in turn be decomposed and the metal carried along with the current. It is evident that many things may have an influence over this electrolytic action. The first to be considered is the resistance of the tissues, which, of course, varies for the different structures through which the current passes, and while we are not able to estimate this for different tissues and perhaps different individuals, we do know that all of the current does not follow the path of least resistance; for example, if we have two substances, one of 1 ohm resistance and the other of 1000 ohms, the current will pass through the higher resistance in inverse proportion to the lesser. We have next to take account of the diffusion of the current. This is probably about equal to the diffusion which takes place when a current passes through the earth; at least we have no better way of estimating it. An electrical current passing through the earth between points one mile apart is diffused about 1100 feet each side from the center, or a lateral diffusion of rather more than one-third of the linear distance, and forms an almost perfect ellipse. There is a large conducting area for the current as soon as it leaves the needle, and, further, the current does not all pass from the needle on the side toward the other pole, and in the use of electricity in the treatment of disease it is rarely possible to place the two poles in the most favorable position to obtain least diffusion. It would seem to follow from this that the best results would be obtained when it was possible to concentrate the current, and this has been the result of experience in other branches of medicine.

After this brief allusion to some of the factors which influence electrolytic action in the tissues of the human body, we will now consider the direct effect when a positive electrode of copper or other metal is used. If a copper needle is used for the positive pole, we should expect to have formed an oxygen and chlorin compound of copper, and this was the salt that Cheval and Bayer found, by chemical analysis, deposited on the positive pole. If another metal is used—with the exception of platinum, which is not affected by the gases liberated by the electrical current—we should get a salt with the metal used as a base. It has been claimed that the oxychlorid of copper is soluble in the lymph plasma, and some writers think that the beneficial results are obtained by the diffusion of this solution of the oxychlorid of copper through the tissues. We will speak of the solubility of this salt in connection with the inquiry into the amount of copper salts which may be obtained by electrolysis. It is interesting to inquire how much of this salt is deposited in the tissues during an ordinary treatment by electricity. According to Park Benjamin, one ampere flowing for one hour would liberate 1 1/10 grams of an —ic salt, or 2 3/10 grams of an —ous salt. It is quite probable that the salt formed in the tissues is a mixture of the two, and we will call it, speaking roughly, 20 grains of the combined salt. Twenty milliamperes, which is a very liberal dose of electricity, would therefore liberate one-fiftieth of 20 grains in one hour, and in ten minutes, the usual length of the sitting, one three-hundredth part of 20 grains or one-fifteenth part of 1 grain. To deposit 1 grain of a mixed salt of copper in the tissues would require one hundred and fifty minutes, or two and one-half hours. These figures are, of course, not absolutely accurate, but are approximately so. In this connection it is well to call attention to the question of the solubility of the oxychlorid of copper which is found deposited upon the positive pole. In Roscoe's chemistry several oxychlorids are given. He notes the most common one, which is known in commerce as Brunswick green. The oxychlorids are evidently varying mixtures of the oxid and chlorid of copper, which would, in the presence of a saline solution like the lymph-plasma, break up and the chlorid salt would be dissolved, the oxid remaining in an undissolved condition. It will be seen from the varying chemical and electrolytic conditions which may influence the deposition of a salt of copper that it is manifestly impossible to determine the amount which would be left in the tissues during an ordinary treatment by electrolysis, but we may be sure that under the most favorable conditions it would be no more than the amount which I have given, and it is probably less.

It does not seem as though the deposition of an infinitesimal amount of a mixed salt of copper in the tissues could produce the immediate and lasting results which follow the interstitial application of the galvanic current; and while it is not claimed that even the small amount of copper which it may be possible to deposit possesses no remedial properties, I have not been able to detect any difference in the results when either copper, silver, steel or platinum needles were used as the positive pole, or when both poles were of the same metal. I will not weary you by giving any detailed case histories, but will simply give the summary of the cases treated: Whole number of cases treated, 15; those in which the nasal empyema was of paramount importance, 8; number treated by copper and platinum, 2; by steel and platinum, 1; by silver and platinum, 2; by platinum and platinum, 2. I took the cases in rotation from my clinic and private practice, and I am fortunate in being able to report an equal number treated by the different electrodes, except the steel. I have not included those cases where the sinus disease predominated, because I not only used electricity, but improved the drainage as well, and in some of the cases repeatedly washed out the affected sinus. I do not feel that it would add to our knowledge of the value of electrolysis as a remedial agent in the treatment of atrophic rhinitis to include the good results obtained by measures directed to the relief of the nasal empyema. Of these seven cases of atrophic rhinitis, four were relieved of the odor and crust formation in one sitting, two in three sittings, and one in five. Two of them have remained free from odor and nearly free from crust formation for fourteen months, three for eleven months, one for eight months, and one had a return in a little over two months. The cases of nasal empyema were all very much benefited by the improvement in the drainage and the washing out of the cavities involved, but, as often occurs in the treatment of nasal empyema, the discharge was not entirely stopped in all of them. There is one point that should not be neglected, namely, that the improvement in the crust formation may improve the drainage from the accessory sinuses to such a degree that the nasal empyema which is an accompaniment, if it be not a cause of the crusts, is made permanently better.

I have gone very fully into the question of the deposition of copper in the tissues because I believe it is well to know, when it is possible to do so, to what to ascribe the results which we obtain by any method of treatment. It now remains for us briefly to consider the question of the mechanical stimulation of the tissues and the effect upon the nervous system of interstitial electrolysis. The mechanical effect of the passage of the galvanic current through the tissues of the body may, for all practical purposes, be considered as nothing. Even if the current produced decided mechanical effect, this would not explain the results obtained by this method of treatment, for it is a well-known fact that other forms of mechanical stimulation have to be repeated at short intervals and for a considerable length of time; for instance, those who use vibratory massage in the treatment of atrophic rhinitis recommend that it be used every other day for three months, and then at longer intervals for several months more. There is every reason to believe that the galvanic current is an irritant to the nerves when it is brought in contact with them, but this irritation lasts practically only so long as the contact exists and it hardly seems possible that the application of the galvanic current would produce such lasting results. I am very well aware that the use of electricity is vaguely supposed to be beneficial in the treatment of nervous diseases, but I think that I am stating what is the general opinion of the leading neurologists when I say that, with one exception, the use of electricity is confined to diagnosis and not to treatment. The exception is the use of the faradic current in the treatment of some forms of muscular atrophy and the unanimity of opinion in regard to its use shows very conclusively that the faradic current is not of benefit in other conditions. The action of the faradic current has been defined as a mechanical massage, and this definition explains the results obtained by its use. If the action of the galvanic current in cases of atrophic rhinitis can not be attributed to any of the theories given, to what then is it due? If we go back to the explanation of the effect produced by the passage of the galvanic current we shall find that it breaks the chemical combination of the cell by its power to attract the basic elements and that they appear at the negative pole and that it repels the elements that are known as the acid-formers and that they appear at the positive pole. The effect of a current which produces therapeutic results must be the same, only to a less degree, as that which is produced by the larger volume of current. If the destruction of the tissues of the body by the galvanic current is mechanical, then the therapeutic effect is the result of mechanical action; but I think no one claims that this is so. As I said earlier in this paper, the passage of the electrical current always produces the same result, the destruction of the cells, and this is only modified in degree, but not in character, by the amount of the current which passes, and by the force which drives it through the tissues. Between the large volume of current which produces extensive destruction of tissue and the very weakest, which is practically inert, lies the therapeutic use of the galvanic current. The action of the current is probably mostly confined to the soft parts, as the periosteum is a poor conductor of electricity. In the chemical destruction of the cells of the soft parts, the weakest cells are destroyed first, and this occurs in two ways: 1, by the direct action of the current, and 2, by the action of the acid-forming elements which are liberated around the positive pole. That the bacteria are also destroyed by the same action, the examinations of Bayer would seem to indicate, as he found that the number of colonies was very much reduced after treatment by electrolysis. The source of the oxygen and chlorin which are liberated around the positive pole is very largely the lymph-plasm; this is composed of over 90 per cent. of water, holding in solution albumin, fibrin, fatty matter, extractive matter and salts of sodium, potassium, calcium and magnesia. Of these various salts, sodium chlorid occurs in the greatest quantity, being 65.2 per cent. of the inorganic salts. From this brief review of the chemical composition of the fluid upon which the galvanic current must have the greatest effect, it will be readily seen from what source the oxygen and chlorin are obtained which are liberated around the positive pole. The water and the chlorid of sodium are broken up into their constituent elements by the action of the electrical current. If an electrode of platinum is used on the positive pole the oxygen and chlorin thus liberated are free to unite with the tissues; that they remain free in the tissues or that they escape does not seem probable when we remember the avidity with which these elements unite with others to form new combinations. While these substances are formed in minute quantities, still the effect may be, and undoubtedly is, considerable. The destruction of the cells and the liberation of oxygen and chlorin around the positive pole, which unite with the other elements to form new combinations that may be, temporarily at least, acid in reaction, in my opinion, is the explanation of the results obtained in the treatment of atrophic rhinitis by interstitial electrolysis. The effect is local, and in some cases immediate, the odor and crust formation often disappearing on the day of the first treatment; and coincident with this result is the change in the character of the secretion which, from being ropy and sticky, becomes liquefied and easily removed. This would tend to prove that there was a change in the chemical reaction of the tissues, or at least of the secretion, produced almost at once.

Many of the writers advise placing the needle of the negative pole beneath the mucous membrane of the septum; I do not consider this a safe procedure, for the reason that the sodium and potassium which are liberated around the negative pole are active escharotics and are liable to cause the destruction of considerable tissue, and may even cause perforation of the septum. There can be no doubt that we have in interstitial electrolysis a remedial agent of undoubted efficacy and that we may confidently expect from its use, in a large percentage of the cases at least, that the odor will cease, that the crust formation will be lessened, that the nasal mucous membrane will become moist and healthy in appearance, and that the secretion will become liquefied and lose its ropy, sticky character, and that these results will last for several months. It is needless to add that this is a more favorable showing than can be secured by any other known method of treatment. Electricity will not stop the discharge when this depends upon a nasal empyema, although it may have a beneficial effect upon the crust formation even in these cases; neither will it stop the odor when that depends upon the same cause. The conclusions to which I wish to draw your attention are:

1. Electrolysis has a curative action in atrophic rhinitis in so far as it stops the tendency to crust formation and the odor, in typical cases.
2. It does not stop the discharge or the odor if these are caused by nasal empyema.
3. That better results are obtained if the needles are placed comparatively near together.
4. That it makes no difference in the result what metal is used for needles, and it therefore follows that the diffusion of the copper salt is evidently not the curative agent.
5. That the improvement in the condition of the nasal mucous membrane is most noticeable in the area around the positive pole.
6. That this improvement is probably due to the liberation of oxygen and chlorin, and the chemical change resulting from the presence of free oxygen and chlorin in the tissues or the acid reaction produced thereby.
7. That the needle of the negative pole should not be placed beneath the membrane of the septum.

I wish in closing to acknowledge my indebtedness to Dr. C. L. Sopher, of Wakefield, Mass., for his valuable assistance in collecting electrical data for this paper.

419 Boylston Street.

DISCUSSION.

DR. J. F. CULP, Harrisburg, Pa.—I was very much interested listening to Dr. Cobb's paper this morning. There is one thing he did not mention, that is, the unpleasant effect following the application of the electric current in the treatment he mentioned. Such effects are sometimes even more than unpleasant. I have personally seen this method tried and violent headache follow its application. I have seen very decided earache, and I have heard of decided syncope following the application of the current. In regard to the statistics attending this method of treatment, some of them are fallacious, for I personally know of cases that have been reported as cured, and in which the physician has spoken in the highest term of the cure, that have relapsed in a very short time after the publication of the paper reporting them. Undoubtedly there is very much in the treatment, and I think I express the opinions of some of the other members of the ASSOCIATION when I say I would like very much to hear a little more of the detail of the application of this method of treatment.

DR. EDWARD PYNCHON, Chicago—A good idea is that of having the patient attend to the cleansing part himself. I have done this, and am not afraid of having the patient use the douche twice a day, at first, perhaps, with a solution of phenol, and afterward with bicarbonate of soda, a teaspoonful to a pint. I also insist on his sniffing, every hour, a small quantity of an alkaline solution, perhaps a one-half strength of the Dobell solution. In this way I have had no trouble in controlling the ozenous condition in atrophic rhinitis or in sinus disease. In connection with the atrophy, there is almost invariably present a hypertrophic condition of the middle turbinal upon the same side, and I have had very satisfactory results by early surgical treatment of such hypertrophied body. One thing which keeps up the condition of atrophy is the fact that there is an increased current of air in the lower part of the nose, as it can not circulate in the upper part of the nose owing to the occlusion thereof.

DR. C. M. COBB, Lynn, Mass.—In regard to the strength of current and the details and unpleasant symptoms that may result, and last but not least the duration of the cure, no one claims that these cases are permanently cured. In many instances they will stay in a reasonably comfortable condition for months. If they have been using any wash or cleansing spray at all they are very likely to keep using it, and that will often deceive you as to how much you have done. I invariably tell them to do nothing with the nose, that they may blow the crusts out, but that they should not use any spray. The treatment simply prevents any secretion sticking to the mucous membrane. Whether there is just as much secretion, or whether there is more I can not say; but it does not stick and form crusts. I use a platinum needle, which is not easily affected and is easily kept clean, and does not form any oxid or other salts. One little point is that you must keep the needles apart in their course, for if you get a short circuit before the current gets into the tissues you will not get any effect. I use a rheostat like the one used by dentists. I never use an amperemeter because it is not possible for the instrument-makers to make an accurate milliamperemeter at the price they charge for them. They are approximately correct, that is, some of them are and some are not. But if you have a rheostat so you can control the current, and then turn the current on until the patient is sensible of it you will not be likely to use too much current and cause headache. Another thing, if you introduce the needles into the bone of the middle turbinated you are much more likely to give a shock to the patient. I think the nasal speculum of hard rubber is a great advantage. I have a patient under treatment, and when he asked why I did not use the battery on the other side I told him that my battery was out of order. He perhaps thinks that it is a long time being fixed, but the truth is, I wanted to see how he would do without the use of the battery. You know some believe that the treatment affects not only the side to which you apply the current, but also the other side and the pharynx as well. I do not think that this is true. In the case I have mentioned the man has one side comparatively comfortable, while the other side, to which the current was not applied, is about the same as it was before. Dr. Pynchon mentioned hypertrophy of the middle turbinated. In those cases I remove the anterior part of the middle turbinated, and it is wonderful how much of the atrophy supposed to exist in the lower turbinated disappears. The nose becomes moist and the patient is more comfortable. It is not necessary in these cases to remove the whole turbinated, but if you will cut a good sized section out of it you will improve the case in every way.

THE NATURE AND TREATMENT OF VERTIGO.*

J. LEONARD CORNING, A.M., M.D., LL.D.
NEW YORK CITY.

Among the various consequences of organic and functional disturbance of the nervous system with which we are called upon to deal, what is technically known as vertigo is surely one of the most common. Often insidious in its advent, obscure as to ultimate pathology, in its treatment baffling, it has come to be regarded as a most slippery adversary, a kind of ignis fatuus of the clinic, at the view of whose antics and illusive ways erudition and experience stand aghast.

Yet despite the unsatisfactory condition of present knowledge, there is no denying the eminent practical importance of the subject. Consider for a moment the amount of apprehension and annoyance caused by the symptom itself; then its frequency, as an accompaniment or sequence of the most disparate pathological conditions, and you will concede, I think, that a warrant is provided, sufficient to justify a careful sifting of available data, an analysis of which may incite, perhaps, to the formation of a more consistent concept of the phenomenon itself, and hence to more rational management.

Besides the more common forms of vertigo described in the books: that which accompanies disorders of the stomach; that due to lithemia—the most common of all, in my experience—that associated with disease of the inner ear—Ménière's disease—that found in chlorosis and other forms of debility, and notably in neurasthenia; that traceable to ocular difficulties; and that associated with epilepsy, toxic agencies externally or internally derived, etc., the more conventional varieties; there are many others, less commonly regarded, notably those associated with cerebral and cerebellar disease; compression of the medulla oblongata; multiple sclerosis; meningitis; spinal concussion and oculomotor paralyses.

---

* *Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.*

To enter into a discussion of these individual varieties would quite transcend the limits and objects of the present paper, involving as it would the citation of an enormous array of collateral symtomatology—the symptomatology of the various diseases of which vertigo is but a single, albeit an important, symptom.

I speak advisedly of vertigo as a symptom, for the very good reason that, as you all know, there is no single lesion which may be regarded as peculiarly that of the affection itself.

Disparate, however, as are the conditions which may give rise to vertigo, I am confident that their ultimate effect upon certain important cerebral faculties must be practically the same. And, if called upon to say in few words in just what—psychologically speaking—the essence of vertigo consists, to define as far as may be the condition of the mind during vertigo, I would state that general or special perception is more or less perverted, and consciousness diminished in scope and alertness, whereby the faculty of orientation possessed by the individual—that faculty by virtue of which he is able to keep accurately informed respecting his relations to his environment—is manifestly impaired.

This statement of the author is not, however, to be received as an attempt at infallible utterance touching a matter of conceded complication; but is rather to be regarded in the light of a thesis whose tenability he will endeavor to defend by such facts and arguments as he is able, at this time, to bring forward.

In the first place, then, it were well to remember that those ganglionic mechanisms of the brain most intimately associated with perception may suffer derangement in two ways:

1. They may undergo more or less direct derangement from adverse potentialities acting within the cranial vault. Derangement of the cerebral circulation, septic influences and intracranial disease, are such causes.

2. The perceptive mechanism may be interfered with by adverse potentialities acting through the afferent nerves.

Let us consider first some of the data bearing on the second eventuality. When a person, seated in a revolving chair, is rapidly rotated he will experience, either during the continuance of such rotation or immediately upon its cessation, the characteristic symptom of vertigo. The occurrence of the phenomenon is not, however, due, as one might imagine, to the operation of the centrifugal force called forth by the rotation of the chair, but is to be ascribed largely if not entirely to the chaos engendered in the faculties of perception—general, and special also, if sight and hearing are operative—by the rapid and unusual change of place by the person experimented upon. I have been able to prove the truth of this proposition by reversing the experiment. Placing the subject in an armchair, I caused a cylindrical screen of white cloth 7 feet in diameter, suspended by a swivel from the ceiling, to rotate around him, with results identical as to character, but somewhat less in degree. In a word, vertigo usually supervened either during the rotation of the screen or immediately upon the cessation of such rotation. Naturally, such vertigo was only called forth when the eyes were open and the gaze fixed upon the rotating screen. Nor, as intimated, was it as intense as in the preceding experiment, when the subject himself was rotated; and for the very good reason, that under the last named circumstance—when the eyes are open—not only is common perception—muscular sense, etc.—but visual perception as well thrown into a condition of disarray, so that correct orientation on the part of the ego touching the topographical relations of the subject to environment is no longer possible. Surely, there can be no doubt as to the truth of deduction thus experimentally derived. Now, to take up the first eventuality—that in which vertigo is produced by intracranial causes—we find the phenomenon induced—the vertigo corresponds in all respects with that induced by the revolving chair and the revolving screen. There remains, then, no other conclusion possible than that phenomena thus identical must ultimately have a common origin. That common cause is perversion of perception, a perversion brought about in the one case through potentialities acting through the afferent nerves; in the other, by morbific elements acting upon the brain itself.

Concerning Certain Further Modifications of the Mental Faculties which Accompany Vertigo.—While, as previously shown, the proximal cause of vertigo is to be found in derangement of perception, this by no means represents the full extent of the psychical disorder. In all degrees of vertigo, but especially so in the severer ones, consciousness is always more or less impaired, such impairment being obviously the direct result of secondary confusional states engendered by the faulty percepts. Yet, while to the average physiological psychologist this secondary influence is certainly thinkable, there are—or were—not wanting some who obstinately held to the idea that in the milder forms of vertigo, at least, there was no impairment of the vividness of consciousness, nor of that alacrity of mind inseparable from vivid consciousness.

To set this matter at rest once for all, I determined, some time ago, to artificially induce rotary vertigo—the most typical form—and by noting the reaction time during the persistence of the vertigo, possess myself of infallible data on which to base a judgment.[1]

For the purpose of carrying out these investigations I designed and made use of apparatus, whose principal features are these:

An arm-chair (Fig. 1, *a.*) is supported in the center by a steel shaft, about two feet long, pointed at its lower extremity, to serve as a pivot. The shaft, at its upper end, immediately below the seat of the chair, passes through a steel ring, which receives support from a framework of iron bars (*b*); while, at its lower or pivoted extremity, a steel socket, set in the wooden cross, which serves as a base, affords the necessary fixation. Four feet from the chair, and appropriately supported by iron braces, is another shaft of steel, pivoted in like manner to that previously described, and surmounted by a wheel, provided with a crank handle (*c*).

The steel shaft supporting the chair and that surmounted by the crank wheel are provided, at their lower ends, a few inches above the wooden base, with sprocket-wheels, which in turn are connected by a stout chain.

---

[1] A preliminary report of these undertakings may be found in an illustrated article, published in the New York Medical Journal, Sept. 7, 1895.

From this disposition it follows that by turning the crank handle (*c*) it is possible to rotate the chair (*a*) at such speed as the exigencies of experimentation may determine. To enable the occupant of the chair to transmit the return signal to the recording apparatus (Fig. 3), I have devised the following arrangement:

Upon the cross-bar (*Fig. 2, e*) are fastened six stout copper springs *f*, which are, in turn, connected with an equal number of binding posts (Fig. 1, *g*). These springs impinge against six circular tracks of copper (Fig. 2, *h*) secured on the under side of the bottom of the chair. Each track is carefully insulated from its fellows, and is connected by means of a gutta-percha-covered wire with one of the binding posts (g^1 Fig. 1) on the side of the chair. From this disposition it is evident that the binding posts *g* are placed in direct communication with the binding posts g^1. Now it is clear that the recording apparatus (Fig. 3) can be attached by insulated wires to the binding posts *g*; and in the same way the simple key for returning the signal (Fig. 1, *i*) may be connected with the posts *g*. For the sake of simplicity, a resonant sound, like that produced by the stroke upon a bell (Fig. 3), may be employed to give the signal. The extra binding posts are for attaching the apparatus required for the determination of the discrimination time in vertigo. This question of discrimination time I shall, however, reserve for a subsequent paper.

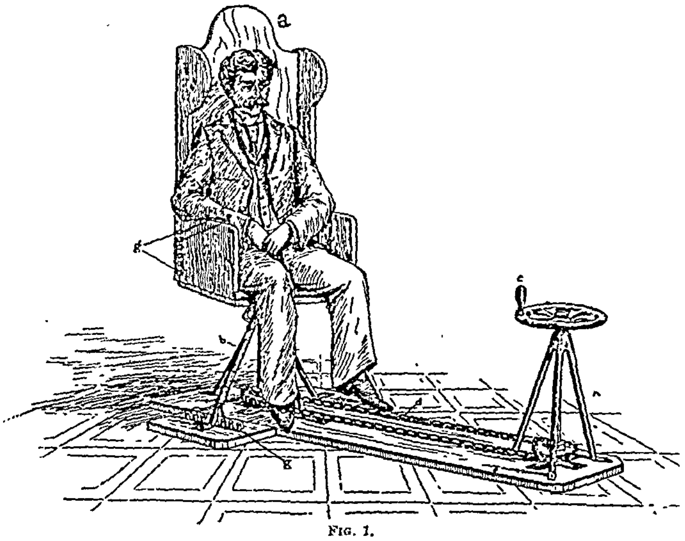

Fig. 1.

Figure 1.

The Reaction Time and Other Psychical Phenomena in Vertigo.—As some who read this may have forgotten the precise nature of what is known among psychologists and physiologists as reaction time, a word or two of explanation will perhaps prove acceptable.

It is a matter of experimental demonstration, as well as the result of ordinary experience, that mental processes of all kinds require a certain amount of time for their accomplishment. Moreover, the length of time consumed is in the direct ratio of the complexity of the mental act. To illustrate this point, let us assume that an impression is made upon the retina of the eye, and that as soon as that impression is perceived the subject presses upon the key of an electrical apparatus and so records the interval of time between the peripheral excitation and the issuance of the same in the purposive act—the so-called "reaction time." It will be found, as a result of a series of observations of this kind conducted by the aid of appropriate apparatus, that the average time in different persons is from one-tenth to two-twelfths of a second.

If, however, instead of making a single impression of uniform character upon the retina, we make heterogeneous ones, as when red and blue are displayed in indefinite order, and the subject is instructed to press the key only when the color red appears, the interval of time is at least twice as long. This additional consumption of time is due to the fact that not only is the mind obliged to take cognizance of the impressions, but to distinguish and select from them. Hence, the use of the term " discrimination time," to designate this more complicated variety of psychical reaction. As a matter of course, it is possible to determine the reaction time to touch, hearing, and sight; but in conducting such investigations it should always be remembered that the duration of the reaction period is markedly influenced by a variety of agents which interfere with the spontaneous and co-ordinate action of the cerebrospinal mechanism, and more especially of the brain. Thus the reaction time is shorter in health than in sickness, and it is longer after the ingestion of alcohol, ether, chloroform, or other agents which retard cerebral metabolism.

It follows, therefore, that by comparing the reaction time, after we have in some such way modified cerebral function, with the average normal reaction time, we shall, by a simple process of subtraction, be in a position to judge of the extent to which we have thus influenced the course of normal cerebration, particularly in its relation to the external world.

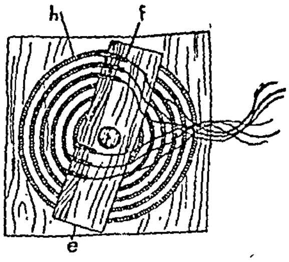

Figure 2.

To appreciate the wide significance of this fact, it must be borne in mind that the central elaboration implied by what is termed reaction time is essentially composed of the perception of a sensation originating from without and the formation thereupon of a definite volitional impulse.

The average values of reaction time are variously stated by different observers; in my opinion, those given by Waller are as nearly correct as any: to touch, 14/100 of a second; to sight, 18/100 of a second; to hearing, 16/100 of a second.

Various means of computing reaction time have been suggested and employed; that which consists in the use of an electromagnet, having upon its armature a pen to record upon a revolving cylinder the instant when a visual, touch, or auditory stimulus is applied, and the signaling (pressing of a key) by the subject when the stimulus is felt, is, in my opinion, the best.

As a result of numerous observations with this apparatus I have found that the reaction time in vertigo is increased to three-tenths and even four-tenths of a second, according to the intensity of the vertigo. I may add that this intensity is directly dependent upon the rapidity of rotation of the subject. It follows, therefore, that in the determination of the reaction time we have a means of ascertaining with scientific accuracy the degree of intensity of the vertigo. It would be a manifest omission were I not to mention that something may also be learned regarding the condition of the mind during vertigo by the aid of self-observation, though only when the rotations are relatively slow, since introspection is extremely difficult, if not absolutely impossible, when the vertigo is severe.

In this way a decided diminution in the power of attention may be observed; the subject is quite unable to carry on protracted thought so far as the analysis of external impressions is concerned; yet, in spite of all this, the power of introspection, or subjective analysis, remains but slightly impaired in minor degrees of vertigo. It is, however, curtailed and even entirely lost in severe vertigo. This loss of the power of introspection is the immediate precursor of absolute unconsciousness.

Finally, the ability to perform tasks necessitating rhythmical and delicate motor co-ordination, as in playing upon a musical instrument, is lost in the severer degrees of vertigo. It is true that it is often possible to execute a series of automatic or semi-automatic acts, as exemplified in a simple scale; but to play a composition necessitating a conscious demand of memory, or to improvise, is out of the question. This point I have tested in both violin and flute players.

In conclusion, it may be said that while there is a certain obtunding of sensibility in the severer degrees of vertigo, complete analgesia appears only with the advent of total unconsciousness.

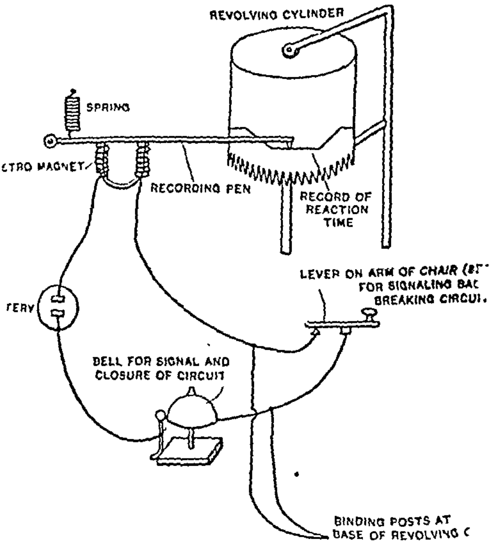

Figure 3.

Physical Phenomena Present in Rotary Vertigo.—But the reaction time is by no means the only phenomenon of which we are able to take cognizance by the aid of the rotary chair. In the first place, since the vertigo persists for a short time after cessation of rotation, it is possible to make some observations as to the subject's physical condition. Acting upon this principle, I was able to ascertain that in vertigo of moderate intensity the pulse, while somewhat increased in rapidity, is diminished in fulness. I have also observed a diminution in the rapidity of respiration; but this is not a constant phenomenon.

Again, when the vertigo is severe, the inhibitory effect of the brain upon the spinal cord is diminished to such a degree that reflex action, and especially the patellar tendon reflex, is decidedly exaggerated. There is likewise diminished vigor of voluntary muscular contraction, as shown by the dynamometer.

Finally, in severe vertigo there is apt to be a facial pallor accompanied by a marked dilatation of the pupils. Nausea, too, sometimes occurs, especially when the eyes are fixed upon surrounding objects. The last-named symptom may be avoided to some extent, by darkening the room, so that the surrounding objects are no longer visible. It is noteworthy, too, that when the object looked at it fastened to the chair, so as to revolve with it, nausea is much less readily induced.

Suppression of Vertigo Through the Monopolization of the Field of Consciousness by Vivid Sense Impressions, Particularly Those of Hearing.—There is one other suggestive and curious fact, which I have ascertained with regard to rotary vertigo, which I can not forbear communicating to you, before leaving the purely experimental side of the inquiry.

Knowing the importance ascribed—erroneously I think—to the inner ear as a part of the mechanism of equilibration; the thought occurred to me one day, to fasten a phonograph to the back of a revolving chair, and, connecting the instrument with the ears of the person experimented upon by india-rubber tubes, note any possible effects produced upon him by musical vibrations during the revolution of the chair.

Fancy my astonishment, when, after the very first attempt, the person experimented upon, a man of veracity and judgment, declared that, during moderately rapid rotation, he experienced no vertigo whatever. When, however, during the next experiment, I asked him to suddenly remove the tubes from his ears, while the chair was rotated, he declared that the vertigo immediately made itself felt with full intensity.

Wishing to determine whether such an inhibitory effect was alone obtainable through the sense of hearing, or whether the like might be brought about through vision, I removed the phonograph; had the subject hold an electric light of ten candle power in his hand and fixedly regard it while the chair was rotated at moderate speed.

Again, to my considerable surprise, he declared that he felt practically no "dizziness," although the inhibitory effect did not seem quite as pronounced as that obtained by sound impressions. I may add, as the result of further observations, that vertigo of moderate intensity only is thus capable of sensory suppression. Moreover, the acoustic and visual excitation should be intense in character—the musical vibrations loud, strident, the object looked at bright, dazzling.

These observations dispose utterly, in my judgment, of the old theory which assigns special importance to certain portions of the inner ear in connection with equilibration.

With regard to the suppression of the vertigo through vivid impressions of sight and sound, particularly the latter, the explanation is not far to seek. The morbid percepts engendered by rotation, that under ordinary circumstances would have culminated in the production of vertigo, are overborne by the vivid sense of impression, submerged, as it were beneath the vastly more intense percepts of sight or sound, which monopolize the field of consciousness completely.

Only when, as in the extreme degrees of rotary vertigo, the morbid percepts rise to such a degree of intensity as to defy neutralization, do the acoustic and visual impressions fail to inhibit.

From the foregoing experiments, which are unique in medical literature, and which offer indeed, the only means of scientifically determining very much about the nature of the phenomenon under consideration, I have felt justified in deriving the following conclusions:

1. That vertigo is primarily a derangement of perception, if a sufficiently expansive meaning be given to

the term to also include morbid impulses transmitted through afferent nerves other than those of special sensation.

2. This derangement of perception is, however, always accompanied by some impairment of consciousness.

3. This impairment of consciousness, as declared by the lethargic reaction-time and by introspection, is undoubtedly due to the confusional conditions engendered in contiguous centers of higher mental action—cortical centers, according to current physiological opinion—by the advent of the faulty percepts.

4. Vertigo may, however, be engendered by direct impairment of the functional efficiency of the centers of perception, without the intermediation of the afferent nerves. On this admission only is the vertigo accompanying auto-intoxication and that associated with intracranial disease to be accounted for.

5. Though the clinical causes of vertigo seem, at first view, irreconcilably disparate, they have at least this in common, that they one and all are capable of interfering either directly or indirectly (reflexly) with cortical function, with consequent impairment of consciousness.

6. To regard vertigo as essentially a cortical derangement, of either direct or indirect origin, accords, therefore, with the experimental data and is clinically explanatory.

7. Rotary vertigo—but only of the milder sort—may be more or less inhibited by vivid impressions, particularly those of sound, which outweigh—submerge as it were—in consciousness the vertigo, or rather the perverted percepts, which are its essential essence.

8. Finally, the impairment of consciousness, due to interference with cortical function, is in the direct ratio of the intensity of the vertigo.

Therapy.—The rather lengthy analysis, which has led up to these conclusions, has made, I fear, somewhat undue demands upon attention and time alike. I have chosen, however, rather to incur the risk of some blame on the score of prolixity than to affront scientific fitness by an empty *ipse dixit*. To have acquired, indeed, some insight into the real nature of the phenomenon we are considering; to be able, hereafter, to replace crass empiricism by rational management; to acquire, in a word, some mastery in what is concededly a baffling field, has seemed to me well worth the trouble it has cost.

If there is one thought more vividly suggested by these researches than any other it is this: That in so far as the abatement of the symptom itself is concerned, the vertigo, in short, our efforts should be immediately addressed to the cortex. Only by diminution of the susceptibility of that region to irritative influences, whether from without or within—whether due to fluctuations of the cerebral circulation, or to the presence of intracranial disease, or toxic elements in the blood, or disturbing influences transmitted through the afferent nerves—only, I repeat, by obtunding the irritability of the cortex can we hope to render the supervention of vertigo impossible, or if not altogether impossible at least unlikely.

Is this deduction, derived wholly, as it is, from pure theory, capable of further and more convincing demonstration? Or to come to the point in a few words, is the conclusion buttressed likewise by the laboratory and by the clinic?

This question I have sought to answer by experimentation on the one hand, and by an inquest into the therapeutics of vertigo, due to various pathological causes, on the other. To meet the inductive exactions of the problem, I have invoked the services of a rotary chair, which has figured so prominently in the previous experiments. Determining by the number of rotations to the minute the exact degree of vertigo it was proposed to induce, I was able to compare the sensations of the subject before and after medical interference.

The first subject, a man peculiarly susceptible, was given 40 grains of potassium bromid at 8 a.m.; at 12, this dose was repeated, with the result that shortly thereafter he displayed hebetude and marked somnolence. Hereupon, having placed him in a chair, I rotated the latter at precisely the same speed as before the ingestion of the bromid; but to his astonishment and my own gratification he declared that he experienced no "dizziness." I then considerably increased the number of rotations, but without manifest effect. Since this first and quite convincing observation, I have made similar tests with moderate inhalations of ether, nitrous oxid, and with the internal exhibition of chloralamid and trional; and while the results obtained from the last two remedies were not as striking as one might perhaps have anticipated, those from the inhalation of nitrous oxid and ether were quite satisfactory, the vertigo being practically entirely suppressed while they were exhibited. The essentially complete accord existing between these results of laboratory work and those obtained in the clinic is certainly striking. Glance through the published statistics, and con over your own experience, and you can not fail to be impressed by the fact that those remedies are most effective which, by general admission, exert a pronounced sedative effect upon cerebration, upon that higher mentalization which current physiological opinion regards as wholly, or almost wholly, traceable to cortical action—belladonna, opium, the bromids. Many can recall vividly enough, no doubt, cases of vertigo, whose very causation was a mystery, yet, cases nevertheless, in which these remedies, empirically administered, perhaps, and without even a pretense of analysis, served completely. It is, of course, not to be forgotten that what we are here principally concerned with is the symptomatic management of the affection.

When, on the other hand, we attack the problem of radical cure, of eradication of the exciting cause, we find ourselves immediately confronted by various and complicated difficulties, whereof the exhaustive consideration would require a great deal more space than that available in a paper of the compass of the present writing.

If there be feeble heart-action with consequent irregularity and lethargy of the cerebral circulation, you will think of nitroglycerin, strychnin, digitalis and other remedies of which they are the prototypes.

To combat those stomachic derangements which are such a common cause of vertigo, you will have a wide choice of expedients, to the use of which your broad experience and common sense will show the way. So, too, with the toxic varieties of the affection—those largely due to inefficiency of the excretory apparatus. Here, again, your knowledge of general medicine will stand you in good stead, both in arriving at a correct diagnosis, and deciding the question of diet and medication.

Sometimes, however, matters are not so obvious. Cast about with what diligence one may, the exciting cause refuses utterly to reveal itself. In such cases, careful attention to the condition of the eye and ear, especially of the eye, may bring the necessary information, with consequent enhancement of the chances of complete relief. Would that the opportunity of successfully coping with the affection were always as favorable! Unfortunately, as already remarked at the beginning of the argument, vertigo is not infrequently the consequent of grave organic disease of the central nervous system or of important viscera—notably of the kidney and liver. Aside from the palliative treatment usual in such cases, we may profitably seek to cope directly with the vertigo itself, along the lines already fully indicated. Indeed, it is precisely in such discouraging dilemmas that a rational insight into the true nature of the symptoms will be found most useful.

53 West 38th Street.

DISCUSSION.

DR. A. L. BENEDICT, Buffalo, N. Y., said that while this paper might equally well have been read in the Section on Physiology, it is a very valuable contribution to the study of therapeutics and, therefore, appropriate. He approves of the attitude of the writer as to the organs of special sense. There has been nothing more beautifully demonstrated in physiology than that the semicircular canals are organs of equilibrium. He was astonished to hear the reader of the paper attack the accepted view as to the action of the semicircular canals, and cited, in illustration, a personal experience: Recently, during a journey, he spent part of the night in meditating on the wonderful mechanism of the semicircular canals. When he awoke in the morning he discovered that what he thought was the front of the car was the rear and that the car was going in the contrary direction to that which he had thought. Similar experiments have made him sceptic with regard to the semicircular canals. He thinks that many of our ideas of equilibrium come from the liver. For instance, in going up and down in an elevator, the feeling is referred to just below the diaphragm. He was glad that the lecturer had taken away the old view as to the function of the semicircular canals—it is a beautiful theory, but it is not well substantiated.

DR. W. B. HILL, Milwaukee, Wis., said that the reader of the paper had illustrated the fact that all treatment should be based on physiology, which alone affords a rational basis for therapeutics.

THE PHARMACOLOGIC ASSAY OF DRUGS AND ITS IMPORTANCE IN THERAPEUTICS.*

E. M. HOUGHTON, M.D.

Lecturer on Experimental Pharmacology, Detroit College of Medicine.

DETROIT, MICH.

NOTE.—The word "pharmacology" is employed as meaning "the study of the changes induced in living organisms by the administration in a state of minute division of such unorganized substances as do not act merely as foods."

After a correct diagnosis has been made, one of the most important questions to be considered by the physician is that of dosage. Especially is this true when, as often occurs, the patient's life depends upon prompt and efficient aid. But if the drugs prescribed are not of fixed and definite strength our efforts may prove utterly unavailing.

Until a few years ago we were obliged to employ pharmaceuticals of uncertain and varying strength. This variation was due not alone to differences in the process of manufacture, but also to the fact that the amount of active constituents contained in the crude drug itself varies from season to season, is modified by habitat, climatic influences, method of collecting, curing, handling, storing, etc. Where the active principles only are employed, the dose can be fixed exactly. In the case, however, of certain important drugs, such as the heart tonics, ergot, etc., a chemical assay is impossible with our present technique, owing to lack of knowledge of the active principles and of their therapeutic value, as well as to the ease with which chemical break-down occurs. Hence the question arises: "If chemical assay fails to give accurate data relative to the pharmacologic activity of a drug, by what method or methods may such information be obtained?" During the past six years I have been trying to answer this query, and desire at this time to consider briefly some of the methods of pharmacologic assay, the results obtained, and the clinical value of the drugs experimented with.

Of the many theories offered to explain the reactions between the elements of the animal body and drugs, chemical affinity seems the most plausible—the normal function of a given organ being altered in degree by the union occurring between the protoplasm of its cells and the given drug.

It is important in making comparisons of the results obtained from the administration of drugs to animals that the following be kept in mind: Since different species of animals react differently to the same drug, as they do to the same species of bacteria, it is necessary to determine by numerous experiments the type of animal best suited for the assay of each drug.

The animals employed in any pharmacologic test must be as nearly as possible of the same species, age, weight, sex, and general physical condition. The conditions obtaining in the experiments should always be constant as regards environment, food, method and time of administering the drug, length of time for making observations, reading and recording results, etc. Animals, during the time of experimentation, should be kept as nearly as possible in the natural condition. The method of administering the drug should be the one that will allow the greatest rapidity and certainty of absorption and produce the least harm to the animal.

The activity of the tested drug should be compared each time with a standard preparation which represents the active properties of a drug of average quality; the strength of the standard being determined by assaying a large number of samples obtained from different sources.

A sufficient number of animals should be employed in each test to determine the average reaction of a normal animal. Drugs should be given to animals in proportion to their weight and general physical condition. As great care should be exercised in carrying out the several steps of a given assay as in making a chemical determination.

Pharmacologic action is quantitative; in other words, the physiologic processes of the animal body are altered in degree, but not in kind, by the influence of drugs. This fact is more clearly demonstrated in healthy than in diseased subjects, the disease process or processes present often causing great variability in therapeutic results. If we could always get our tubercle cases at exactly the same stage, and if diphtheria always meant the presence of the same number of diphtheria germs, of the same virulency, and producing toxins of the same strength, etc., therapeutics would become more exact, provided our drugs were uniformly active.

Abundant evidence has been adduced to demonstrate the quantitative nature of pharmacologic reactions in normal animals. In some instances the means available for recording pharmacologic changes are more exact than in others, consequently the limits of error will be greater with some drugs than with others.

The reaction upon which to base a pharmacologic assay differs according to the nature of the drug. The minimum fatal dose, the amount of protection conferred against a poison, change in blood-pressure, general or special change in the physical condition, etc.—any one of these may be in particular instances utilized to fix the standard of strength.

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The following illustrations will demonstrate the reliability of pharmacologic methods as a means of determining the degree of activity possessed by a given drug. At the meeting of the Association in Denver, I gave in some detail a method for assaying strophanthus and the other heart tonics by determining the minimum fatal dose for frogs. Since then I have had abundant opportunity to verify the reliability of the method. Three tinctures of strophanthus of unknown strength which had been colored to exactly resemble each other were recently referred to me for assay. These were numbered 1, 2, and 3. In order to check the results obtained, three tinctures were prepared from these, as follows:

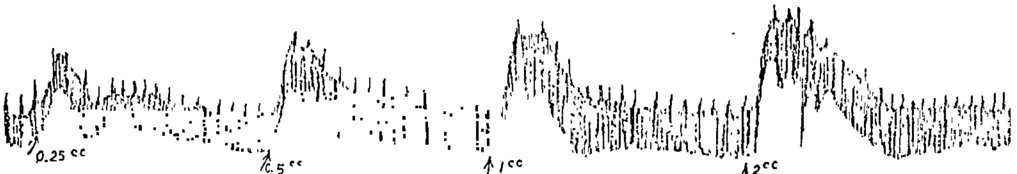

Fig. 1.—Blood-pressure tracing taken from the carotid artery of a dog anesthetized with chloretone. The suprarenal liquid was diluted with normal saline solution to 5 c.c. in each instance, and slowly injected into the femoral vein.

No. 4 = 5 c.c. of No. 1 + 3 c.c. standard tincture + 2 c.c. alcohol.

No. 5 = 5 c.c. of No. 3 + 3 c.c. standard tincture + 2 c.c. alcohol.

No. 6 = 5 c.c. of No. 1 + 5 c.c. of No. 3.

The following table gives the results reported by my assistants:

No. 1 = 50 per cent. reported strength of standard tincture of strophanthus (standard tincture of strophanthus = 0.00015 c.c., the minimum fatal dose per gm. for test frogs). Mogk.

No. 2 = 100 per cent. standard tincture. Mogk.

No. 3 = 150 per cent. standard tincture. Mogk.

No. 4 = 57 per cent. standard tincture. Actual strength 55 per cent. Variation 2 per cent. Hamilton.

No. 5 = 107.5 per cent. reported strength of standard tincture. Actual strength 105 per cent. Variation 2.5 per cent. Mogk.

No. 6 = 100 + per cent. reported strength of standard tincture. Variation less than .5 per cent. Hamilton.

The above table shows that two men assaying tinctures of strophanthus of unknown strength by the use of frogs are able to obtain results showing a maximum variation from the actual strength of only 2.5 per cent. Similar results have been again and again obtained by the application of this method.

Abel and other workers claim that the active principle of suprarenal glands, producing hemostasis when applied to mucous membranes, when injected into the circulation produces marked temporary rise in blood-pressure. That this rise in blood-pressure varies with the amount of extract injected is well shown in tracings Nos. 1 and 2, while tracing No. 3 gives the results obtained from investigation of a complaint that a certain shipment of glands from a packing house was not the genuine article. The tracings were obtained from the carotid artery of dogs anesthetized with chloretone. Microscopical and macroscopical examination showed that the complaint was well grounded, the glands being thymus instead of suprarenal. Here we have an instance of undoubted quantitative reaction from the administration of an animal substance to an animal. The details of this work are to be given in a subsequent paper.

Probably the most complicated of pharmacologic assays is the one with which the medical profession is most familiar. I refer to the assay of antidiphtheric serum by the determination of the smallest amount of serum that will neutralize a given quantity of diphtheria toxin.

The question has been raised as to whether this should be called a pharmacologic assay. It seems to me there is no ground for objection to such a classification, as both the toxin and antitoxin are "unorganized substances which produce changes in living organisms and do not act merely as foods"; moreover, the bouillon containing the toxins formed by the germ is comparable to a tincture of nux vomica or other drug, as both are solutions containing the products of vegetable cells in solution. In the one case we have the products of a plant composed of a great many cells working together; in the other instance the products are formed by many isolated vegetable cells. The antitoxin also resembles the suprarenal gland extract in that both are the products of animal cells. The medical profession the world over are agreed that antitoxin can only be assayed by experiments upon animals. In standardizing antitoxin by any of the methods now in use, at least three factors cause a variation in the results, viz., variation in the strength of the toxin, which gradually becomes weaker; variation in the strength of the antitoxin, which also gradually becomes less potent; and variation in the reaction of the guinea-pig to the toxin and antitoxin. On the other hand, in pharmacologic assay of plant drugs, only one variable factor is present, the test animal, since, as a rule, the drugs themselves retain their active properties unimpaired for a sufficiently long time to allow an assay to be made.

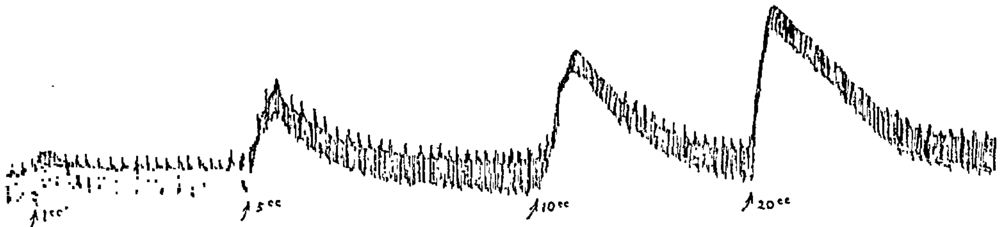

Fig. 2.—Blood-pressure tracing obtained in the same manner as No. 1. Suprarenal liquid solution was, however, more dilute than that employed in No. 1.

Other examples might be cited, but surely a careful consideration of the above results should carry conviction to an unbiased mind that it is possible to determine the pharmacologic strength of drugs from their action on the lower animals.

That, in the absence of pharmacologic assay, great variation exists in the strength of certain drugs, has been demonstrated over and over again by the physician at the bedside. One can appreciate the necessity for such an assay if it is remembered that some of the most powerful poisons known belong to the class of drugs which do not admit of chemical assay. Only a short time ago I found three samples of tincture of strophanthus, purchased in the open market, to be of the relative strength of 1 to 3 to 5. Yesterday one digitalin —Germanic—was found twice as strong as the same preparation from a different manufacturer. Tracing No. 3 indicates what might happen in the case of preparations from the suprarenal glands. Many other instances of variation in strength might be mentioned much more startling than these, some of which have been reported previously; but multiplicity of illustrations is not necessary to prove the necessity of employing, as far as possible, drugs that have been chemically or pharmacologically assayed in the treatment of disease.

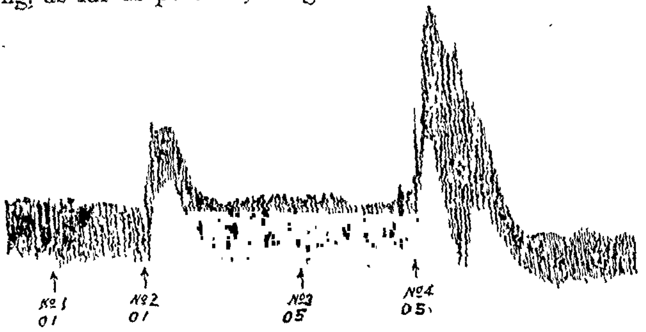

Fig. 3.—Blood-pressure tracing taken from the carotid artery of a dog. No. 1, result obtained from the injection into the femoral vein of a 0.1 c.c. of the extract submitted for assay; No. 2, result obtained from the injection of 0.1 c.c. suprarenal liquid; No. 3, result obtained from the injection of 0.5 c.c. of extract submitted for assay; No. 4, result obtained from the injection of 0.5 c.c. of suprarenal liquid with chloretone.

DISCUSSION.

DR. A. B. LYONS, Detroit, Mich., questioned the propriety of discussing a paper when the author was not present to defend it.

DR. LEON L. SOLOMON, Louisville, Ky., said that the paper raises the question on which the Convention for the Revision of the Pharmacopeia, at its last meeting, needed some light. It rejected all formulæ for standardizing by physiologic assay. The chairman of that convention did not think it was possible to standardize drugs by physiologic tests.

DR. LYONS said that he represented the chemical assay of drugs, as his experience had been in this line of work particularly, so that he would not assume to decide on the value of the physiologic assay of drugs. He would, however, state that, *generally* speaking, there is not a single chemical assay practiced that can give exact valuation of the physiologic or therapeutic effect of the drug in question, except perhaps in the case of opium. He thinks, therefore, that the chemical processes may well be supplemented by physiologic tests. He wishes to be distinctly understood as favoring the supplementing of chemical by pharmacologic tests, and insists that many of the drugs, especially animal extracts, can never be standardized in any other way. He can not understand, therefore, why the convention on revision of the U. S. Pharmacopeia so positively refused to adopt any pharmacologic tests. He said that he would endeavor to have this unreasonable taboo removed in future conventions.

DR. LEON L. SOLOMON, Louisville, Ky., said that it seemed to him that there was some sort of pressure exerted at the pharmaceutical convention against these pharmacologic tests, and that those who were most active by reason of their pressure at former pharmacopeial conventions, by their knowledge of the customs and methods, had succeeded in preventing proper consideration of this subject.

DR. C. T. MCCLINTOCK, Detroit, Mich., said that the physiologic action of a drug is not a question of opinion, but one of fact. In the case of the organic extracts this is the only possible way of proving their activity. Chemical assays may be criticized, but the rise in blood-pressure from the effects of suprarenal extract, for instance, is a matter of demonstration.

THE UNITED STATES PHARMACOPEIA OF 1900.*

PROF. JOSEPH P. REMINGTON, PH.M.,
PHILADELPHIA.

The United States Pharmacopeia occupies a unique position among the pharmacopeias of the world. Its authority is established throughout the country, mainly through the voluntary assent of the physicians and pharmacists of the United States.

It is true that the government is represented in the convention through the Departments of the Army, Navy, and Marine-Hospital Service, and the custom houses recognize the work in their regulations for the admission of drugs into the country; many of our state laws acknowledge the authority of the book by demanding a compliance with its established standards; but the fact remains that the work is not revised or published by the government, but through a representative body of physicians and pharmacists assembled in convention every ten years in the City of Washington.

The thoroughly republican method of reaching the consensus of opinion in both professions, in giving expression of these by the decennial revisions of the book, exhibits one of the best examples of effective submission to authority and is typical of the highest form of citizenship in a modern republic.

European pharmacopeias are government books and have behind them the weight of authority which the laws of the country demand. For many reasons it must be regarded as more than desirable to continue the American method of revision and publication as long as possible, and it is likely that no change will be made so long as wise, conservative and progressive counsels govern the controlling body.

The Pharmacopeia of 1890 was received, not only in this country, but abroad, as a work fully equal to any published in the world, and it is sincerely hoped that the professions of medicine and pharmacy will give to the new committee of revision appointed last month, that loyal support which was so generously extended to the old committees in former years; as is well known, the decennial convention assembled on May 2, 1900, in Washington; delegates were present from every part of the Union. Twenty-eight states were represented by delegates from various medical and pharmaceutical bodies; national organizations were represented through the AMERICAN MEDICAL ASSOCIATION and the American Pharmaceutical Association; while the government sent accredited delegates from the Army, Navy, and Marine-Hospital Service.

Medicine and pharmacy were about equally represented; fifty-seven medical colleges, medical departments of universities and state medical societies sent delegates; while fifty-nine colleges of pharmacy, pharmaceutical departments of universities and state pharmaceutical societies sent delegates.

It will be seen that the convention was a thoroughly representative one; this is further shown by the officers selected to preside over the deliberations, which were as follows: President, Dr. Horatio C. Wood, of Philadelphia; vice-presidents, Profs. A. B. Prescott, of Ann Arbor, Mich.; O. A. Wall and Drs. R. W. Wilcox, of New York, N. S. Davis, Jr., of Chicago, and A. L. Langfeld, of San Francisco; secretary, Dr. H. M. Whelpley, of St. Louis; assistant secretary, Dr. W. G. Motter, of the District of Columbia, and treasurer, Dr. Wm. M. Mew, of Washington.

---

* Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

It will thus be seen that the officers represented the different sections of the country. The committee of revision, consisting of twenty-six members, was selected without geographical considerations, but solely with the purpose of selecting men who were regarded by the convention as fitted by training and technical knowledge to revise the work. Charles Rice, of New York, was unanimously re-elected chairman. Philadelphia is represented by six members, as follows: Drs. H. C. Wood, H. A. Hare, John Marshall, Professors Remington, Sattler and Kraemer; New York by six members, Drs. J. J. Abel, R. W. Wilcox, Profs. Virgil Coblentz, Gregory, E. H. Squibb and the chairman; Boston has but one member, W. R. Scoville; Baltimore, two members, Professor Caspari and Dr. Dohme; Chicago has four, Drs. N. S. Davis, Jr., and W. S. Haines and Professors Oldberg and Hallberg; St. Louis, Prof. James M. Good; Atlanta, Dr. George F. Payne; Madison, Wis., Professor Kremers; Lawrence, Kans., Prof. L. E. Sayre; Ann Arbor, Mich., Prof. A. B. Stevens; and Louisville, Prof. C. Lewis Diehl.

A constitution and by-laws were adopted at the last convention which will place the work on a more stable basis than ever before. Important changes were made in the general principles to be followed in the revision of the next Pharmacopeia, the most prominent of which are as follows:

The Committee of Revision is authorized to admit into the Pharmacopeia any product of nature of known origin; any synthetized product of definite composition which is in common use by the medical profession, the identity, purity or strength of which can be determined. No compound or mixture shall be introduced if the composition or mode of manufacture thereof be kept secret, or if it be controlled by unlimited proprietary or patent rights.

After each pharmacopeial article—drug, chemical or preparation—which is used or likely to be used internally or hypodermically, the committeee is instructed to state the average approximate—but neither a minimum nor a maximum—dose for adults, and, where deemed advisable, also for children, in the metric system, with the approximate equivalent in apothecaries weights and measures. It is to be distinctly understood that neither this convention nor the committee on revision created by it intends to have these doses regarded as obligatory on the physician or as forbidding him to exceed them whenever in his judgment this seems advisable. The committee is directed to make a distinct declaration to this effect in some prominent place in the new Pharmacopeia.

Probably the most important work, so far as the Section on Materia Medica is concerned, is the change of policy above outlined with reference to synthetic remedies. The Pharmacopeia could never be regarded as abreast of the times if such remedies were entirely excluded. It is not the purpose of the writer to argue this much-mooted question, but the action of the committee must be regarded as wise and just.

No Pharmacopeia in the world is justified in opening its pages and giving the weight of its authority to chemicals or preparations whose formulas are secret or so controlled that their identity, purity or strength can not be determined.

It is possible that this rule may seem to work an injustice to a manufacturer who has secured a wide acceptance of his product, but who chooses for commercial reasons to keep his process or the composition secret. But, on the other hand, to open the door to one preparation which did not fall within the rule would necessarily mean the admission of an enormous flood of remedies more or less unstable in popularity and without those elements which would make a remedy useful for ten years.

Although previous conventions voted down the resolution to introduce doses into the work, the convention of 1900 was compelled to recognize the almost universal demand for this innovation; under the limitations indicated in the previous paragraph, it must be admitted that the introduction of doses will be shorn of its dangers.

An interesting discussion took place at the last session of the convention, and a resolution passed, which plainly indicates that the convention desired to have the widest publicity given to the authority of the work and no restrictions should be placed upon the proper use of the text of the book; of course the copyright will be guarded as heretofore, so as to prevent the republication of the book in its original form, but inasmuch as its authority depends largely upon the consent of "the governed," the greater publicity given to Pharmacopeia formulas must tend directly toward a general adoption of its formulas and processes.

In conclusion it may be stated that a very successful meeting was held and there is every reason to believe that the Pharmacopeia of 1900—which will probably see the light in three years from now—will be received with the same welcome which has been loyally accorded to its predecessors.

DISCUSSION.

Dr. Leon L. Solomon, Louisville, Ky., said that the wisdom of the last revision committee is very prominent in relation to the question of the introduction of doses into the United States Pharmacopeia. He recalled having seen, recently, a number of reports from societies to which the question was submitted: "Shall the Pharmacopeia prescribe doses?" This is a very important question, since there may be law-suits for damages in case some physician wished to overstep the dosage laid down by the Pharmacopeia. Therefore, he is glad to hear that the revision committee resolved to put down the average dose, but not to restrict it by giving a maximum, which properly should be left to the individual physician. The question with regard to patented synthetic articles is also important. The idea seems to be that the door should be open for the limited reception of these drugs. In the resolution passed in this Section, last year, we did not confine ourselves by words, but expressed the opinion that patented synthetics should be admitted to the Pharmacopeia, without stipulating that such articles should be in general use. This wording is surely a wise one and is worthy of the committee, which has also shown its wisdom in other directions.

Dr. A. B. Lyons, Detroit, Mich., said that, with regard to the introduction of doses of drugs, he has somewhat different views from those which prevailed in the convention. The view he entertains is that the pharmacopeia is the only authoritative standard we have in relation to drugs, in this country. Questions are continually arising as to maximum doses. While it should be left to the physician to use any dose he chooses, yet some authority should lay down some limit, so that the dangerous doses may be known. Then, if the physician has occasion to exceed that limit, he should be required to show by some mark or sign that he assumes the responsibility of the excessive dose. This is necessary for the protection of the druggist. At present the prescription comes into the pharmacy and there is no authoritative statement as to what is a dangerous dose of the agent.

The druggist knows that physicians are sometimes absent-minded, and is unwilling to put up the prescription without consulting the prescriber, and this involves delay in a case where moments may be precious. Again, if there were a standard and the druggist puts up a dangerous dose, he can be blamed for it, but if there is no standard, he can lay the blame on the physician.

Prof. J. P. Remington, Philadelphia, said that the last speaker is the author of a work on assaying of drugs, and with a chemist's demand for exactness, he desires everything reduced to a certainty. However, we know that doses can never be certain quantities. Suppose, for instance, the Pharmacopeia states that ⅛ gr. of morphin is a safe dose; every physician knows that this dose must be exceeded in many cases and, while it would be desirable for some reasons to admit doses to the U. S. Pharmacopeia, yet it might be a source of great inconvenience in actual practice. For instance, a druggist seeing an unusual dose may delay the compounding of a prescription and cause the death of a patient. He would like to ask how many physicians would engage to *always* indicate an unusual dose, by underscoring or other means, he might do it in many cases, but at some time he would be sure to overlook it and cause trouble and delay. Such a rule would also put it in the power of pharmacists to annoy the physician in a very disagreeable way, by returning a prescription, especially if he has law and authority behind him. He wished to remind the Section that for thirty years the druggists have been trying to get doses into the Pharmacopeia, and that thus far the effort has been successfully resisted by the physicians. The only way in which they can safely be introduced into the Pharmacopeia would be with the understanding that they are not to be regarded as authoritative, and this is practically what the convention ordered the committee to do, for the next Pharmacopeia.

ASTIGMATISM, ITS DETECTION AND CORRECTION.*

H. BERT. ELLIS, M.D.
LOS ANGELES, CAL.

From the standpoint of an oculist, astigmatism is that difference in the curvature of the meridians of the refracting media of an eye which causes rays of light from a point after being refracted to be focused in a line, oval or circle, but never in a point. In examining the refraction of such eyes, it is seldom necessary to study more than the meridians of greatest and least curvature, the so-called principal meridians, which are, as a rule, at right angles to one another. When the error of refraction for these has been corrected, it is corrected for all meridians excepting in cases of irregular astigmatism. Astigmatism may exist in the cornea alone, in the lens alone, or in both, while that of the cornea may be augmented or neutralized by that of the lens. We are, consequently, obliged to take under consideration the radii of curvature of the principal meridians of the whole refractive system in fitting glasses for the correction of this defect.

What method or methods shall be used to detect the full amount of astigmatism in any given eye? This is the question over which the beginner in refraction stumbles most. The methods may be divided into two broad classes: Subjective and objective, and they must be use din conjunction for the best results. Personally, I believe it best to obtain the corneal astigmatism first, and this may be measured accurately and quickly by means of an ophthalmometer, of which there are many varieties on the market, and it would be presumption on my part to say which is best. They are nearly all accurate, and so will fulfil the purpose for which they were invented. How useful is the ophthalmometer? Is it of any use? Is it not, indeed, more harmful than useful? Are not its readings more frequently misleading than time-saving? All these questions have been and are being asked of me by the young practitioner and by those who know nothing of its use except from literature. My answer has been in the great majority of cases, "I find it useful and a great saver of time." While the information gained is sometimes misleading, it is seldom so, and as a time-saver in refracting it is to me a great factor, although I should never prescribe cylinders from the ophthalmometer readings alone.

Of all methods of measuring the total amount of astigmatism certainly the most accurate, after the details of the method have been acquired, and undoubtedly, the most satisfactory to the operator, is skiascopy or retinoscopy. The patient's eyes, however, must be completely under the influence of a cycloplegic. The use of the plain mirror, the source of illumination, close to the operator's eye at a distance from the patient of 1 m., is perhaps the most satisfactory working distance and method. By this method you not only obtain the full amount of astigmatism, but also whatever other refractive error exists.

The ophthalmoscope is used to detect astigmatism, both by the direct and indirect methods, but I am free to confess that personally I should not be able to prescribe from the knowledge gained by this method, and I have always doubted the integrity of those making claims to be able to diagnose accurately low amounts of astigmatism existing in any given eye by this method.

The direct method is used by noting the difference in the strength of the glasses used to bring out distinctly the horizontal and vertical vessels in the region about the macula. The indirect method is hardly worthy of passing notice, because it is not exact and the error must be large in order to be recognized at all.

Of the subjective methods, where we depend on the answers of the patient for our information, it is hard to say which is the best, the quickest, and at the same time the most accurate. In fact, all the subjective methods are more or less slow and, at the same time, more or less inaccurate.

The old stenopeic slit method, which has almost gone out of date, has some points of excellence which make it worthy of more use than it has of late received. The fact that an astigmatic eye is able to distinguish lines which run in the direction of the focal line has been the cause of many methods being invented embodying the principle of the stenopeic slit. Dr. Edward Jackson has for years used a circular card with three parallel 2 mm. black lines with two spaces of the same width, pivoted to a disc with degree marks. Dr. James Thorington has, within the past year, called the attention of the medical profession to his pointed line test, which consists of a series of one-minute black squares, in two sets of three parallel lines at right angles to each other, mounted on a pivot and run by clock work. The perforated disc test and the Hotz test have the same principles involved. Pray's letters are too confusing as a rule to be of great practical value. The astigmatic chart, as typified by the clock face, is also going out of use very largely, except for verification.

The cobalt-blue or chromo-aberration test has some points of advantage as an ametropic test. By it the oculist may be enabled to tell at once the nature of the patient's refraction, but not the exact correction or angle of the astigmatic error.

The subjective test, which is the final court of appeal, is the trial lenses, and these are more or less involved in all the other subjective tests.

---

* Read by title, in the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

As to the correction of astigmatism, just so much of the error should be corrected as can be worn with comfort after a few days exercise with the correction. If a compound error, where the myopia or hypermetropia and the astigmatism are of about equal amounts, the astigmatic error is of the greater import, and the ametropic conditions may be best corrected and the symptoms sometimes completely relieved by correcting the astigmatism alone; whereas, the correction of the hypermetropic or myopic error alone would leave the patient in just as great suffering as before the correction. In cases where the hypermetropia or myopia is much greater than the astigmatic error, the correction of the astigmatism alone would be of little value. So, in these cases, a portion of the hypermetropia or myopia must be corrected with the astigmatism. Where large errors of astigmatism exist and there are no symptoms referable to the eyes directly or reflexly, then the oculist is perfectly justifiable in leaving the errors uncorrected.

In presbyopic cases, however, it is the writer's opinion that in nearly every case the correction for astigmatism should be added to the presbyopia.

I suppose that we all have considerable difficulty with our lady patients in regard to their wearing spectacles. At least I find nine out of ten who beg to have nose glasses, or threaten that they will not wear the spectacles, and probably five out of ten will get the nose glasses any way. This factor, I think, is encouraged by the habit of some of the oculists in acquiescing in the whims and notions of their fair patients, and also by the habit that they have of wearing nose glasses themselves, either because of convenience or looks. I must enter my protest, however, against their use in all cases of astigmatism.

"UREINE."

EXPERIMENTS TO DETERMINE THE TRUTH OF THE *RECENTLY ANNOUNCED DISCOVERY BY MOOR OF* THE TRUE CAUSE OF UREMIA.*

JOHN WEATHERSON, C.E., M.D.
CHICAGO.

When the article by Dr. William Ovid Moor,[1] of Rome, Italy, on "The Discovery of Ureine," appeared and subsequently formed a communication to the Thirteenth International Medical Congress, Paris, 1900, it was pointed out that, if true, it was the most important contribution to urinology, of recent times.

As it offered new fields in the study of the etiology of uremia, dropsy, etc., I began experiments[2] to isolate and to determine its toxic properties.

The method given by Moor for its isolation is substantially as follows: As "ureine" is supposed to be destroyed by a temperature of 80 C., a large quantity of urine is heated at the low temperature of 50 C., until no more evaporation is seen to take place. Silver nitrate is used to precipitate the chlorids; the liquid is then cooled to promote separation of the phosphates, when both chlorids and phosphates are filtered out. The filtrate is again heated at 65 C., until no more evaporation is seen to take place. Alcohol and oxalic acid are used to precipitate the urea which is filtered out. The alcohol is evaporated at 55 C. The sulphates and remaining solids are separated out bv cooling and filtering. The color pigments are removed by treating with mercuric nitrate, neutralizing with sodium carbonate and filtering. The remaining alcohol and water are evaporated at 55 C., when nothing is supposed to remain but "ureine," a pale yellow, oily liquid of a heavy specific gravity and resembling, in aspect, olive-oil.

I have repeated this experiment again and again, following exactly the method given by Moor, and using normal urine in amounts varying from 1000 c.c. to 1700 c.c. for each experiment. I never obtained anything—except in one well-defined case which I will mention later—but a yellow alcoholic liquid which could easily be evaporated at the low temperature of 55 C., and leaving scarcely any residue.

Moor states that this mysterious organic liquid is destroyed by high temperatures, and that, to be obtained pure, an excess of reagents is to be avoided.

To know exactly when every milligram of solid substance of the urine is precipitated, without having added an excess of reagents, is no simple matter. In my later attempts to isolate this organic toxin, I employed the following method: After examining a part of a twenty-four-hour specimen of urine for specific gravity, color, amount of urea, etc., I place from 1000 c.c. to 1500 c.c. of the urine in a large porcelain evaporating dish and evaporate over a low yellow flame at a temperature of not over 50 C. A smaller dish may be used and urine added as the water evaporates. In about thirty-six hours, or as soon as no more vapor is seen to arise from the liquid, the remaining fluid is carefully treated with a saturated solution of silver nitrate until all the chlorids have been precipitated.

To exactly determine this point, I use the following test: On a watch-glass resting on white paper, place a few drops of a saturated solution of neutral potassium chromate. On to this, from time to time, add a drop of the urine and silver nitrate mixture, until a faint pink tinge appears. This pink tinge is due to silver chromate and signifies that all the chlorids have been precipitated and that a trace of excess of silver nitrate now exists. This excess is used up by adding 5 to 10 c.c. of the original concentrated urine set aside for this purpose.

The liquid is now cooled sufficiently for the separation of the phosphates and then filtered, and we wash the filter with distilled water until the liquid comes through colorless. We have now removed all of the chlorids and practically all of the phosphates. The filtrate is now put into a beaker and the water evaporated on a water-bath at a temperature of not over 65 C. To determine this point, Moor uses a large mercury thermometer, placed in the liquid and rapidly withdrawn at 65 C., from time to time. He says a puff of vapor will be seen to arise from the bulb as long as any water remains,

To the remaining liquid add one-half its volume of absolute alcohol. Moor now adds 1 gram of pure powdered oxalic acid for each 100 c.c. of urine used in the experiment. He then carefully adds an alcoholic solution of oxalic acid, stirring and allowing the precipitate to settle after each addition, until all the urea has been precipitated as oxalate of urea. I did not add any specific amount of oxalic acid, since this would vary as the percentage of urea of different urines varied, but I carefully added the oxalic acid and made the following test for excess: On a watch-glass resting on black paper, place a few drops of silver nitrate solution. To this, from time to time, add a drop of the liquid until a white precipitate occurs. This white precipitate is not due to chlorids, since they have been removed, but to silver oxalate ($Ag_2C_2O_4$), and signifies that all the urea has been precipitated, and that a trace of excess of oxalic acid now exists. This excess is used up by adding a few cubic centimeters of the liquid set aside for this purpose. Filter out the oxalate of urea and wash with absolute alcohol. Evaporate at 55 C. The sulphates and remaining solids may largely be removed by cooling and filtering, using alcohol freely to aid filtration. Next, to remove the coloring matter, treat the filtrate carefully with a saturated solution of mercuric nitrate $[Hg(NO_3)_2]$ until no more precipitate occurs.

---

* Read before the Chicago Medical Society, Feb. 21, 1901.

[1] Medical Record, Sept. 1, 1900.

[2] These experiments were performed in the laboratory of Dr. Wm. E. Quine, of which I have charge.

To determine this point I use the following test: On a watch-glass resting on white paper, place a few drops of a strong solution of potassium iodid. To this, from time to time, add a drop of the liquid until an orange or red precipitate appears, which is due to mercuric iodid. This signifies that all the pigment has been precipitated and that a slight excess of mercuric nitrate now exists, which is used up by adding a few cubic centimeters of the filtrate which has been set aside for this purpose. Now neutralize with sodium carbonate, testing with red and blue litmus paper. Filter again and evaporate at 55 C. Pure "ureine" is now supposed to remain.

This method is exactly the method given by Moor, except the tests for excess of reagents, which I have added. This method could be improved upon by using barium chlorid to precipitate the sulphates, instead of trusting to concentrating, cooling, filtering, etc.

I have repeated this experiment, with the refinements here given, many times, and have never obtained anything but clear yellow water and alcohol, which could easily be evaporated at the low temperature of 55 C.

Not succeeding in proving that the "ureine" of Moor is a constituent of urine, I began a series of experiments to prove that it is not. In this I was more successful.

1. Moor, in his publication, assumes that all the water of the urine is evaporated, when he can no longer see vapor arising from the bulb of a large mercury thermometer which is rapidly withdrawn from the liquid when at a temperature of 65 C. It will be remembered that he performed his experiments during the hot summer months. If he had performed them in winter, and as soon as evaporation appeared to cease he had opened his windows to chill the atmosphere of his laboratory, he would have discovered watery vapor arising long after it ceased to be visible in a warmer atmosphere. It is well known that the watery vapor of expired air of man and animals, which can not be seen in summer, is plainly visible on a cold wintry day. Again, he fails to consider the considerable amount of water which would be retained in thick concentrated urine as water of crystallization and which is very hard to drive off at the low temperature of 55 to 65 C.

Water is no doubt present long after Moor assumes it to be absent. But I have been able to evaporate 1600 c.c. of urine on a water-bath, at the low temperature of 55 C., to the consistency of a thick syrupy mush, amounting in volume to not more than two ounces, and driving off nearly all the liquid except what was retained as water of crystallization. The evaporation required several days, but the temperature was never near the point required to decompose "ureine" (80 C.) if any had been present.

To prove that the remaining fluid is water of crystallization and not an oily liquid "ureine," the following experiment is conclusive: Pour the thick syrupy mass mentioned above, from the beaker on the water-bath into a large flat dish. On cooling, the liquid crystallizes into a solid mass, which soon becomes quite hard and dry. Fifty c.c.—nearly two ounces—of liquid "ureine," which is stated to exist in normal twenty-four-hour urine, should be plainly visible if present. The volume of the entire mass which I obtained by evaporation amounted to less than two ounces.

Now, since by supposition, "ureine" is an oily liquid, which remains intact and constant, at temperatures below 75 to 80 C., and since normal urine can—except some water of crystallization—be evaporated to dryness at the low temperature of 55 C., the conclusion is irresistible that there is no such substance as liquid "ureine."

2. It is well known that the total solids of average twenty-four-hour urine amount to from 60 to 70 grams. This includes both organic and inorganic substances. Also, it is known that, of the above amount, urea constitutes about one-half or from 30 to 35 grams. Moor states that the specific gravity of "ureine" is 1270, or it is as heavy as glycerin. That is, "ureine" is nearly as heavy as urea, whose specific gravity is 1323. Yet farther along in his article he states that "ureine" exists in amount equal to twice that of urea. That scientific investigators all over the world should fail to discover an organic substance in the urine amounting to 50 to 60 c.c., which would weigh 65 to 70 grams, or as great as the total known solids, is highly improbable.

3. Moor asserts that he examined the urine of a diabetic woman and found 6 per cent. of "ureine," 2.1 per cent. of urea, and that the specific gravity was 1025 and that the total urine passed in twenty-four hours was 1250 c.c. This statement alone would condemn the article before any scientific body in existence. Let us consider it in detail.

I carefully made up two solutions as follows: Solution No. 1 consisted of distilled water, in which was dissolved 2.1 per cent. of pure urea crystals, which equalled the amount found in this diabetic urine. Solution No. 2 contained 0.9 per cent. of sodium chlorid, the normal amount for 1250 c.c. of urine. By the Mohr-Westphal balance I found: Specific gravity of Solution No. 1 = 1005.5; of solution No. 2 = 1006.5 The formula for the specific gravity of mixtures gives slightly higher values.

To find what the specific gravity of a solution containing water and 6 per cent. of a liquid "ureine," whose specific gravity is 1270, would be, I make use of the following well-known formula:

$$X = (V^1 \text{ x } S^1) + (V^2 \text{ x } S^2) \div (V^1 + V^2)$$

where V^1 and V^2 represent the volume of the liquids used, and S^1 and S^2 their respective specific gravities. Substituting 94 per cent. water with a specific gravity of 1000, and 6 per cent. "ureine" with a specific gravity of 1270 we have:

$$X = (V^1 \text{ x } S^1) + (V^2 \text{ x } S^2) \div (94 + 6) = 1016,$$

the specific gravity due to "ureine" alone. This formula, while the one commonly used, is not absolutely correct when tested by experiment, because the actual volume of a mixture does not always equal the sum, in figures, of the separate volumes used. This is due to what is known in physics as "interpenetration" resulting from the porosity of substances, which exists even in liquids. But it is sufficiently correct for our purpose. We now have: Specific gravity due to 2.1 per cent. urea = 1005.5; due to 0.9 per cent. Na Cl = 1006.5; due to 6 per cent. "ureine" = 1016; total for only these *three* substances = 1028.

I have not considered the specific gravity due to sulphates, phosphates, pigments, sugar, etc., which without "ureine" would bring the specific gravity to about 1025, as Moor found it. But if 6 per cent. of a heavy liquid had been present, the specific gravity would be about 1040 instead of 1025. This experimental and mathematical check on the specific gravities is the most conclusive proof we have that the whole proposition is without foundation.

But while there is no such a single toxic substance as "ureine," it is well known that normal urine is toxic. That it is not due to urea or uric acid has been proved many times. Bouchard states that there are at least seven different toxic agents in normal urine. None of these have been completely isolated. Their sum-total, including pigment, however, amounts to but a few grams.

It has been found by experiment that an aqueous extract of the urine, when injected into rabbits, causes contraction of the pupils and convulsions, but no coma: while an alcoholic extract of the urine causes deep coma, but no convulsions nor contraction of the pupils.

Since we have shown that Moor probably did not drive off all the water of the urine by evaporating at low temperatures, and since he used alcohol freely in all his experiments, and since the rabbits into which he injected his supposed "ureine" died with both coma and convulsions, the irresistible inference is that Moor's "ureine" is a mixture of aqueous and alcoholic extracts of the several toxic ingredients of normal urine. His 50 to 60 c.c. of "ureine" probably consisted of water and alcohol, in which were dissolved a little pigment with the several organic toxins, and some compound of oxalic acid.

It will be remembered that in precipitating the urea, Moor uses an alcoholic solution of oxalic acid, after he uses the powdered form, and which he makes, by dissolving 3 grams of oxalic acid in 10 cubic centimeters of hot alcohol. I made up such a solution, but used it only a few times and then only in small quantities. From Watt's "Dictionary of Chemistry," I learn that if alcohol and oxalic acid be heated together at a high temperature, one part of oxalic acid will combine with nearly the same amount of alcohol to form di-ethyl-ether, or oxalic ether, which is a colorless oil whose specific gravity is 1079. Whether true oxalic ether, or some closely related compound was formed in this case, I do not know, but at any rate when I evaporated the excess of alcohol from the solution I had made up, I found a liquid which left a permanent oil stain on paper, similar to that produced by olive-oil, but not so marked. Oxalic acid dissolved in cold alcohol did not leave these oil spots.

It is interesting to note that at the close of the second attempt at isolation which I performed by Moor's method, I found about 4 c.c. of a liquid which resembled "ureine." But this was the only time, and it was in this experiment that I used the extra quantity of the alcoholic solution of oxalic acid mentioned above. This liquid looked like olive-oil and left a permanent oil stain on paper. It did not have the odor of urine, but it was a pale-yellow color and had the aromatic odor of alcohol. This liquid I believe to be, principally, some oil closely related to oxalic ether. At any rate, a drop of it, with a drop of silver nitrate solution, gave the white precipitate of silver oxalate. It is the presence of some oxalic compound, no doubt, that leads Moor to ascribe de-oxidizing powers to "ureine," oxalic acid being a great reducing agent and readily decolorizing solutions of the permanganates. The presence of this substance, no doubt, helped to mislead Moor. Again, he states that "ureine" belongs to the alcohol group of the aromatic series, and that it splits up at a temperature of about 80 C. There is undoubtedly alcohol there, because he put it there, and his statement that "ureine" splits up at 80 C. is no doubt due to the fact that the boiling point of alcohol is exactly 78.39 C. Again, he states that the characteristic odor of urine is due to "ureine." In my own experiments I found that the odor disappeared when the pigment was removed, due probably to some substance precipitated at the same time. Considerable pigment remaining, however, would give an odor, and also add toxic properties, since the researches of Ritter, Bouchard and Lenoir show that when normal urine is deprived of coloring matter its toxic powers are reduced one-third.

The subject of toxins of the urine is very interesting and highly important, but I can not see that Moor has added anything to our present knowledge of urinology.

DISCUSSION.

Dr. John A. Wesener stated that after going over Moor's article very carefully he finds that there is no chemistry whatever in his paper. In fact, it is an article made up simply of words and facts relegated to the background. He was very glad to see that the essayist has shown most emphatically the absurdity of Moor's new compound—ureine. He said that there are a few points to be considered in this article, and when these are thoroughly brought out the so-called "wonderful compound," "ureine," will immediately fade from sight. Moor says that the specific gravity of ureine is 1.27, and the amount of ureine found in the urine under normal conditions is nearly twice that of urea; therefore, assuming that we have a 6 per cent. solution of ureine, the specific gravity of that solution alone would be 1.015. It is known that when the last two figures of the specific gravity are multiplied by 2.33, and then these figures computed to the total amount of urine passed in twenty-four hours, we get approximately the total solids. Furthermore, we find that if a given quantity of urine is evaporated to dryness, and then weighed, the total solids would correspond very well with the above principle. Moor says that ureine decomposes very readily at low temperature, 80 degrees splitting it into new compounds. The speaker suggests that evaporation under those conditions should have been done in a vacuum. Moor's method of removing salts and coloring matter from the urine is a very poor and inaccurate one. Furthermore, Moor says that potassium ferrocyanid and ferric chlorid, when treated with ureine, turn blue. The speaker has always been taught that potassium ferrocyanid and ferric chlorid, when mixed, always gave Prussian blue. Moor probably means to use the red prussiate of iron instead of yellow, but even a mixture of red prussiate of iron and ferric chlorid will turn blue when treated with organic substances. For example, tincture of guaiac will change this solution to a blue color; therefore the speaker would not be surprised that the coloring matter in the urine should, when treated with these two salts, give a blue reaction.

Moor's formula of oxalate of urea can not be recognized by chemists as belonging to any known compound. How he estimated urine is beyond the speaker's comprehension. If he simply weighed the solution, then what he weighed was a most impure product. He not only weighed a certain amount of coloring matter, but also salts, which he failed to remove by his process. The statement is also made that the urine is a liquid composed of water and inorganic solids. It is known that the urine contains between 3.5 and 4 per cent. of solid matter, of which 1.75 per cent. is inorganic and 2.25 per cent. organic. Moor tells us that ureine belongs to the alcohol aromatic group, and when heated it splits into oxy-acids, etc.

Probably the most emphatic and absurd statement made by the author is that "the fermentation of urea is caused by ureine, and that bacteria alone could not bring about this change, and without ureine all organic matter would become converted into urea, which would remain in Nature without any use, and thus within a limited period of time all vegetable and animal, as well as human, life would cease." It has been shown most emphatically that pure solutions of urea are changed to ammonium carbonate by a great variety of bacteria. In order to have the fermentation brisk and rapid a certain amount of nourishment in the form of peptones, ammonia salts, glycocol, etc., is necessary. Furthermore, if a decomposed urine is precipitated with alcohol, this precipitate dried and powdered and an aqueous extract made of it, and then added to a solution of pure urea, fermentation takes place quickly, ammonium carbonate being the result.

In this particular instance the enzymes of the bacteria change the urea into ammonium carbonate.

The speaker does not think any members of the profession need have any fear that without ureine urea would remain as an end product of nitrogenous metabolism. The bacteria will very readily convert it into ammonium carbonate in spite of the fact that it is, in the opinion of Moor, a most stable compound. In fact, the air itself would in time change urea to ammonium carbonate. Bacteria not only change ammonia to nitrites and nitrates, but we have a reversible action where the nitrates are changed back to ammonia. These salts are much more stable than urea, being inorganic instead of organic.

Dr. William A. Evans said that the essayist had answered the statements of Dr. Moor so thoroughly that neither the original paper nor the refutation thereof would require any attention. From the statement, in Dr. Weatherson's paper, that urea was non-toxic, he gave some observations drawn from a paper written by Dr. Herter for the Welch "Festschrift." Since 1865, when Frerichs popularized the belief that uremia was not due to urea, there has been a growing disposition to regard this substance as almost, if not entirely, harmless. The work of Dr. Herter demonstrates that while urea is not a very actively toxic agent, and while it is readily eliminated by any one of several routes, at the same time it has some toxic action, and is responsible for some part of the symptoms known under the symptom-complex of uremia. He determined that the dog's kidneys secrete twenty times the normal quantity of urea; that ten grams of dog's kidney can secrete 1.57 grams of urea in one hour; that the kidney of the Batrachian was less efficient, and that the mammalian kidney rose in efficiency as it advanced in the scale of life. . .

It has been determined by other authorities as well as by Herter that when a large amount of urea is thrown into the circulation the amount recovered from the urine is considerably less than the amount injected. This difference represents the urea which was stored in the liver, the brain, the muscle and other structures, as well as the urea which is eliminated by the gastrointestinal tract, and the sweat glands. In 1898 Drs. Hoelscher and Wesener showed that in some cases of *chronic nephritis and* acute articular rheumatism the proportion of urea in the sweat amounted to .3 of 1 per cent. Herter and Wakeman have shown that whereas there is habitually some little elimination of urea by the gastro-intestinal tract when the percentage of urea in the blood amounts to .2 of 1 per cent., there is a great increase in gastro-intestinal elimination, accompanied by congestion of the mucosa and submucosa, dropsical accumulation in the epithelium, together with considerable desquamation thereof; that if the proportion of urea amounts to considerably above .2 of 1 per cent., the gastro-intestinal epithelium fails to eliminate urea further. In the experiments of Herter if an urea solution stronger than 4 per cent. was injected, there followed hematuria, albuminuria, decrease in the quantity of urine, and finally total suppression; that the decrease in the waters of the urine preceded the decrease in urea. It was demonstrated that in the case of dogs and monkeys convulsions, bearing a close resemblance to uremic convulsions, came on when the blood contained .3 of 1 per cent. urea, and death invariably followed when the blood contents of urea had amounted to .6 of 1 per cent. The urea in normal human blood amounts to .05 of 1 per cent. In pathologic conditions accompanied by a normal kidney epithelium, there is but little danger of accumulation of urea in the blood or in the tissues, regardless of the amount that is manufactured or absorbed. If, however, there is destruction of kidney epithelium as the result of causes acting at present, or as the result of causes previously acting, for example chronic nephritis, there is liable to be an increase in the blood-current of urea. Bradford offers a study of three cases of anuria, in which the blood percentages were .277, .324 and .44, respectively. Herter, in a study of fourteen cases of lobar pneumonia, found increases of urea ranging from an increase of 64 per cent. in one case to an increase amounting to 1200 per cent. in another. In every case of chronic nephritis examined the urea in the blood was found to be increased. He divided hs cases into three groups: The first, in which the percentage of urea in the blood was .1 of 1 per cent. or less: the second, in which it varied between .1 of 1 per cent. and .3 of 1 per cent.; the third, in which it was .3 of 1 per cent or over. The symptoms of these cases were those ordinarily recognized as the symptoms of uremia. The mode of death of the dog that died after taking unusually large injections of urea was the same as that in the condition known as uremia. It is difficult to determine whether the symptoms of uremia are due to urea or to other urinary ingredients, but it is to be remembered that in the case of the dog no urinary ingredient was injected except urea. Dr. Herter makes the statement that creatin, uric acid and other members of the xanthin group could not be the pathogenic agents in these cases. He called attention to a point that clinically has been observed most frequently by all of us, namely, that there is great difficulty in determining whether the symptoms of uremia were due to urea by quantitative examination of the urea in the urine. It would be necessary to examine the urine quantitatively for urea day by day for a considerable time, and to know with certainty how much urea was absorbed from the food, and how much was excreted by the gastro-intestinal tract and by the perspiration. As these considerations are altogether impossible, the quantitative determination of the urea in the urine gives us an altogether incomplete idea as to the amount of urea in the blood, and it is the urea in the blood and in the tissues that is responsible for any effects that urea might have.

Dr. Weatherson, in closing the discussion, stated that Professor Haines, of Rush Medical College, had been working on the same subject and had conducted a series of experiments which corroborated his own conclusions.

ANASTOMOSIS OF THE URETERS WITH THE INTESTINE.

A HISTORICAL AND EXPERIMENTAL RESEARCH.[*]

REUBEN PETERSON, M.D.

Professor of Gynecology Post-Graduate Medical School; Assistant Clinical Professor of Gynecology, Rush Medical College; President of the Chicago Gynecological Society.

CHICAGO.

(Continued from p. 635.)

AUTHOR'S EXPERIMENTAL WORK.

The following experiments, begun nearly eighteen months ago, have been performed at the Post-Graduate Hospital and Experimental Laboratory and in the Physiological Laboratory of the Chicago University. The bacteriologic and microscopic work has been conducted entirely by my friend, Dr. F. Robert Zeit, professor of pathology at the Post-Graduate Medical School, and I gratefully acknowledge my indebtedness to him for the thorough manner in which he has performed a most ardous task.

Dogs were used for all the experiments, and chloroform was always employed for anesthesia. As the work was to include the intestinal tract, various methods of emptying the animal's bowels preparatory to the operation were tried. The administration of cathartics the day previous to the operation was a dismal failure, as a diarrhea always ensued, and even after the exercise of the greatest care liquid feces escaped through the incised gut wall. As the operation was to be upon the lower bowel, attempts were made to empty it by large rectal injections, but this method failed until it was accidentally discovered that it could be most satisfactorily accomplished on the *anesthetized* animal. The rectum and descending colon can be so thoroughly cleansed by this method as to enable one to entirely dispense with bowel clamps. This has been dwelt on at some length because fecal contamination was responsible for many deaths in the first series of cases.

The most rigid asepsis was employed in every operation. Silk ligatures and sutures were used. The abdominal wound was closed by interrupted through-and-through sutures. In the large majority of cases it was found impossible to keep the abdominal wound aseptic, and suppuration ensued, but in only a few cases was this followed by any serious results.

For the first twenty-four hours the animal was given nothing but water, and the diet was limited to milk for the next two days. After the first few days the surviving dogs were given ordinary food. After the first week the animals were allowed to run with their fellows, and no especial care was given them except to note carefully any change in their condition.

---

[*] Read before the American Gynecological Society, Washington, D. C., May 1, 1900.

In giving a detailed account of the experiments no attempt will be made to gloss over faults in technique, which, in the light of subsequent operations, were apparently inexcusable. When one form of operation failed another was tried, only to find later on that the change had been made in the wrong direction. The loss of so many animals necessitated a vast amount of work, since the main object of the experiments was to determine the ultimate effect upon the animal of uniting the urinary and digestive tracts.

Three series of experiments were conducted:

1. Bilateral uretero-intestinal anastomosis.
2. Lateral uretero-intestinal anastomosis.
3. Uretero-trigono-intestinal anastomosis.

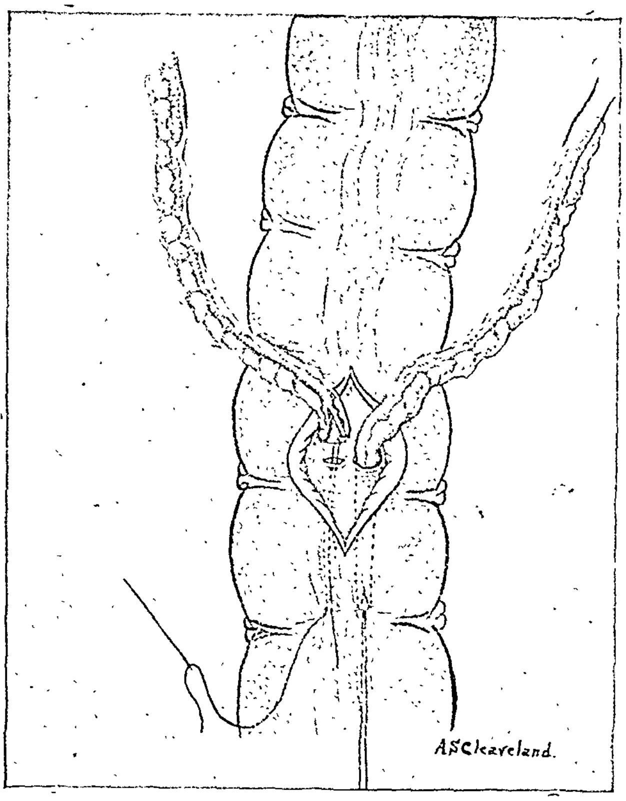

Fig. 12.—*Uretero-intestinal Anastomosis.* Serosa and muscularis incised. Ureter split and drawn through small incisions in mucosa by sutures passed through intestinal wall 1½ inches below lowest point of incision.

1. BILATERAL URETERO-INTESTINAL ANASTOMOSIS.

Both ureters were implanted simultaneously in the rectum in twenty-eight dogs, with five recoveries and twenty-three deaths. In five dogs an operation similar to that described by Fowler was employed. The serous and muscular bowel coats were incised for a number of inches and a mucous flap formed upon which the ureters were implanted and sunk in the bowel. All these dogs died in from two to five days, of peritonitis and escape of urine into the peritoneal cavity from a sloughing of bowel-flap and giving away of the stitches.

In twenty-three dogs the following plan of operation was adopted with various modifications of technique: An incision was made into the bowel-wall through the serous and muscular coats. The ureters were implanted in the rectum through small incisions made in the mucosa and either their outer coats or peritoneal coverings. The serous and muscular flap was then drawn over the ureters and secured by interrupted Lembert sutures. In some cases the ureters were passed through one and in other cases two incisions in the mucosa. Of these twenty-three cases, five recovered and eighteen died.

Causes of Death. In most of the cases death ensued from general peritonitis, usually accompanied by escape of urine into the peritoneal cavity. This escape of urine in most instances arose from a slough at the site of anastomosis. In a few cases there was a well-marked slough of one or both ureters. In three cases one or both ureters pulled out of the incision and opened into the peritoneal cavity. In three instances uremic coma, caused by acute nephritis, was responsible for death.

The ureters were, as a rule, dilated in the dogs dying shortly after the operation, although the uretero-rectal orifices were patent to a stream of water injected into the pelves of the kidneys. In the majority of instances the pelves of the kidneys were dilated and filled either with urine or purulent fluid. The split kidneys showed evidences of acute nephritis, being enlarged, soft, and intensely congested.

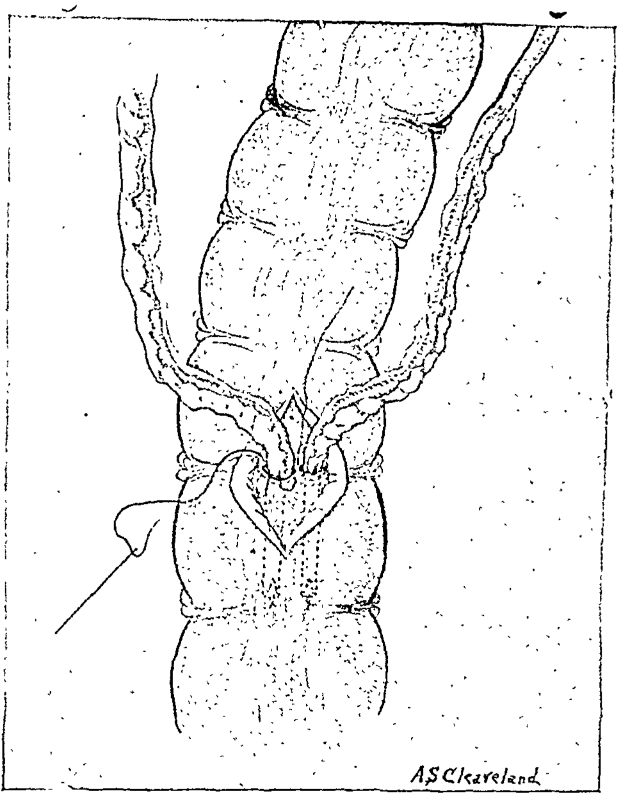

Fig. 13.—Both ureters held in place by tying of lower sutures, showing method of closing mucosa about ureter by passing sutures through mucosa and peritoneal covering of ureter.

In a few instances bacteriologic and microscopic examinations were made, although this was considered unnecessary in the other fatal cases, since the causes of death were only too apparent.

All the dogs in this series were operated upon without a proper cleansing of the rectum, and fecal extravasation through the incision made in the mucosa was extremely common. This led, in quite a number of cases, to infection of the flap and sloughing of the sutures.

At first the incisions in the bowel were made unnecessarily long and too much raw surface was exposed to the dangers of infection. The statistics improved immediately the incision was shortened.

In the first eight cases the ureter was located near the bladder and then dissected upward for a number of inches by the finger. This was a mistake, since it interfered with the ureteral blood-supply and did not leave any peritoneum on the ureteral coat.

Any failure to close securely the mucosal openings through which the ureters passed led to fecal extravasation; if they were closed too *tightly stricture* of the ureter and hydronephrosis ensued. It was soon found that the dog's ureter was extremely delicate and would not stand sutures passed through any of its coats without great danger of resulting stricture. This was obviated by passing the sutures through its fatty and peritoneal envelopes.

The chances of pulling out the ureter were found to be lessened by securely fastening the two ends of the ligature, by *means of which* the ureter was drawn through the incision in the mucosa. The greatest care was found necessary in order not to constrict the ureters by the serous sutures. A number of deaths from hydroureter and hydronephrosis were explainable from the failure to observe these precautions.

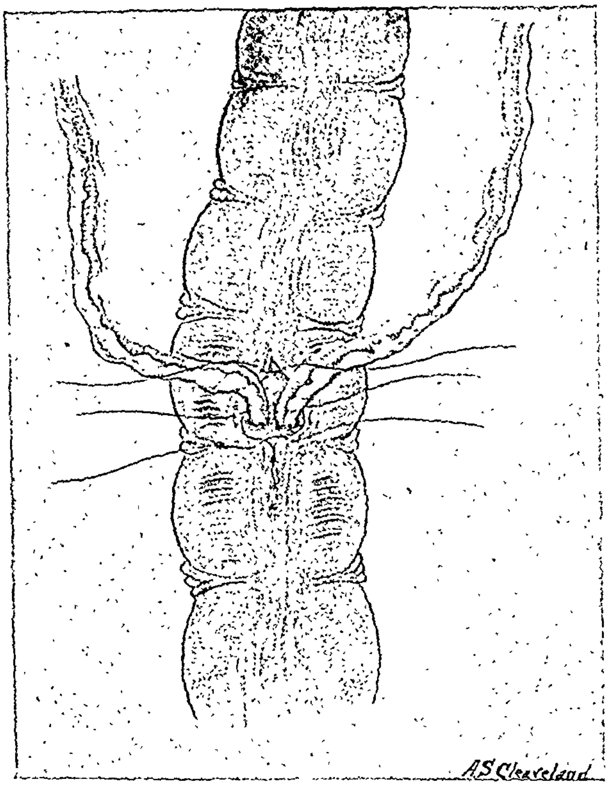

Fig. 14.—Ureters secured in position, serosa and muscularis being closed about ureters by a row of interrupted Lembert sutures.

Naturally the greatest interest centers in the five dogs that recovered from the operation, and, therefore, these experiments are given in detail.

Experiment 22. Dog I. Large black spaniel. Operation February 26, 1899. An abdominal incision was made, three inches in length, as low down as possible, and two inches to the left of the penis. The ureters were lifted up from the *bottom* of the pelvis and loosened for three inches by the scissors, care being taken to preserve a portion of the peritoneal covering. Each ureter was severed *about one and one-half* inches from the bladder and wrapped in sponges. A *one-half* inch incision was now made through the serous and muscular coats of the rectum and the two flaps separated outward by blunt dissection. A suture armed at each end with a needle was passed *through the end* of each ureter after the latter had been slit upward *one-third of an inch. Two small* one-fourth-inch incisions were now made at the lower and *outer* surfaces of the exposed mucosa. Through these openings the needles were passed and brought out of the bowel *one inch* below the point of entrance. The ligatures were now tightened and the ureters drawn downward through the incisions in the mucosa. The mucosal apertures were closed about the ureter by fine silk ligatures passed through the mucosa and outer coats of the ureter. The serosa was now closed by interrupted Lembert sutures. (See Figs. 12 to 14.)

The dog made an excellent recovery, had *good control over* his urine, which he voided, mixed with *feces, about every four* hours. One month after the operation he did not seem so well, and there was a whitish discharge from the penis, with straining and considerable pain. These symptoms increased in severity, and the dog was killed forty days after the operation.

Pathologist's Report. Post-mortem, April 26, 1899, forty days after operation. Liver, spleen, heart and lungs normal. In the rectum was a *papilla*, on the sides of *which* were two ureteral openings, both of which were *patent*. Capsules of both kidneys slightly adherent. Left kidney showed a few *yellow*ish purulent foci on cortex, with yellowish rays from pelvis to cortex. Right kidney was slightly granular. The bladder, small and contracted, contained whitish purulent fluid.

Bacteriology. Substance and pelves of kidneys free from bacteria. Bladder contained short bacilli, similar to diphtheria or streptococci, no bacteria in heart, liver or spleen.

Histology. Proliferation of interstitial connective tissue forming dense rays from papillæ to *cortex* with *retraction on* surface *of* cortex. Many dilated desquamated *tubules.* Increased connective tissue around glomeruli. Some cloudy swelling in remaining epithelium of tubules.

Experiment 25. Dog II. Large hound. Operation March 11, 1899. Technique same as in Experiment 22. This dog hardly had a sick day after the operation. April 20, was killed while fighting with a bulldog.

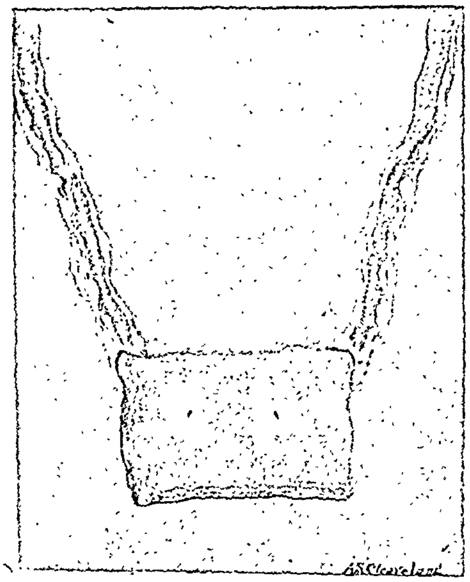

Fig. 15.—Author's modification of Maydi's operation (uretero-trigono-intestinal *anastomosis*). *Rectangular vesical flap* containing ureteral orifices. Ureters have been dissected free from their peritoneal coverings in order to be more plainly seen.

Pathologist's Report. Autopsy April 20, 1899, forty days after the anastomosis *of both ureters with the* colon, twelve inches from the anus. Pyemia; secondary infection; endocarditis. Ureters were patent and emptied into two small papillæ *in rectum* size of small peas and one-eighth of an inch apart. The intestine was studded with smaller papillæ. Left kidney: *purulent foci* in cortex. Pelvis contained purulent fluid. *Pyelonephrosis ascendens*; hydro-ureter. Right kidney apparently *normal, no* dilatation of ureter, but pyelitis present and a few purulent *foci* in *cortex*; *capsule* strips easily. Bladder was contracted and contained *purulent fluid.* Spleen soft, liver contains a few purulent foci. Heart and lungs normal except fibrinous thrombi in both ventricles extending into large vessels.

Bacteriology. Left kidney cortex, coli bacilli. Right kidney cortex, coli. Bladder: *large coli* and a few small diphtheroid bacilli and streptococci. Liver: *many coli.* Spleen: no bacteria.

Histopathology. Left kidney: hyperplasia of *interstitial* connective tissue. Walls of small blood-vessels thickened. Fatty and cloudy epithelial cells lining tubules here and there filled with granular detritus. Right kidney: interstitial infiltration *from pelvis to cortex* in narrow rays surrounded by tubules showing cloudy *swelling* and fatty degeneration of lining epithelium of convoluted tubules in places necrotic.

Experiment 18. Dog III. Small brown dog; operation February 11, 1899. Same technique as in previous experiment, except the silk stitches used to close mucosal opening took in outer coat of ureter instead of merely peritoneal and fatty coverings. Was never in as good health as dogs I and II. Gradual loss of flesh. Died May 6, 1899. Post-mortem same day.

Pathologist's Report. Died from pyemia and secondary infection eighty-four days after operation. Implantation of both ureters in rectum. Pyelonephrosis and pyoureter on right side; ureter not patent. Pyelonephritis left side; ureter patent. Spleen and liver soft, bladder contracted and filled with purulent fluid; heart contains organized thrombi.

Bacteriology. Both kidneys contain coli; bladder contains staphylococci and diplococci; unfortunately the blocks were lost, and no microscopic examinations were made of the kidneys.

Experiment 27. Dog IV. Large dog; operation April 17, 1899. Same technique as in other experiments; died May 26; attendant failed to notify pathologist until the dog was in bad condition.

Pathologist's Report. Death from pyemia and endocarditis after thirty-nine days. Implantation of both ureters in rectum; operative results good. Right kidney: pyelonephritis and pyeloureter. Left ureter normal. Both ureters patent. Bladder contracted, containing purulent fluid; endocarditis; spleen large and soft; purulent foci on surface of liver. No bacteriologic or microscopic examinations made.

Experiment 19. Dog V. Medium-sized gray bitch; operation February 15, 1899. Same technique as in other operations, except both ureters passed through one incision in mucosa and secured by sutures through mucosa and peritoneal coverings. Dog made a good recovery. Lost some flesh for first month, then remained in perfect health until killed, twelve months later.

Pathologist's Report. (Dox X, pathologic report.) Both ureters in rectum; killed after thirteen months and ten days; recovery from pyelonephritis with contracted kidney. Cultures taken while alive, under chloroform; liver and spleen normal; bladder, contracted to size of hickory nut; kidneys, capsules opaque and congested, slightly adherent, surface nodular and contracted; pelvis, opaque and thickened; radiating yellow lines from pelvis to surface of kidney. Pelvis of left kidney contains a mass of grayish concretions. Ureters: bilateral dilatation; patent. Smears and cultures from both kidneys. Spleen, liver and left ventricle were negative.

Histopathology. There is present an interstitial pyelonephritis; abscesses emptied by absorption of pus and evacuation into the pelvis of the kidney. The newly formed connective tissue has matured and contracted. Microscopically the elevated portions consist of fairly normal parenchyma. The retractions consist of new formed and matured connective tissue with atrophic glomeruli and thickened capsules in its neighborhood. The blood vessels have thickened walls. The tubules are dilated and desquamated.

The operative results in the five dogs recovering from the operation may be termed fairly good. In only one case was the ureter thought not to be patent. In all the other instances the uterers were patent and opened at the sides of small papillæ in the rectum, the openings looking not unlike the normal vesico-ureteral orifices. (See Fig. 20.) In four of the cases, however, the ureters were dilated, showing that the uretero-rectal openings had contracted. In one case pyo-ureter, and in another hydro-ureter, was noted.

Each of the five cases showed the gross lesions of an ascending renal infection confirmed in nearly every case by bacteriologic and microscopic examinations. The extent and virulence of the infection varied. In three cases it was so severe as to lead to secondary infection, endocarditis and pyemia. In one case the dog when killed was recovering from a pyelonephritis, and in the most interesting animal of the lot a complete recovery took place after the pyelonephritis, with resulting contracted kidneys. *In both these cases the cortex and* pelves of the kidneys were free from bacteria, showing that the animals had become immune to the colon bacilli. In the other cases, however, the micro-organisms were abundant and showed the presence of an active infective process.

2. LATERAL URETERO-INTESTINAL ANASTOMOSIS.

Sixteen dogs operated upon, with three recoveries. Twelve died of general peritonitis due to leakage through the stitch-holes; one died of hemorrhage.

The object of these operations was to unite the ureters to the bowel by a lateral anastomosis, so that dilatation of the ureters and ascending infection could be avoided. The task presented many technical difficulties because of the small size of the ureters even in the largest dogs, and the tendency to leakage when the through-and-through stitch was employed. The ureters were cut away close to the bladder and dissected upward for two and a half inches, together with a fold of peritoneum. A slit one-half inch in length was then made in the ureteral wall one-half inch above cut end, and the same length incision made in the serous and muscular intestinal layers. The anastomosis was made by a continuous right-angled stitch passing through the ureteral wall and the peritoneal and muscular layers of the intestine. Before the suture was drawn tight the bowel mucosa was cut the entire length of the incision. In the first two dogs recovering the mucosa was simply incised. In the last animal a portion of the mucosa was removed. The operation was completed by tying the severed ureters.

Experiment 32. Dog VI. (Dog V Pathological Reports.) Great Dane pup. Operation September 20, 1899. Lateral anastomosis of left ureter with rectum, according to method described above; mucosa simply incised.

Pathologist's Report. Dog lived sixty days. Right kidney capsule adherent, ureter dilated; nodule size of pea where ureter entered rectum. Heart: fibrinous organized clot in right auricle and ventricle. Liver covered with numerous yellowish areas.

Bacteriology. Right kidney, coli; Liver, coli.

Histopathology. Same as in dog I. Death from pyelonephritis with pyemia.

Experiment 33. Dog VII. (Dog VIII. Pathological Reports.) Yellow bitch. Operation September 22, 1899. Technique same as in Dog VI. Lost flesh, and died December 18, 1899. Autopsy, same day.

Pathologist's Report. Died eighty-seven days after operation. Right kidney, capsule adherent; pyelonephritis. Right ureter contains pus. Liver hyperemic. Heart, yellow fibrinous thrombi in left auricle and ventricle. Septic endocarditis. Death due to pyemia and endocarditis.

Bacteriology. Left heart, liver, and right kidney show coli.

Histopathology. Right kidney atrophic and granular, much interstitial hyperplasia, with contraction. Some small-cell infiltration, dilated desquamated tubules and atrophic glomeruli, with thickened capsules.

Experiment 50. Dog VIII. (Dog IX. Pathological Reports.) Operation November 18, 1899. Same technique as in other two dogs, except line of sutures protected by peritoneal flaps.

Pathologist's Report. Death due to toxemia and pyelonephritis. Ureter patent and not dilated. Left kidney very much enlarged. Pelvis dilated and filled with pus.

Bacteriologic and microscopic examinations showed findings already described in cases of pyelonephritis.

This last case has been included among recoveries, since death was due to infection and not to failure of technique. The first two cases died in sixty and eighty-seven days respectively of pyleonephritis, pyemia, and septic endocarditis. They can hardly be considered fair tests of the operation of lateral anastomosis, since the slit in the mucosa partially closed, and may have produced the dilatation of the ureter. The last case, however, was perfect from an operative standpoint, there being absolutely no obstruction to the flow of urine or dilatation of the ureter. Yet death resulted in ten days from pyelonephritis and pyemia.

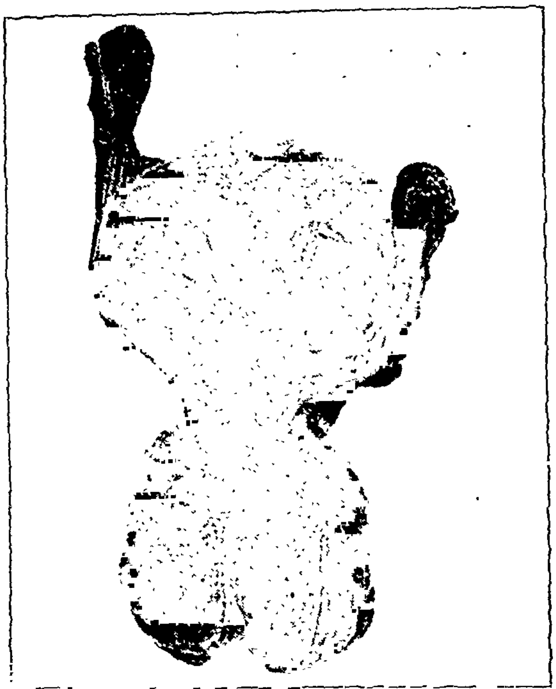
(To be continued.)

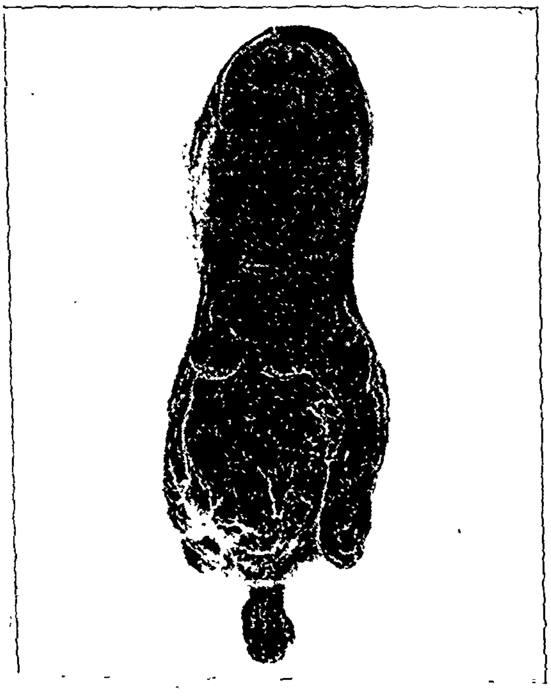
Clinical Report.

ABDOMINAL HYSTERECTOMY FOR MULTIPLE FIBROMA WITH A FIVE-MONTH GRAVID UTERUS.

GEORGE R. GREEN, M.D.
MUNCIE, IND.

On July 13, 1900, I was asked to see a married woman 28 years of age. She was confined to bed with a temperature of 101 F., irregularly enlarged abdomen, nodular in form, but with some elasticity, circumscribed peritonitis on the left side with pain and great tenderness, so much tenderness in fact as to make abdominal palpation almost valueless. Ten years ago the patient complained of a lump in her side; it remained stationary, however, or increased very little in size. Eighteen months before my visit she had married, and thirteen months later gave evidence of pregnancy, i. e., suppression of menses, morning sickness, etc. At this time this tumor—so long known to exist—began to grow rapidly and became very painful, so much so that she was finally forced to keep her bed and accept the daily use of anodynes to secure rest.





At the time of my visit she looked ill, her weight was not over 90 pounds; she was pale and weak, with rapid pulse, loss of appetite, abdominal distension and constant pain. I advised an exploration, so that, if possible, the growth might be removed, or at least its exact nature determined, explaining to the patient that the fact of a possible pregnancy would not necessarily prevent us from removing a fibroma if found advisable, her general condition being such that she would otherwise hardly live to the end of gestation.

On the morning of July 17, with the usual precautions, I opened the abdomen by a median incision and, separating some extensive adhesions on the left side and enlarging the abdominal opening, I succeeded in bringing a fibroid as large as my two fists into the opening; this was followed by another as large, and lastly, a gravid uterus studded with many other like growths of various sizes and scattered over the entire uterine wall, some subserous, others deeper. For the first time I held a living gravid uterus in my hands, and I was very forcibly impressed by the very great thinness of its walls. and if the normal uterus at term is as thin as that, I only wonder why more of them do not rupture during the violent contractions necessary in labor.

Hastily consulting with my assistants, we thought the only feasible thing to do was to remove the entire mass, uterus included. Ligating the uterine arteries, I cobble-stitched through the cervix to prevent the possibility of vaginal infection, and cut away the entire mass, cutting through the cervix close to the stitches; but little blood was lost, though the shock was profound, and after irrigating the abdominal cavity with hot salt solution, I allowed as much normal salt solution as I could to remain, and closed without drainage. Twenty-four hours later the pulse-rate was 140 and I gave, by hypodermoclysis. one quart of normal salt solution into the tissues underneath the mammary gland and requested the nurse and attending physician to repeat in eight hours and again in sixteen.

From this time the patient gradually improved and on removing the dressings on the tenth day the abdominal wound was healed. She was out of bed in four weeks and is now well. So far none of the nervous manifestations of the artificial menopause has developed.

The specimen was presented to the pathological section of the Indiana State Medical Society.

Psychoses Following Operations.—At the meeting of the Edinburgh Obstetrical Society, February 13, Dr. J. Haliday Croom (*The Lancet*, March 2) read a paper on psychoses following peri-abdominal operations, and reported cases, incidentally making some remarks on operations undertaken on insane women for a cure of the mental disease. Dr. Croom considers that under no circumstances ought any insane woman to be operated on unless there is some distinct condition that is compromising life. Removal of ovaries and other operations with a view to influencing better conditions of insanity and hysteria were very unpromising. After degenerative processes have taken place in the brain, he considers it absolutely useless to look for any mental cure by any form of operative procedure. As regards the insanity from operation, his own records show five cases in a thousand abdominal sections. In looking for the causes of these mental disturbances after operation, the first factor was the hereditary one, and the second possibility was sepsis; loss of blood, defective action of the kidney, etc., also had their influence in producing mental symptoms. In removing the ovaries the climacteric was induced and the woman placed in all the possible risks of that period. Probably a neurotic constitution was an essential prerequisite for the development of post-operative insanity. For illustration of the possibilities even without operation, he reported a case of mental disturbance for menstruation, in a woman with good family history, where no operation had been performed. He calls attention to the fact that the normal functions of the uterus and ovaries are themselves not unassociated with mental aberration; alterations in the temper, actual hallucinations, disordered appetites of all kinds were occasional accompaniments of these perfectly normal processes.

SATURDAY, MARCH 16, 1901.

REORGANIZATION OF THE BRITISH MEDICAL ASSOCIATION.

The need of a better organization of physicians is felt in the United States, where the disadvantages of an ununited profession in the struggle against united quackery, and other evils, are every day manifest. In other countries similar evils are to be fought and like needs for organization exist; therefore, we hear of movements in the direction of furthering professional interests, such as business association, etc., in almost every quarter of the globe. Organizations and combinations are the special feature of the present day, and medicine can not be an exception to the rule. Organization to meet the new conditions as they arise is the essential to success, and this fact is apparently being more generally recognized now than at any time in the past.

The British Medical Association has been taking steps, through a strong committee, toward its reorganization, and the recommendations of the committee—its first or provisional report—are given in a supplement of forty-eight closely printed pages of the *British Medical Journal* of February 16.

At the present time the British Medical Association has, as an essential element, a system of local organizations called Branches, in which only about two-thirds of the members of the Association are included. It transacts its affairs in General Meetings and through the Council, the latter being partly representative and partly created in such a manner as to make it more or less perpetual. The powers of this body are ill-defined, although it practically controls all the affairs of the Association, the wishes of the General Meeting, as expressed by resolutions, not being necessarily respected. Nevertheless, the will of the General Meeting, if an attempt were made, would legally override that of the Council. Regarding this, the committee says: "The powers thus possessed by the General Meetings, though their exact extent has been for some years in dispute, are unquestionably great, and in view of the essential unfitness of such meetings for such duties, are a source of danger to the Association. In any association of 18,000 persons, it is impossible that all should attend a General Meeting; in the British Medical Association it is impossible that more than a very small proportion should attend such a meeting; those who attend do so on their own account without any authority or power to represent others; and thus the decisions of a very small assembly whose composition is quite fortuitous stand legally as the decisions of the whole Association. This applies to every question of policy whether concerning the internal affairs of the Association or the general interests of the profession." The committee therefore suggests that this condition should be changed. The Association, it says, has outgrown its present limitations and its plan of organization, which has not been changed since 1874.

The recommended organization includes primary units or Divisions, corresponding as nearly as possible to parliamentary districts or constituencies. A certain number of these are grouped to form a more comprehensive body called a Branch, numbering not less than 200 members. All memberships in the Association must be through these Divisions. It will be one of the duties of the Division delegate to keep a list of all the medical men in his Division territory and act as a recruiting officer for the Association. The Branch is to supervise the Division, and still above it is the General Council, made up of the delegates from the respective Branches and the general officers of the Association, subject in some respects only to the general annual business meeting. If, in its judgment, any resolution adopted by the annual general business or delegate meetings does not properly represent the wishes of the Association, it can, within certain limits as to time, refer it with its own views thereon to the consideration of the special meetings of all the Divisions, and in that case the said resolution would not be valid or binding unless it received the approval of the majority of the members present and voting in the said special meetings of the Divisions. This is the referendum feature of the plan, which, as we understand it, is a final check on the Council in all business and other matters of importance. Provisions are made for details of voting, office holding, subscriptions, etc., but the above are the leading features of the proposed reorganization that are of interest to us. On the whole, the plan seems to be a good one.

Possibly the scheme thus tentatively set forth will be more or less modified, but the fact that it has been prepared as an attempt to meet needs that exist is of interest. It is evidence that a better organization in the medical profession is a recognized necessity in Great Britain, and it may be valuable in a suggestive way to the profession in this country. It is evident that there are some difficulties ahead if the plan is to apply to England's dependencies, and some of them do not appear to us to have been fully considered. The medical profession in the Dominion of Canada, for example, would be much more advantageously affiliated with a well-organized profession in the United States than with one in a distant island with which they are only politically connected; and equally serious disadvantages appear to us possible in the government of an Antipodean profession by a predominantly insular organization. The world has not yet grown so small that distance is altogether annihilated, and sentimental British imperialism may prove less influential than local interest and feelings. A thorough local organization, however, with a general central control of such extent as will co-ordinate and economize effort, seems to be one of the best methods of meeting the needs of the profession as they arise, and such a plan as above indicated ought to fulfil this indication, perhaps better than any other.

The British Medical Association is to be congratulated on having a committee which took hold of the matter so thoroughly, and which has taken the time to present such an exhaustive and complete report. The result will be watched with interest by many on this side of the Atlantic.

PARASITIC HEMOPTYSIS.*

The discovery of the lung fluke in hogs in this country has led the zoologists of the Bureau of Animal Industry in Washington to collect the principal facts in regard to this parasite and to bring the chief features of the human form of this infection to the attention of practitioners. The disease is not discussed in our works on practice, and as cases are liable to appear in this country and to be imported by soldiers returning from Asia, we certainly owe thanks for the timely warning. As pointed out by Stiles,[1] zoology and human and comparative medicine are three closely allied callings, and the medical profession should not be backward in recognizing its indebtedness to the labors of zoologists and veterinarians.

The lung fluke is known under various names, the correct one, according to Stiles, being Paragonimus Westermanni. Perhaps the most frequent synonym is Distomum Westermanni, which is the term used by the Japanese pathologist Katsurada in a recent and valuable article.[2] Discovered by Kerbert in 1878, in a tiger, it was found afterward in man, in Formosa by Ringer, in Japan by Baelz and others. Since then it has been found in various parts of Japan, China, and Corea. The American zoologist, Ward, found it in the cat and dog, and lately it has been found in hogs by the inspectors of the Bureau of Animal Industry. It is in Japan that the disease is most common in man, there being, according to Katsurada, quite a number of endemic foci in that country, no region of which is wholly free from the infection.

The complete life cycle of the lung fluke has not yet been demonstrated. The eastern physicians regard the water-supply and mollusks as the sources of infection. Encysted or free-swimming larval forms (cercaria) will in all probability be the stage in which the parasite enters its final host—man, cat, dog, tiger, hog (Stiles). The manner in which the worm, 8 to 16 mm. long, 4 to 6 mm. broad, 2 to 5 mm. thick, enters the lung is not known. Once here the eggs are laid, which may be expectorated as such and which do not develop until they have left the host. Some observers describe the development of a ciliated embryo—miracidium—from eggs subjected to a temperature of 30 C. The fate of these embryos under natural conditions is not yet known.

The disease in man, produced by Paragonimus Westermanni, was named parasitic hemoptysis by Manson in 1880, and this is the name it seems destined to bear in English literature. As indicated by the name, hemoptysis is the chief clinical symptom. The sputum is dirty red to brown, due to the presence of the eggs, which are microscopic—about 80 to 100 mikrons long and 48 to 60 broad. Blood is present intermittently; cough is common, but not constant. As many as 12,000 eggs may be expectorated daily. It is evident that unless careful microscopic examination of the sputum is made the cases would naturally be mistaken for tuberculosis. The eggs are oval, brownish-yellow, one end being broader than the other, and provided with a thin shell. The contents are surrounded by an additional membrane and show a clear, rounded body, granular cells and clumps. The disease does not appear to be very dangerous as to life. Katsurada, in a community in which the disease is endemic, found the parasites in the lungs in but four of the cadavers subjected to autopsy in his institute. Recovery may occur and patients live for years if the eggs are confined to the lungs. Embolism of worms and eggs into the brain may take place, and cases of Jacksonian epilepsy due to this cause are described by Yamiagiwa, Katsurda and other Japanese observers. This event renders the prognosis unfavorable.

The pathologic changes have been studied, especially in Japan. Katsurada describes the lesions in four cases. Small cavities or cysts are found in the lungs, particularly under the pleura, surrounded by newly-formed tissue and containing the worms and their eggs together with detritus. The cavities communicate with bronchi, a fact that seemingly points to the bronchial tubes as the routes of entrance. It is thought that the hemorrhages result from the rupture of capillaries and smaller arteries in the walls of the cavities. The granulation tissue in the walls of the cavities not rarely contain multinuclear giant cells, which Katsurada regards as foreign body giant cells. Areas of scar tissue are also present in affected lungs. In the brain the embolized ova produce a multiple cortical encephalitis with giant cells. Similar foci containing eggs have been found in the liver, mediastinum, diaphragm, and elsewhere.

The lung fluke disease being present in the dog, cat and hog in this country, it stands to reason that infection in man may occur. Perhaps unrecognized cases already have occurred. So far no specific treatment is known. The underlying principles of an intelligent prophylaxis are indicated in what has been said in the foregoing. Stiles advances the existence of this disease as an argument for courses in tropical medicine, and certainly opportunities should exist in this country for training men for medical duties in the tropics.

THE LATERAL-CHAIN THEORY OF IMMUNITY

Long before the day of bacteriology it was known that an attack of some diseases conferred protection from subsequent attack by the same disease, and various more or less fanciful explanations of this phenomenon were offered. As, gradually, it became known of a number of diseases that they were due to the action of minute forms of vegetable life, better crystallized conceptions of the disease-process, as well as those of recovery and immunity, were possible. The morbid process may be attributed to the reaction between the tissues of the invaded body and living vegetable cells, together with the products of their vital activity, and recovery and immunity, when they occur, may be considered merely as phases in this process, as a result of something added to or abstracted from the body. Much difference of opinion has existed and much discussion has been waged as to how recovery is brought about and immunity is induced. In order that the first event shall take place it is necessary for the invading bacteria to be destroyed or eliminated, and for the establishment of the second, either an antitoxin must be introduced from without or generated within the body; and it is with regard to the manner in which these results are brought about that agreement has been wanting. Of the several views put forward, that of Ehrlich has, perhaps, been received with greatest favor. This is known as the lateral-chain theory of immunity. It is based largely upon experimental evidence, and affords an ingenious explanation of the processes that are supposed to take place in the development of immunity following recovery from infectious diseases acquired naturally or induced artificially.

The cell is believed to consist of a nucleus, or central group, and to be provided with various lateral processes—in the sense in which these terms are used in organic chemistry. The cell may be injured by the entrance of the poison generated by the bacteria, in accordance with its chemical affinity, into combination with one of the numerous processes, which it does not destroy, and from which it is separable under certain conditions. This relation, which is established through a special molecular group of the toxic body, constitutes the channel through which the actual poison exerts its influence upon the central group, whose disturbance represents the true disease. If this influence is excessive the central group dies; otherwise it will do what it is physiologically accustomed to do, viz., throw off the process that has become unnecessary for its existence—by combination with the poison—and replace it by a new process—a regenerative procedure that, like all such processes, is completed only through redundancy of growth; or, as is thought by some, the detached and greatly increased lateral-chain material breaks up the combination between the poison and the cell. In this way active immunization is brought about. The chain substance generated in excess to replace chains that have become useless, and thrown into the circulation, also represents the antitoxin, which, after recovery from disease, enters into combination with the toxin by reason of its clinical affinity, and, thereby, after recovery from disease acquired naturally or induced artificially, protects the individual against the poison introduced and thus renders him immune. The blood serum of such a person, impregnated with lateral chains, is also capable, if introduced into a second person, who receives the toxin in question, of neutralizing the latter, or, if introduced subsequently to the poison, combining with it. Immunity depends upon chemical combination of the toxin with the antitoxin. In the process of active immunization the body itself prepares the immunizing material, while in passive immunization the body receives the material from an actively immunized body. In the first event the cell-body is active; in the second it is not called upon. When the cell-body has generated antitoxin for a long time the immunity is more protracted, but in the second event only so long as antitoxin can be believed to be still present in the blood. As the combination depends upon chemical affinity the immunity is specific. Only that one among the many lateral chains neutralizes the toxin that is capable of uniting with it by reason of its chemical affinity, and this relation is mutually reciprocal. The production of the immunizing substance is attributed to a nutritive function of the central group of the cell, but passive immunization is provided with the weapon for its defense by active immunization from the material that this has produced in excess of its own needs.

The lateral-chain theory of immunity has been invoked to explain also the elimination of the bacteria that must take place in order for recovery to occur. It is, accordingly, assumed that the bacteria, in accordance with their chemical constitution, cause the throwing off of a lateral chain which unites with the protoplasm of the bacteria and through the intermediation of one of its complexes attracts a fermentative substance contained in the serum which effects a solution of the bacteria.

HAZING AND MEDICAL COLLEGES.

A recent occurrence in an eastern medical college does not speak very highly for the maturity, manliness and scientific spirit of the undergraduates of the institution. A professional school is generally supposed to be free from some of the idiotic puerilities that have been so frequent in institutions for primary culture, and hazing, we had supposed, was being left in the remote past by men who had gone far enough to choose the profession of medicine. The student, however, in the college referred to, who was maltreated in a certainly unpleasant and mortifying way, and who brought his tormentors into a police court, has been ostracized, it is said, by the whole school, including his own class. The transaction does not reflect any special credit on these students.

MISSOURI'S NEW PRACTICE ACT.

While the medical practice act that has just passed the Missouri legislature is in the line of progress generally, it is to be regretted that it gives to masseurs, who call themselves osteopaths, a legal right to treat the sick in that state. Osteopathy, however, is a Missouri product, and special influences were doubtless at work in its behalf. One of the legislators, opposing the bill as a whole, in a published statement calls attention to the point that ought to have been manifest to others of his colleagues. He asks: Why are physicians of the recognized schools obliged to be examined and to pay for the privilege, while osteopaths are exempt? The bill, he says, discriminates against all schools of medicine except osteopathy, and therefore is class legislation. It would be a pity if this alleged fact should balk the purpose of the act. as he says it will, on the ground of unconstitutionality. These masseurs certainly ought to be subjected to some regulation, even in Missouri, where this latest moonshine product originated.

CONSUMPTION CURES.

Since public attention has been focused upon tuberculosis, the number of consumption cures has multiplied almost daily, and in the editorial advertisement of one of them, in a New York paper, their number up-to-date is given as 153. They range from burying in carrion, which is perhaps the most repulsive, through every possible form of remedial treatment up to the metaphysics of "Christian science," and human credulity would seem to be pretty nearly exhausted, if it were not actually inexhaustible, on this subject. It is a curious inconsistency of the human mind that it can take in at once the terror of an incurable disease, and this belief in the multiplicity of its cures. It is in fact a snatching at straws in many cases. Consumption is not an incurable disorder, and probably many more patients with tuberculous infection recover than succumb to the disease, but this is due to hygienic conditions and natural resistance; at least it has been so in the past. At the present time we are learning to utilize well-known principles in combating this disease, but specific medication for its cure does not seem to be as yet on any scientific or well-established clinical basis, though, as a lay paper says, "it is a cold day when there is no consumption cure announced."

BIOLOGIC TESTS OF THE PROTEIDS IN VARIOUS MILKS.

The most important nutritive substances in milk are the proteids. It is of essential importance for the perfection of substitutes for mother's milk that the nature of the proteid constituents of various milks is understood more clearly than heretofore. The question whether the proteids in the milk of various animals are identical may be a very important one indeed. In order to gain some insight into this problem Schütze[1] resorted to the method suggested by the experiments of Bordet, Metchnikoff and others on hemolysins, spermotoxins, etc., and injected one lot of rabbits, at frequent intervals, with increasing doses of sterilized cow's milk, a second lot with goat's milk, and a third with the milk of a woman. After about three weeks of this treatment the serum of the rabbits acquired the power of coagulating the milk with which it had been injected. But this power is specific in the sense that the serum of rabbits treated with cow's milk coagulated cow's milk only and not goat's or woman's milk, and vice versa. This shows conclusively that the proteid molecules of various milks differ from one another. It was long ago learned that patients do not utilize the milk of various animals in the same degree, some doing better than others on the same milk. Schütze also found that when milk is boiled for half an hour it is no longer coagulated by its specific lactoserum, thus demonstrating that heat greatly modifies the molecular structure of the proteids. It remains to determine the exact degree of heat necessary to sterilize milk without causing much or any change in the structure of its proteid molecules. It seems that each animal species has its own peculiar milk, and it must be regarded as settled that it is impossible to make preparations from cow's milk that will have the same composition as human milk. At the same time it is not denied that artificial feeding may give excellent results. Lactoserum may become, however, an important agent in determining the degree of exact composition of the proteids in the various preparations offered as substitutes for human milk. This biologic test again shows the manifold variety of the products of cells, and in a much more striking manner than the chemical analysis has been able to do up to the present time. It seems that Fisch,[2] by analogous experiments, obtained similar results to those of Schütze. The field offers many inviting opportunities for further studies.[3]

THE GERM OF SMALLPOX.

The germ of smallpox has heretofore received no general recognition, though the conviction that variola is a germ disease is unavoidable. The latest on this subject is to be found in the *British Medical Journal* for February 23, in which are two communications bearing on this subject. Dr. M. Funck, director of the Institut Sérothérapique, and chief of the bacteriologic laboratory of the University of Brussels, reports the results of his studies in this direction and the finding, in vaccin and smallpox pustules, of morphologically identical organisms which he considers as the cause of vaccinia and variola. These appear under three forms, representing different stages of the same protozoon: 1, an isolated green sphere showing slow movements: 2, the same infecting epidermic cells, and 3, a morula form consisting of agglomerated sporoblasts; the last is the one most frequently found in old vaccins, while the first form is more common in perfectly fresh material. The inoculation of these organisms into susceptible animals produced all the symptoms of vaccinia and the subsequent immunity. In the pustules of confluent smallpox the same elements were found and their behavior will be described in a forthcoming paper. From these facts, Funck concludes that variola and vaccinia are identical, that vaccinia is only the attenuated form of smallpox, and that the immunity it produces is not an exception to the general laws of specific immunity. The discovery of the protozoon is not claimed as a new one, as its presence in vaccin corpuscles was recognized by L. Pfeiffer—in 1887—whose work is highly spoken of by Funck. That bacteria are not the active agents in vaccinia the author considers proved by the fact that he finds vaccin matter after a certain period absolutely free from microbes, though still active, and the pustules thus produced are also themselves sterile. This seems to have some important practical bearings and probably explains the well known better action of ripened vaccin. The second communication is by Monckton Copeman, medical inspector to the local government board in England, who describes zooglea-like masses found in collodion capsule cultures of vaccin lymph sealed up and placed within the peritoneal cavities of rabbits and dogs, the method being the same as that followed by Nocard and Roux in studying the micro-organisms of bovine pleuropneumonia. The fluid contents of these capsules was found capable of producing typical vaccinia in the calf. He has since demonstrated apparently similar organisms in genuine smallpox in man. Whether these zooglea masses are the same as the third type of manifestation of the sporozoon of Funck is not entirely clear, but they are described as "made up of bodies resembling spores, only the periphery of which took the stain." There is no record of the detection of any actual microbe. It seems possible that we will at least have light thrown on the etiology of this disorder, the first in which artificial immunity was secured, but one of the last so far to evade our search for its germ.

THE SURGICAL TREATMENT OF ASCITES DUE TO CIRRHOSIS OF THE LIVER.

It is taught generally that ascites in cirrhosis of the liver is due to mechanical obstruction of the portal circulation. Where the portal congestion is relieved through existing collateral channels, ascites may be absent. Cases of cirrhosis with ascites have been recorded in which the formation of more or less extensive peritoneal adhesions, due to repeated tappings or other causes, has been followed by recovery from ascitic accumulations. Ascites in cirrhosis of the liver may be regarded, then, as an indication that sufficient collateral circulation can not be established spontaneously, most likely on account of absence of some of the natural but inconstant communications between the portal system and the general venous system. Packard and LeConte[1] discuss the surgical treatment for the relief of the ascites of cirrhosis, brought to the attention of physicians by Talma, and first carried to a successful issue by Drummond and Morison. The various methods employed all aim at producing a collateral circulation through peritoneal adhesions. Packard and Le Conte have collected, from the literature, twenty-two cases in which surgical measures were resorted to for relief of ascites. The actual results are difficult of succinct statement, but contrasting the worst view with the best construction there is found an operative mortality somewhere between 23 per cent. and 7 per cent., and the recoveries run between 41 per cent. and 64 per cent. These statistics can not be regarded otherwise than as encouraging. The method is still on trial, and an accurate estimate of its value is not yet possible. Enough has been learned, however, to show that surgical treatment of ascites in cirrhosis is not absolutely contraindicated for the reason that removal of ascites is directly detrimental to health and life; for it has been urged by some that ascites in cirrhosis is an expression of toxemia, and that its removal would not tend to benefit the patient. Le Conte recommends that an incision be made to the left of the median line, under local or chloroform anesthesia, and that the parietal peritoneum over the liver, spleen and omentum be dried and gently rubbed with a gauze sponge, the same treatment being applied also to the surface of the organs, and the omentum stitched to the anterior abdominal wall with two or three stitches of catgut. In the meantime the ascitic accumulation may be drained off through a suprapubic opening in which a drainage-tube may be left if the latter can be cared for properly. Otherwise both wounds should be closed at once. Drainage is regarded as useful for three or four days until the adhesions become firm, but great care must be used to prevent infection. Packard and Le Conte conclude that the operation has won a distinct place, and that in the future the suitability of particular cases for the operation may be more clearly established than is the case at present. They recommend the operation in cases of pure portal cirrhosis where persistent and well-directed medical treatment is followed by insignificant results. As yet operation is not indicated in other forms of cirrhosis. In the diagnosis of cases for contemplated operation, care should be taken to eliminate syphilitic cirrhosis, in which recovery is possible under proper medicinal treatment. The relief of ascites in patients with atrophic cirrhosis would be a blessing, as otherwise constant treatment and repeated tappings are necessary and the sufferers are doomed to perpetual invalidism. The earlier the relief comes, the better, because then the liver has more of a chance to regain its functions by compensatory hyperplasia in the event that the process of contraction is brought to a standstill.

GERMAN ANTIVIVISECTION BIGOTRY.

The Prussian cultus minister, it is said, has established a detective bureau to watch all medical literature for cases of questionable operations and experiments. It is evident that the antivivisection bigotry and outcry against fictitious cruelties is not entirely confined to America, and there is some comfort in the recognition of this fact, though it does not cause any serious discomfort here so long as the antivivisectionists are unable to interfere with perfectly legitimate work, as in their ignorance they are inclined to do. The Germans have one advantage over us, however, in that these misguided enthusiasts have not been able there to interfere with necessary sanitary measures, such as vaccination, as they have to some extent in this country and in Great Britain.

Medical News.

CALIFORNIA.

A quack was recently fined $100 in Los Angeles for practicing medicine without a license.

In San Jose, a man who has been travelling through the state under the title of the "Old Quaker Doctor," has been arrested, the result of investigations by a joint committee from the Pastors' Union of San Jose and the Santa Clara County Medical Society.

Three "Indian doctors," who secured the deeds to a ranch near Santa Rosa in exchange for an alleged practice in that place, and who were sued on account of misrepresentations, have been defeated in court, the deeds to the property annulled and the ranch returned to its original owners.

DISTRICT OF COLUMBIA.

Honorary Membership.—The Imperial Medical Society of Constantinople, Turkey, at its [illegible], elected Surgeon-General Wyman, of the [illegible] Service, to honorary membership. This is the oldest scientific body in Constantinople, has done much to improve the sanitary condition of the Empire of Turkey, and, as an aid to its work, receives the patronage and protection of the Sultan.

GEORGIA.

Waycross, on account of the prevalence of scarlatina, has decided to prohibit public gatherings of all kinds, including religious services, for two weeks.

A hospital for incurables was opened in Atlanta, March 2, by the Atlanta Circle of King's Daughters and Sons. It has accommodation for ten patients and is under the medical charge of Dr. James M. Brawner.

Smallpox in Atlanta is to be under the control of hospital and charities committee of the city council, provided the ordinance committee's recommendations are approved by the council. This will make the position of the local board of health rather an anomalous one.

In Atlanta, four physicians who inspected cases of smallpox were paid $190 each for the service, or at the rate of $5 a visit. The council reversed its action and requested a refund. Two doctors complied, and now the council has passed an order returning the amount refunded.

ILLINOIS.

An isolation hospital, to cost about $3000, is to be erected in Springfield.

Smallpox is reported in Anna, 50 cases; Belleville Township, several cases; Cogden, 1; Petersburg, 1 new case, and Tallula, 1 case.

The Galesburg Sanatorium has been incorporated by Dr. Ewing Van D. Morris, H. M. Chase and Fred H. Holmes, with a capital stock of $75,000.

Typhoid fever is epidemic in Rock Island. The health officer, Dr. George G. Craig, Jr., reports 376 cases of the disease between Nov. 1, 1900, and March 1, 1901. He claims that the infection is due to city water and urges that the inlet pipe be examined.

Reporting death.—A bill introduced in the assembly, March 7, provides that it shall be the duty of every surgeon who performs a surgical operation and of every physician who advises and arranges for the same, after which death results within thirty days, to report the same to the coroner of the county within twenty-four hours. It shall be the duty of the coroner to call a competent physician, who has had no previous connection with the case, to make a thorough investigation of all the circumstances before the coroner's jury and report the same as the statute provides in other cases. Violation of the provisions is made a misdemeanor punishable by a fine of $500 or thirty days' imprisonment.

Chicago.

Michael Reese Hospital was recently damaged by fire to the extent of $2000.

Dr. Christian Fenger, on account of distinguished service rendered in the United States and abroad, has been made a Knight of Dannebrog, by King Christian of Denmark; and has received the cross of that order.

Smallpox.—Only 9 new "suspect" cases of smallpox were reported during the week ended March 9 of which 7 were verified, and 6 of these were removed to the Isolation Hospital and 1 quarantined with the family at home. The mild type of the disease remains unchanged, only 1 death having occurred in the 134 cases treated since Nov. 30, 1900. The situation no longer causes the health department any anxiety.

Vital Statistics.—The mortality for the week ended March 9 was 478, equivalent to an annual death-rate of 14.18 per 1000. The chief causes of death were: respiratory diseases, including tuberculosis, 196; heart diseases, 38; nervous diseases, 31; Bright's disease, 25; violence, 26. An excess of 44 deaths over the number recorded for the week previous is interpreted by the health department as the beginning of a period of rising death rates after six weeks of unprecedentedly low winter mortality. Increased frequency of the germs of pneumonia and influenza in the laboratory examinations made for physicians indicates these as the diseases to be most dreaded and to be most guarded against.

Effects of Weather.—March weather is proverbially trying in Chicago and the catarrhal condition caused by raw winds, dampness and sudden changes of temperature favors the growth and activity of the germ of all diseases of the throat and air-passages. Hence the health department cautions against exposure to cold and wet, to the debilitating effects of overheated and poorly-ventilated rooms, street-cars and other places; and, the desirability of undereating rather than overeating at this season of the year. The observance of Lent in its dietetic feature, is a sound hygienic measure, in the opinion of the department.

INDIANA.

Dr. Hiram W. Bowman, St. Joe Station, has been appointed coroner of De Kalb County.

A public hospital is to be established in Bloomington, and the committee which has the matter in charge already has a fund of $3000.

Smallpox patients have filled the Indianapolis Isolation Hospital, and the board of health is now considering the problem of the disposition of additional cases. There are now fifty-three persons under quarantine in the city.

Indiana Medical College, Indianapolis, is to have a new building four stories in height, thoroughly equipped, heated by steam and lighted by electricity. The building committee has awarded the contract which calls for a completion of the building by September 1.

IOWA.

The County Hospital of Louisa county, at Wapello, has been completed at a cost of $10,000. It is thoroughly furnished and equipped and is ready to receive patients.

The Fairfield Hospital Association has named as members of the medical board of the hospital, Drs. J. Fred Clarke, Calvin Snook and John V. Bean, Fairfield, and Dr. Samuel K. Davis, Libertyville.

A tract of land, 200 by 300 feet, was donated by the city council of Cedar Rapids, March 9, as a site for a hospital, which is to be erected this season by the Sisters of Mercy, at a cost of not less than $50,000.

Dr. Marion R. Hammer, Newton, was found guilty of assault with intent to commit murder, March 2; the motion for a new trial was overruled, and he was sentenced on March 5, to 3½ years in the penitentiary at Fort Madison.

The medical department of the state university, at Iowa City, suffered to the extent of $200,000 by fire March 10. The medical building was entirely destroyed. As the school would have closed in three weeks, its work for the year will not be seriously crippled.

KANSAS.

Dr. Frank McCallum, Kansas City, who went as volunteer to the Philippines two years ago, has been made captain and assistant surgeon of volunteers.

One thousand cases of smallpox in the state, and 500 of these in Crawford and Cherokee counties, are given by the secretary of the State Board of Health as the number on March 7.

The State Board of Health has been named by the governor, and the recommendation sent to the senate for approval. The following are nominees: Dr. S. Jay Crumbine, Fort Dodge; Robert J. Morton, Greent; B. J. Alexander, Hiawatha; S. W. Williston, Lawrence; G. W. Hollembeak, Cimarron, and others.

MARYLAND.

Baltimore.

Dr. Aaron Friedenwald has been elected president and Dr. Abraham B. Arnold, treasurer of the Baltimore branch of the Alliance Israelite Universelle, for the ensuing year.

The Woman's Medical College celebrated the twentieth anniversary of its founding, February 22, at the college building. The committee in charge of the exercises consisted of Drs. Eugene F. Cordell, John G. Jay and Pearce Kintzing.

Mortality Rate.—The mortality from pneumonia and bronchitis has created alarm. Many physicians attributed it in large measure to unheated street-cars. From Nov. 1, 1900, to Feb. 18, 1901, there were 498 deaths from pneumonia and 102 from bronchitis. During the present session, 45 cases of pneumonia have been admitted to the Johns Hopkins Hospital, with a mortality of 28.8 per cent. Seventeen recovered by lysis.

Appointment.—Dr. Clarence B. Farrar, a graduate of the Johns Hopkins University, has been added to the staff of the Sheppard and Enoch Pratt Hospital for Nervous and Mental Disease, as clinical and laboratory assistant, and provision has been made for young graduates of medical schools, as resident assistant physicians, that they may devote themselves to the special study of nervous disorders. An effort is made to exclude all but curable patients, although a few chronic cases are temporarily admitted. The net amount received from the bequest of Enoch Pratt, after the expenses of the litigation, was $1,069,300.

Hazing by Students.—There has been trouble at the University of Maryland's School of Medicine, on account of the hazing of a freshman, who, in the dissecting room had his mustache cut off with a pair of dissecting scissors. By the advice of the Dean, as he says, he had the offender arrested and fined. This created bad feeling, and he was pelted with rotten eggs and other articles and roughly jostled on attempting to attend lectures. The medical faculty has passed resolutions forbidding the practice of hazing and authorizing the dean to suspend any student found guilty of maltreating, molesting, or in any way interfering with, any other student. The hazee now announces that he may resume his studies in a few days.

MASSACHUSETTS.

Dr. Richard H. Thompson, Malden, has been appointed city physician.

The Emergency Hospital at Springfield was opened February 26, and is under the charge of Drs. E. V. Hardwick and R. W. Brayton.

A state sanatorium for consumptives is the aim of a bill introduced by Senator Fitzgerald, which appropriates $150,000 for this purpose. The sanatorium, if established, will probably be located in the mountains in the western part of the state.

The Hospital for Consumptives, Boston, will be located on Marcella Street, and the mayor has recommended an appropriation of $80,000 for its equipment and maintenance. There are now four institutions in Boston where consumptives receive free treatment.

MICHIGAN.

Two health officers, Dr. Michael D. Ryan, president of the Saginaw Board of Health, and the health officer of Gilmore Township, Isabella County, are ill with smallpox.

Dr. Beverly D. Harison, Sault Ste. Marie, secretary of the State Board of Health, who was not reappointed by Governor Bliss, refused to surrender his office and was sustained in his claim by Attorney-General Owen, who holds that the term of office does not expire until October

The Health of Michigan.—For the month of February, compared with the preceding month, pneumonia, pleuritis, inflammation of the kidney, scarlet fever, erysipelas and whooping-cough were more prevalent; and typhoid fever, inflammation of the bowels, intermittent fever, diphtheria, smallpox and measles were less prevalent.

By the will of Mrs. Palmer, who died March 7, and who was the widow of Dr. A. B. Palmer, of the medical department of the University of Michigan, Ann Arbor, $20,000 is bequeathed to build a new ward in the hospital, and $15,000 for the maintenance of free beds in the institution.

The state contagious disease inspector, Dr. George E. Ranney, Lansing, has gone to Boyne Falls, to investigate a smallpox epidemic at that place. The disease has been diagnosed by an outside physician as chicken-pox, and the lumbermen are said to be determined to break quarantine and threaten to fight their way through if they are opposed.

MINNESOTA.

Medical inspection of schools in Minneapolis, by volunteer inspectors, commenced March 11.

A detention hospital for the temporary care of persons insane, or supposed to be, was advocated by the Ramsey County Medical Society at its last meeting.

A bill has been introduced, authorizing practicing physicians to compound medicine under the same restrictions placed on druggists without securing pharmacists' licenses.

The license and control of massage and bath parlors, faith healers and mind readers is provided for in a bill providing that the council or other governing body of any city or town may prescribe license fees and reasonable rules for their control.

The report of Health Commissioner Dr. John M. Robinson, Duluth, shows that 98 per cent. of the smallpox patients in the city had not been vaccinated within seven years, and that 267 out of the 309 patients, or 86.4 per cent., had never been vaccinated.

MISSOURI.

Lutheran Hospital, St. Louis, recently opened its new ad- [illegible] oms for private patients, a modern [illegible] dining-rooms for nurses, etc. It has been furnished by various organizations connected with the Lutheran churches of the city.

The Hall medical bill has passed house and senate and now awaits the signature of the governor to become a law. The opponents of the bill employed all the obstructive tactics known to adroit parliamentarians, without avail, and now the "Christian Scientists" have given up the fight and retired from the field.

Hospital Staff.—The German Hospital, Kansas City, has the following medical staff for the year: Drs. Julius Bruehl, Charles H. Lester, Robert T. Sloan, Lincoln G. Taylor, Charles F. Wainwright and Isadore J. Wolf, on the medical side; Drs. Jacob Block, George O. Coffin, Andrew L. Fulton, George Halley, Louis W. Luscher, and E. Van Quast, on the surgical side; Drs. Blencowe E. Fryer and John H. Thompson, oculists and aurists.

MONTANA.

A military hospital, with a capacity of twenty beds, is to be built at Fort Keogh, near Miles City.

The bill to create a state board of health has been favorably considered by the house in committee of the whole, the compulsory vaccination clause being stricken out.

In Helena the members of the board of pension examiners have resigned on account of the unreasonable and unnecessary work required and the unreasonably small fees allowed.

The osteopathy bill has been passed with amendments by the senate, the amendment making it a misdemeanor to prescribe medicine while practicing under the osteopathy law, by a person not a regularly licensed physician.

NEBRASKA.

A state health inspector, with a salary of $1800 a year, is created by a bill which provides for the organization of county boards of health, to prevent the spread of contagious diseases. The bill leaves the compensation of the county inspector to the liberality of the county board.

An ultimatum has been promulgated by Health Commissioner Dr. Victor H. Coffman, Omaha, in which he calls the attention of physicians to the fact that it is the duty of the health department to take cognizance of all sudden deaths, accidents and emergency cases. The police and health departments are to be notified, and physicians who fail to give notice to the health commissioner are subject to fine.

Medical Staff.—The medical staff of the County Hospital, Omaha, is as follows: Drs. Andrew W. Riley, Salon R. Towne, Willson R. Bridges and William F. Milroy, medicine; Drs. John E. Summers, Jr., Charles C. Allison, H. P. Hamilton, August F. Jonas and John C. Anderson, surgery; Dr. Charles Rosewater, obstetrics; Dr. H. Clayton Sumney, dermatology; Drs. Harold Gifford, Henry L. Burrell and Henry B. Lemere, ophthalmology and otology, and Drs. Ewing Brown, Fred Rustin, gynecology.

NEW JERSEY.

Dr. Daniel M. Dill, Newark, has been appointed superintendent of Essex County Hospital for the Insane.

Dr. Francis W. Bennett has been appointed surgeon and physician to the Pennsylvania Railroad Company, at Atlantic City.

Mob law ruled in Orange, March 11, when the isolation hospital which is being erected by the board of health, was demolished.

Dr. Chauncey V. Everitt, Jersey City, has been appointed city physician in succession to his father, Dr. John R. Everitt, who resigned.

Medical Library at Orange.—By the generosity of the widow of the late Dr. William Pierson, the physicians of the Oranges have become possessed of a library of 8000 volumes. For the present the books will be placed in the building in course of erection to the memory of Dr. Joseph William Stickler, whose estate contributed another library of value along other lines. The local physicians have named a committee of organization, to report, at an early date, on a plan embracing lecture halls as well as accommodations for readers.

NEW YORK.

Dr. Joshua J. Sweet has been appointed health officer of Unadilla.

Dr. Charles D. McCarthy has been appointed health officer of Geneva, for a term of three years, at an annual salary of $300.

Utica has appointed fifteen ward physicians who, with two exceptions, receive a salary of $100 per annum, the two receiving $125 each per annum.

The January deaths in the state numbered 12,524, or 2000 above the average, the deaths from acute respiratory diseases being 2720. There were 2570 deaths at and above the age of 70 years—as many as under 5 years.

Influenza in New York.—The State Board of Health has issued a statement relative to the prevalence of la grippe in this state, since its appearance in 1889. The number of deaths each year, from the disease, is as follows: 1890, 5000; 1891, 8000; 1892, 8000; 1893, 6000; 1894, 3000; 1895, 5000; 1896, 2750; 1897, 3000; 1898, 2500; 1899, 7000; 1900, 11,500. The affection has varied greatly in severity in different years; it seems likewise to have varied in virulence in different localities and to have shown various types, likewise in the rapidity of its spread. It is evidently communicable from the individual directly, possibly immediately, and conveyed in infected clothing. Like all zymotic diseases susceptibility to it varies; unlike some, immunity does not follow a previous attack. The state is now in the course of the twelfth recurrence of the disease, affecting the mortality of December by about 300; it increased the number of deaths in January by probably 3000, and was still progressing during February.

German Hospital.—This Buffalo institution was opened to the public on March 10. The building reflects great credit on the German citizens who have worked so unremittingly in behalf of the institution. The hospital will be non-racial and nonsectarian. The following staff is announced: Internal medicine, Drs. Conrad Diehl, Emil S. Tobie and Thomas Lathrop consulting, and Drs. Henry C. Bushwell, William C. L. Meisburger, Julius Ullman and Robert Hebenstreit, attending; surgery, Dr. Roswell Park, consulting, Drs. Marcello Hartwig, Herman Mynter, John G. Meidenbauer and Henry G. Bentz, attending; gynecology, Dr. Matthew D. Mann, consulting, Drs. Charles H. W. Auel, Max C. Breuer, Herman E. Hayd and Sigmund Goldberg, attending; obstetrics, Dr. Charles H. W. Auel, consulting; diseases of children, Drs. Ludwig Schroeter, Charles Weil and Herriott C. Rooth; eye and ear, Drs. Lucian Howe and Julius Pohlmann, consulting; Dr. Jacob Goldberg, attending; nose and throat, Drs. George F. Cott and W. Scott Renner, attending; skin, Dr. Ernest Wende, consulting, Drs. Grover W. Wende, Jacob M. Kraus and Alfred E. Diehl, attending; genito-urinary, Drs. Alois Joki and Julius Reister; *nervous*, Drs. William C. Krauss, Floyd S. Cregs and Herman G. Matzinger; pathology, Drs. William G. Bissell, Harvey R. Gaylord and J. A. Miller.

New York City.

The Academy of Medicine is to receive the medical library of the late Dr. Abbott Hodgman, by his will.

A fire at the Eastern District Hospital, Brooklyn, March 8, caused a panic among the patients, but was put out before any injury was done to the inmates.

A practitioner in Brooklyn has been found guilty of filing a false death certificate, in the case of a patient who died from smallpox, and has been fined $100.

The Eye and Ear Hospital has opened its new pavilion for the treatment of communicable diseases. It is the gift of Mrs. Eveline Bliss and her daughters, in memory of the late James N. Platt.

The Bureau of Contagious Diseases reports that smallpox increased in the city during February, 139 cases having been reported. Since November 5, 311 cases have been reported, with 42 deaths.

Library Books and Communicable Diseases.—A resolution has been passed by the Bureau of Health providing that no books shall be loaned from the public libraries to persons affected with contagious diseases. It will be the duty of the assistant medical inspector of the bureau to furnish a list of such patients, and a list will be sent daily to the different public libraries.

OHIO.

Dr. B. B. Taylor, who has been on duty at Columbus Barracks for the past year, has been made captain and assistant surgeon of volunteers.

In Cincinnati, two men have been arrested on the charge of using the prefix "Dr." without having complied with the law requiring registration.

Dr. R. D. Sikes, Newark, has been promoted to medical examiner for the Baltimore and Ohio Railroad Company, and has been *transferred* to Allegheny, Pa.

The Huron Street Hospital, Cleveland, is to be freed from debt. *John D. Rockefeller has promised to pay $5000, if the* balance, $10,000, is secured by October 1. The trustees have already raised $3000 of this amount.

PENNSYLVANIA.

Smallpox is still epidemic at Scenery Hill, whose population is composed mostly of negroes. Up to March 7 21 cases had been reported. A rigid quarantine is being maintained.

Dr. R. L. Taylor, medical inspector of Pittsburg, states that during the year forty-five cases of smallpox were treated at the Municipal Hospital. In his opinion the disease came from twenty different sources. The municipal hospital, it is believed, is inadequate to the needs of the city.

School Directors May Quarantine.—Representative Hamilton, of Jefferson county, has introduced a bill providing that directors of schools in townships, in addition to the powers vested in them, shall also be given the power to prohibit, from attending school, any child or person who resides in a building in which epidemic disease exists. The following are specified: Smallpox, varioloid, scarlet fever, typhoid fever, yellow fever, relapsing fever, diphtheria, etc.

Philadelphia.

Dr. H. C. Wood is in the South, on account of his health.

Jefferson Medical College has asked *an appropriation*, from the legislature, of $300,000 for the establishment of a new hospital, and other improvements.

The deaths from tuberculosis, during the past year, were 2717; from pneumonia, 2915. The mortality from diphtheria was lower than for previous years.

Surgeon H. W. Austin, in command of the national quarantine in the Delaware River and Bay, has been given orders to provide for night inspections of vessels.

Dr. A. H. Cleveland has been elected laryngologist and rhinologist to the Presbyterian Hospital, a department which has only been recently established by the board of trustees.

The University Medical Magazine, with the March number, becomes the *Medical Bulletin of the University of Pennsylvania*. It will hereafter contain no advertising matter and will be somewhat changed in form, the policy of the publication, however, not being altered.

TENNESSEE.

The Greenville Board of Health has raised the quarantine against all smallpox-infected points.

The new building for the Memphis Hospital and Medical College will be started early in April, and is to be ready for occupancy in November.

The Central Hospital for the Insane, Murfreesboro Pike. Nashville, is much overcrowded, and the management has asked for an appropriation of $20,000 for a new building.

Meharry Medical College, Nashville, graduated a class of 40, at its twenty-fifth commencement, February 27. Bishop Walden, of Cincinnati, delivered the address to the graduating class.

TEXAS.

Dr. James A. Sadler, one of the oldest physicians in Sherman, is in a critical condition from cerebral hemorrhage.

Dr. S. E. Hudson, Austin, has severed his connection with the *Texas Medical Journal*. Dr. F. E. Daniel assuming control.

The following appointments to the Medical Examining Board are announced: Dr. Samuel F. King, Sherman; Dr. Stephen A. D. Moore, Van Alstyne, and Dr. Winston B. Markham, Denison.

VERMONT.

Dr. Donly C. Hawley, Burlington, secretary of the State Medical Society for the past fifteen years, and president of the Board of United States Examining Surgeons, for pensions, has been elected mayor of Burlington on the republican ticket.

At the annual meeting of the directors of the Fanny Allen Hospital, Burlington (Winoaski Park), the following staff was elected for the present year: attending surgeons, Drs. W. G. E. Flanders, D. C. Hawley, P. E. McSweeney and O. W. Peck; attending physicians, Drs. A. T. Arkley, Lyman Allen, A. J. St Germain and J. W. Sheehan; consulting surgeons, Drs. L. M. Bingham, Wm. B. Lund, W. R. Prime and J. D. Hanrahan; consulting physicians, Drs. A. P. Grinnell, C. M. Ferrin, W. J. Labelle, H. Pepin and E. A. Burdick; specialist in diseases of eye, ear and throat, Dr. H. E. Lewis; consultant, Dr. Chietien Zaugg; pathologist, Dr. J. H. Linsley.

WISCONSIN.

Dr. Ernest L. Bullard, Waukesha, has been appointed superintendent of the State Hospital for the Insane at Mendota, vice Dr. W. A. Lyman, resigned.

Major John R. McDill, Milwaukee, who went to the Philippines as surgeon of the Thirtieth Volunteer Infantry, and who made so exceptional a record there as to be recommended for promotion by General McArthur, has decided not to return with his regiment, but will remain in Manila and assume control of a private hospital, the first of its kind to be established there.

GENERAL.

Army Dentists.—Dr. John S. Marshall, Chicago, president of the examining board of dental surgeons, U. S. Army, announces that candidates for appointment as dental surgeons in the army will be examined in the following named branches: anatomy, physiology, histology, physics, chemistry, metallurgy, dental anatomy and physiology, dental materia medica and therapeutics, dental pathology and bacteriology, orthodontia, oral surgery, theoretical operative dentistry, theoretical prosthetic dentistry, practical and operative, and practical prosthetic dentistry. An average of 75 per cent. will be required in each subject for theoretical examination, and 85 per cent. in the practical examinations.

Appropriations.—Congress, at its last session, appropriated $35,000 for the erection of the necessary buildings and quarters for a laboratory for the investigation of infectious and contagious diseases, and matters pertaining to the public health, under the direction of the surgeon-general of the U. S. Marine-Hospital Service; and authorized the secretary of the navy to transfer to the secretary of the treasury five acres of the old Naval Observatory grounds, for use as a site for the laboratory. The same bill contained appropriations of $50,000 for a boarding vessel at Reedy Island, Del., and $40,000 for a boarding vessel at Port Townsend, Wash., quarantine stations, and $29,500 for improvements at Delaware breakwater, Cape Fear, Savannah, Columbia River and Reedy Island quarantine stations.

CANADA.

Carberry, Manitoba, is to have a new hospital, erected on the cottage plan.

Dauphin, Manitoba, will erect a modern hospital in the immediate future.

Winnipeg's vital statistics for February were: 110 births, 62 male and 48 female; 71 deaths, 40 male and 31 female; marriages, 39.

The Mount Royal cemetery bill has passed the legislature of the province of Quebec. It provides for the erection of a crematory on the cemetery premises in Montreal, the first of its kind in the Dominion of Canada.

Dr. Wilfrid T. Grenfell, superintendent of the National Mission to Deep-Sea Fishermen, at present in Montreal, established the third hospital in Labrador last summer, and it has accomplished much good in relieving the sufferings of the fisher people.

Winnipeg General Hospital.—The number of patients treated at this institution during the past twelve months was 2649. In the out-door department there were 1435 consultations. Of the indoor patients, 1684 came from Winnipeg, 785 from other places in the province, 150 from the other provinces, and 30 from the United States.

Vaccination Crusade.—Dr. Laberge, Montreal's city health officer, has started a vaccination crusade in order to protect the city from the introduction of smallpox from surrunding centers of infection. He states that the health officials are meeting with less opposition to vaccination in Montreal every year. The old smallpox pavilion contains only four beds, which shows the facilities Montreal has for coping with the disease.

St. John Hospital.—The annual work done at the public hospital, St. John, N. B., last year, shows that 1038 patients were treated, 446 being medical, 486 surgical and 106 eye and ear. The amount expended on hospital maintenance was $28,291.59. The out-door department treated 1102 cases, medical and surgical, and of these 1029 received prescriptions. There were also 412 eye and ear cases, of which 398 received prescriptions.

Neglects Smallpox.—Montreal's civic council is scarcely up to modern hygienic requirements. Recently the secretary of the provincial board of health notified the council that six cases of smallpox were in the outskirts of the city, and suggested that immediate steps be taken to have a temporary isolation hospital improvised. The council showed its appreciation of the urgency of the matter by ordering the communication to lie on the table for a week.

Health Legislation.—The government bill respecting public health has passed its third reading in the Quebec legislature. By it the secretary of the provincial board of health will receive a salary of not more than $2400 per annum; and the board of health may further provide for the appointment of analysts, a statistician and the other necessary officers. There are provisions, too, to the effect that unvaccinated children may be prevented from attending the schools of the province.

Ontario Vital Statistics.—Complete returns have been received regarding births, marriages and deaths occurring in Ontario during 1900. There is an all-round increase, but the most encouraging report is that referring to births, which shows that the birth-rate of the province has increased substantially during the year. This may be accounted for by the fact that there have been a good many prosecutions before magistrates' courts for failure to register births under the provisions of the registration act. The following shows the births, marriages and deaths for the past three years, 1898, 1899 and 1900 respectively: births, 46,599, 44,705, and 46,019, being an increase of 1314 over the previous year; marriages, 15,375, 16,514 and 17,123, an increase of 609; deaths, 26,370, 28,607, and 29,594, an increase of 987. Dr. Bryce, secretary of the Ontario Board of Health, estimates the birth-rate last year at 19.19 per thousand, as compared with 19.4 in 1899 and 20.4 in 1898.

Lodge Practice in British Columbia.—On two or three former occasions notice has been taken in the columns of The Journal with regard to the action of the Victoria Medical Society in refusing to accept lodge practice from the fraternals of that city. The very latest phase of the situation looks as though the medical men were going back on their former laudable resolutions. During the past summer, the special committee on the matter, appointed by the fraternals, has not been by any means idle. Petitions were circulated throughout British Columbia, praying that the medical act of the province be amended to permit of the entrance of the practitioners of the other provinces of the Dominion or practitioners duly qualified from the British Isles, without taking the prescribed examinations of the medical council of the province. So numerous have been these petitions, and so fully have they been signed, that the medical practitioners of Victoria are on the eve of returning to the fraternal fold, and thus renouncing their former worthy and honorable action. Surely the legislature of the province, before whom the petitions now lie, will not permit of such rank coercion.

From the Yukon.—Dawson, as reported in the columns of The Journal recently, is still overrun with mad dogs. The epidemic has assumed alarming proportions and has been so serious as to compel a conference between the police, medical men and leading citizens regarding the best method of dealing with the conditions present. Many persons have been bitten, and the present condition of affairs is a menace to public health and safety. The consensus of the medical opinion is that the disease is undoubtedly rabies, of the type called "dumb rabies." The matter is a serious one from another point of view, a first-class "husky" or "malamite," trained to the sled, being worth from $300 up. Those individuals who have been bitten had their wounds immediately cauterized; but a sense of insecurity and uneasiness prevails among the citizens, as the medical men state that the disease may develop at any time within eighteen months. The citizens are allowed to shoot a dog on sight, when it shows the least evidence of madness; and it is feared that the continuation of the epidemic may cause the extinction of the entire dog species in the Yukon territory. A supply of the Pasteur serum has been ordered.

Consumption Sanatorium for Nova Scotia.—In the legislative assembly of Nova Scotia, last week. Premier Murray laid on the table the report of the special committee appointed by the government to make recommendations in regard to the establishment of a sanatorium for the treatment of the consumptives of the province. The report recommends a single sanatorium, and that the location be either Dutch Village, near Halifax, or on the shore of the Bedford Basin, at or near the village of Bedford. The congregate plan should be adopted for a small number of patients—accommodaton being provided for twenty patients, arranged on the plan of the sanatorium of Dr. Phillips, at Craigleith Hospital, Edinburgh, with a competent and special trained nurse and no medical resident superintendent, but two regular medical men to be appointed to make specified visits every week. The committee expressed the opinion that the treatment of consumptives should be carried on near large centers of population; and that the sanatorium act of the province, enacted at the last session of the legislature, be amended so that it would provide for municipalities receiving government aid for sanatoria, the same as provided for in the Ontario act. Dr. A. P. Reid, secretary of the provincial board of health, endorses the recommendations, but thinks it would be better to have a regular resident medical superintendent. He disapproves also of the Atlantic seabord as not being a suitable site for the purposes of a sanatorium.

FOREIGN.

Among deaths noted abroad are those of Dr. Bawater J. Vernon, F.R.C.S. Eng., January 28. He was a well-known London surgeon of St. Bartholomew's Hospital.

Professor Ostroumoff, of Moscow, retires this year from his connection with the medical faculty, after forty years of service. The students have founded a scholarship in his honor.

The pamphlet, signed by twenty professors, portraying the dangers of venereal diseases, and which is now given to each student at the German universities, has been reprinted by the Bavarian military authorities and distributed among the troops.

Unna's prize for the best work on the histology of primary cutaneous carcinoma was not awarded last year. The amount of the prize is now increased to 600 marks, and the same subject is still open to competition. Articles should be sent to the publisher of his *Monatsschrift*, L. Voss, Hohe Bleichen 34, Hamburg.

Prizes Offered by Belgian Academy.—The Académie Royale de Médecine de Belgique offers a number of prizes open to foreigners. Among them are the following: 800 francs for the best work with new research to determine the relations between the neurons—closed, Jan. 20, 1903; Alvarenga prize of 800 francs for the best work in any branch of medicine, received before January, 1902; anonymous prize of 8000 francs for the best work on pathogenesis and treatment of diseases of the nerve-centers, especially epilepsy—this prize can be divided; 30,000 francs will be added to this prize in case a cure for epilepsy is discovered, or some similar progress is reported.

New Mexican Publication.—The *La Cirurgia Contemporanea* is a new periodical from the City of Mexico. It is the organ of the Mexican Surgical Society, and will be published monthly. It will cover the field of general surgery, gynecology, otology, laryngology, ophthalmology and genito-urinary diseases, and is under the editorial direction of Ramon Macias. The first issue, with its introductory, makes a very favorable impression and contains articles on spinal analgesia, hysterectomy and colostomy, the latter two with illustrations. The editors appear to have broad and liberal ideas as regards the field of medicine which they represent, and the new publication starts out under the most favorable auspices and is likely to be a creditable exponent of Mexican surgery.

Progress of the Plague.—According to cable reports, 15 new cases of bubonic plague were reported in Cape Town, S. A., on March 11, and 97 persons were isolated on account of having been exposed. On the same date two colored persons died in the street, and one European on being removed to the hospital. The affection is extending to the more prosperous classes and the removal of several thousand Kaffirs from the city is being consummated, the government having decided to remove the people from one-third of the city's area and cleanse it. One soldier employed at the castle has been attacked. Since the outbreak there have therefore been 110 cases and 25 deaths. According to the *British Medical Journal* of March 2, 400 died of plague in the City of Bombay on February 24 and 25.

Medical Appointments to the King.—According to *The Lancet*, the king has appointed Lord Lister to be sergeant-surgeon-in-ordinary; Sir William MacCormac, Bart., K.C.V.O., F.R.C.S., and Sir Thomas Smith, Bart., F.R.C.S., to be honorary sergeant-surgeons. Other appointments are—to be honorary physician to the king: Dugald McEwan, M.D.; Sir James J. L. Dennet, K.C.B., M.D., inspector-general of hospitals and fleets; Sir John Watt Reid, K.C.B., M.D., LL.D., director-general of the medical department of the navy (retired); Adam B. Messer, M.D., inspector-general of hospitals and fleets; Henry C. Woods, C.V.O., M.D., inspector-general of hospitals and fleets (extra). To be honorary surgeons to the king: Sir James Jenkins, K.C.B., M.D., inspector-general of hospitals and fleets; Timotheus J. Haran, inspector-general of hospitals and fleets; Sir James N. Dick, K.C.B., director-general of the medical department of the navy (retired); William H. Lloyd, M.D., inspector-general of hospitals and fleets; Alfred G. Delmege, M.V.O., M.D., deputy inspector-general of hospitals and fleets (extra).

LONDON.

Hunterian Oration: Evolution of the Human Skull—Man and Ape.

The Hunterian Oration at the Royal College of Surgeons is usually devoted to a somewhat general description of John Hunter's life and work, and the influence of his example and principles on the growth of surgery. The orator of this year, Mr. Macnamara, the ophthalmic surgeon, instead, selected for his discourse a single biological theme. John Hunter laid the foundataion of the superb museum which, after his death, was purchased by the nation and committed to the care of the college, and which has since been enriched by many benefactions. From its treasures, Mr. Macnamara selected the "unrivalled collection of skulls," and endeavored to show the manner in which this collection throws light upon the sources from which the populations of Europe have been derived. He stated that the numerous characters common to man and the larger apes prove that they had descended from the same stock. The inability of apes to speak he explained by the fact that the anterior portion of their skulls underwent early ossification and this prevented the growth and development of speech centers. In man, on the other hand, this ossification does not take place until the age of 20, and development is possible. In prehistoric times the skull has not this power. The skull found in the tertiary formation in Java is clearly on the boundary line between men and apes, and the human skulls of the pre-glacial and inter-glacial periods more closely resemble those of the chimpanzee than of existing Europeans. With these skulls of low development are found the simplest and roughest implements. After the glacial period the skulls, though of a low type, are still better developed. Europe was then peopled by the Africo-Europeans or Iberians, a short, powerful, long-skulled race.

Mr. Macnamara attributes the better development of the Iberians to the alteration in the climate and fauna of Europe, which compelled them, in the struggle for existence, to make better use of their brains. They were followed by a race of tall people, with large, well-formed skulls, who possessed domestic animals, and used a language which still survives. After them came a tall, broad-skulled Turanian people, then a short, small-boned, broad-skulled Mongolian race. Notwithstanding many changes on the European continent, the distinctive characters of some of these races remain. In the countries which border the Mediterranean, the people are still short, dark and long-skulled (Iberians. North Germany and Scandinavia contain a large proportion of the tall, fair, long-skulled Teutonic race (Aryan), while a vast triangle, with its apex in central France and its base in eastern Russia, is inhabited by the descendants of the broad-skulled Turanian and Mongolian races.

Extraordinary Fraud—A Man Obtains His Own Death Certificate.

A man aged 35, described as a Dublin medical student, came to lodge in London and called on a doctor, minutely describing to him the symptoms of Bright's disease. He also brought urine for analysis, and it contained a large quantity of albumin. One day, when the doctor called, he appeared to be very drowsy and dangerously ill. Early on the following morning a man resembling the patient called on the doctor, but he was clean shaven and in good health, while the patient had a heavy moustache. The visitor posed as the brother of the patient, who, he said, had passed away in great suffering during the night. He was given a certificate of death. In pursuance of his usual practice the doctor visited the chamber of death. In the dimly-lighted room what appeared to be a human body was perceptable on the bed, but on examination the "corpse" proved to be a dummy composed of pillows, blankets, boots and a poker. The man who obtained the certificate, on being questioned, said: "I am the dead body," and asserted that he had committed the deception to deceive his people into the belief that he was dead. A search in his box, however, showed that he had a life policy of $1000. For having made a false declaration for the purposes of death registration, he has been sentenced to nine months' imprisonment. It appears that the man was really ill and had a high temperature, but simulated the special symptoms of Bright's disease.

Eclipse Blindness with Thrombosis of the Retinal Artery —Hemorrhage into the Vitreous.

At the Ophthalmological Society, Dr. R. D. Batten has reported the case of a woman aged 28, who watched the eclipse on May 28, 1900, without other protection than "screwing up the eyes" and looking between her fingers held close together. Objects immediately appeared black, anl, next morning, she could see only "portions of things." On June 6, when she was first seen, she had lost the lower half of the field of vision in the left eye, V = 6/18. Above the disc was a white patch, possibly an absorbing hemorrhage, and the hazy edematous retina obscured the view of the disc and retinal vessels. The edema increased until June 20, and then rapidly cleared, leaving a patch of choroidoretinitis above the disc. One of the upper-retinal arteries was occluded and the others were reduced in size. The vitreous opacities cleared and the macula was unaffected. V. improved in the injured eye to 6/12. In the right it was 6/6.

Mr. Lawford said that he had observed three cases of eclipse blindness, but without ophthalmoscopic signs. In all, however, the scotomata had persisted with deterioation of vision. Mr. Jessop had jublished three cases. In all, vision improved, but there was a slight permanent scotoma. Mr. Bokenham gave details of two cases, in one of which there were retinal hemorrhages. V. improved from 5/60 to 6/12, but there was a marked central scotoma. Dr. G. A. Berry thinks the scotoma is usually permanent in the worst cases. The public is not aware that blue glasses are worse than useless in looking at the sun and bright lights. It is the blue and violet rays which do damage. In Russia, red or yellow glasses are employed.

Correspondence.

Port Limon and Yellow Fever Reports.

Treasury Department, Office of the Supervising Surgeon-General, Marine-Hospital Service, Washington, D. C.,
March 8, 1901.

To the Editor:—In The Journal of March 2, under "Correspondence," is a letter from Dr. Edmond Souchon, president of the Louisiana State Board of Health, which takes exception to some of the suggestions contained in a paper by Dr. Nicholas Senn, published in The Journal of January 19. Dr. Souchon quotes Dr. Senn's suggestion of placing the port of New Orleans under the jurisdiction of the U. S. Marine-Hospital Service, etc., and makes the following statement: "This expression is most unfortunate, especially as coming so soon after the signal failure of the Marine-Hospital Service to recognize the existence of yellow fever in time at Port Limon last year. That service admitted the existence of the fever there several weeks only after the distinguished representative of the Louisiana State Board of Health, Dr. Will H. Woods, had advised the board of the presence of the fever at Limon, and after cases had occurred on fruit vessels plying between that port, New Orleans and Mobile. Mobile was guided by the reports of the representative of the U. S. Marine-Hospital Service and escaped infection only by enforcing the most rigid measures. Although Mobile had not actually recognized Limon as infected, she treated vessels from there as if the port was infected. Finally she did proclaim Limon infected."

In refuting Dr. Souchon's statements, I think it necessary to first disavow any inspiration either from myself or, so far as I know, from any officer of the Service, prompting Dr. Senn in his expression of opinion, but I can not allow Dr. Souchon's statements to go unquestioned.

So far from the signal failure of the U. S. Marine-Hospital Service to recognize the yellow fever in time at Port Limon last year and only admitting its existence there several weeks after Dr. Woods had advised the Louisiana State Board of Health of its presence, I have to state that the advice of Dr. Woods, as referred to, was about the middle of July, whereas by reference to the *Public Health Reports* of May 4, 1900, page 1072, it will be seen that Acting Assistant Surgeon Thomas, of the Marine-Hospital Service, cabled from Port Limon as early as April 20 the existence of one fatal case of yellow fever in that port. Moreover, as early as April 20—see *Public Health Reports* of that date—a report from Acting Assistant Surgeon Hodgson, specially detailed to obtain information concerning Central American ports, was published bearing date of April 7, in which he states as follows: "Port Limon, Costa Rica, is the cleanest town south of the Rio Grande on the seacoast, but I consider it the most dangerous. I think that yellow fever is endemic in the port." etc.

Dr. Souchon's letter would leave the impression that no notice of the condition of this port was given until his own officer advised the Board of the fever at Limon in July, and it is to relieve this impression that I quote the above publications. Now, so far as the report of Dr. Woods referred to is concerned, the Service never has and does not yet admit its correctness, but to be entirely on the safe side the bureau published a cable from Acting Assistant Surgeon Thomas, dated July 17 and published in the *Public Health Reports* of July 27, as follows: "Woods reports to State Board Health, New Orleans, La., 1 case yellow fever, 1 suspicious. Drs. Carson, Steggall, Aguilar and myself disagree with Woods," and in *Public Health Reports* of August 3, under date of July 19, Dr. Thomas explains at length his reasons for disagreeing.

It is understood that Dr. Woods, after reporting this case as yellow fever, reported to his board four other cases as yellow fever, all of which were seen by three of the consultants in the first case, by whom they were not even regarded as suspicious. No official reports of these as yellow fever cases have ever been received at this Bureau, but the charts and the statement from Acting Assistant Surgeon Thomas showing them to be malaria are on file.

August 18 and 22, cases of yellow fever which occurred on vessels were reported by Acting Assistant Surgeon Thomas. (See *Public Health Reports*, August 31, p. 2164, and September 7, p. 2276). On October 31 another case occurred on a vessel and was duly reported by Acting Assistant Surgeon Thomas over the cable. (See *Public Health Reports*, Nov. 30, 1900, p. 2929). On October 31 there was one case of yellow fever reported in Port Limon, which was duly cabled.

It is true that Mobile was guided by the reports of the Marine-Hospital Service, but as to enforcing most rigid measures they were no more than are ordinarily enforced under like circumstances.

I deem the above statements necessary simply to show the watchfulness and care of the Marine-Hospital Service at Port Limon last season.

To summarize, in April, a representative of the Service made a full report on the sanitary conditions of Port Limon. On April 20 a case of yellow fever was reported by the acting assistant surgeon stationed there. July 17 a suspicious case, with the full facts, was reported by the acting assistant surgeon, who, however, denied, together with three other prominent physicians, the diagnosis of Dr. Woods, who stood alone in his belief. The remaining cases of yellow fever that occurred at Port Limon, four in number, were duly reported as soon as they occurred.

All the above facts were published. Respectfully,

Walter Wyman, M.D.
Surgeon General, M.-H. S.

Committee on National Legislation and Annual Conference, Washington, D.C.

To the Editor:—By an amendment to the quarantine laws, the last Congress authorized the Surgeon-General of the U. S. Marine-Hospital Service, with the approval of the U. S. Secretary of the Treasury, to designate and mark out the boundaries of the quarantine grounds and anchorages for vessels at the United States quarantine stations, and imposed a penalty of fine or imprisonment or both for the violation of any part of the act or any regulation made in accordance with the act.

Another section of the amendment provided for quarantine measures to apply to vessels arriving in collection districts without entering a port of the United States. This is intended particularly for fishing-smacks and other small craft which leave Cuban ports for smuggling rum and tobacco into the United States along the coast of Florida; these vessels were liable to convey infection by landing their sick on this coast.

To further aid in the enforcement of the quarantine laws the act gave authority to national quarantine officers to administer oaths.

The above law was recommended by the Committee on National Legislation of the American Medical Association, and approved, at their annual conference, held at Washington, D.C., Feb. 20 and 21, 1901, of the legislative delegates from the various states of the United States. Concerted action in the future will, it is hoped, secure more legislation indorsed or proposed by the national conference with the legislative committees of the American Medical Association.

H. L. E. Johnson, M.D.

Chairman Committee on National Legislation, American Medical Association.

Quarantine Against Plague.

New York, March 8, 1901.

To the Editor:—Dr. Doty is quoted by Dr. Bracken, in The Journal of March 9, p. 677, as having said that "rats collected at New York, from coffee-carrying vessels from Rio Janeiro and Santos, during the recent outbreak of plague in those two places, were examined bacteriologically, and in no instance was there the slightest evidence of bubonic plague." I add that neither did Dr. Doty's bacteriological examination disclose bubonic plague in the body of the dead laborer on one of the lighters to which the cargo was being removed in mid-bay—who suddenly died of pneumonia. Yet the man's hands had been in direct contact with the rat-infected cargo, and had breathed into his lungs its dust. Credit is due President Murphy, of the New York Board of Health, for his firmness in not permitting the port quarantine service to unload those ships at their piers. Had that been done, some sick rats could have come ashore to infect our sewers by their droppings, or by transferring their infected fleas to our rats. And this plague pneumonia, if the bubonic stage was delayed, might have gained its foothold here. The Bombay Medical Union claimed that in some such way their city became infected from sugar cargoes from Hongkong, which were unloaded at the granary-piers, the feeding places of the Bombay rat.

Dr. Doty's position, at the time of our controversy, was wholly on the side of the coffee importers and the New York Chamber of Commerce. Albert S. Ashmead, M.D.

Washington's Governor and Medical Practice.

Spokane, Wash., March 4, 1901.

To the Editor:—I noted with great pleasure your very just criticisms on the conduct of Governor Thomas of Colorado, in a recent issue of The Journal, also the manner in which the profession has turned him down. I take pleasure in informing you that our state legislature has similarly rebuked John R. Rogers, the present governor of the State of Washington.

At the beginning of the present session of our legislature one of the representatives from this county, Dr. C. G. Brown, introduced a bill which was a slight improvement over our former medical act, in that it prevented osteopaths and other quacks from practicing without having been properly licensed. It also made possible conviction of parties practicing medicine without the necessity of proving that they actually received money for the services. In addition to this, it has a provision for recognizing the licensed graduates from other states, having regular licensing bodies. This bill, after passing both houses, was vetoed by the governor in a long harangue on the blessings of osteopathy, which was published in all the papers in the state. The bill was immediately reconsidered, through the efforts of Dr. Brown, and has now passed both houses with a safe majority, and is a law. Yours very respectfully,

C. P. Thomas, M.D.

[The Journal of March 9 editorially commented on this action of Washington's governor, the news of the above reprimand to his veto having been received after that issue of The Journal was on the press. Ed.]

Subscriptions for Ollier Monument.

To the Editor:—The undersigned constitute a committee similar to those formed in several European countries for the purpose of receiving subscriptions for a monument commemorative of the distinguished scientific services of Prof. Leopold Ollier. Among the members of these committees are Lord Lister, Professors von Bergmann, Czerny, Durante and other leading men. The municipality of the city of Lyons has dedicated an open space adjacent to quarters of the various academic faculties on the border of the Rhone, named in his honor "Place Leopold Ollier."

The profession of this country is well aware of the great services rendered by Professor Ollier, especially in the domain of plastic and osseous surgery. His labors have been most fruitful in the domains of surgery, of physiology and pathology.

The committee hopes to raise not less than $1000 as a testimonial from the profession of America. Check should be forwarded to Dr. W. W. Keen, 1729 Chestnut street, Philadelphia, at as early a date as possible.

Committee:—Robert Abbe and William T. Bull, New York; P. S. Conner, Cincinnati, Ohio; A. T. Cabot, Boston; Howard A. Kelly, Baltimore; W. W. Keen, Philadelphia, Rudolph Matas, New Orleans; Wm. J. Mayo, Rochester, Minn.; W. F. McNutt, San Francisco; Roswell Park, Buffalo, N. Y.; Clayton Parkhill, Denver, Colo.; Maurice H. Richardson, Boston; Nicholas Senn, Chicago.

Married.

George A. Broughton, M.D., Oxnard, Cal., to Miss Mary Livingston, of San Francisco, Cal.

William A. Caven, M.D., Hazelwood, Pittsburg, Pa., to Miss Margaret Elizabeth Wirchack, of Monessen, Pa., February 28.

George W. McCoy, M.D., U. S. M.-H. Service, formerly of Bristol, now stationed in San Francisco, Cal., to Miss Edith Miller, of Pennsylvania, at San Francisco.

Deaths and Obituaries.

Richard J. Dunglison, M.D.

Dr. Richard James Dunglison died at his home in Philadelphia, March 5, from dropsy and heart failure, following an attack of pneumonia a year ago. He was born in Baltimore, Nov. 13, 1834, and came of a medical family, his father being Dr. Robley Dunglison, professor of institutes of medicine and medical jurisprudence in Jefferson Medical College, and his grandfather, Mr. John Leadam, a noted surgeon of London, England. He was graduated from Jefferson Medical College in 1856, but after a few years relinquished the practice of medicine for the field of medical literature. He was editor of two editions of "Dunglison's Medical Dictionary," and of the "History of Medicine," of which his father was the author; was editor of *Dunglison's College and Clinical Record* for fifteen years, one of the original editors of the *Philadelphia Medical Times*, for several years Philadelphia correspondent of the *Medical Times and Gazette* of London, and a frequent contributor to the medical literature. He was the author of the "Practitioners' Reference Book;" "A Handbook of Diagnosis, Therapeutics and Dietetics"; "A New School of Physiology and Hygiene"; "An Elementary Physiology and Hygiene," and "The Present Treatment of Diseases." He also translated Guersant's "Surgical

Diseases of Children," from the French. From 1862 to 1865 he served as acting assistant surgeon in the United States Army, in various military hospitals in Philadelphia, for the last two years of that time being executive officer of the Filbert Street Hospital. He was a member—and for many years treasurer—of the Philadelphia County Medical Society; and of the College of Physicians of Philadelphia; a member and, in 1875, corresponding secretary of the Pennsylvania State Medical Society; of the American Academy of Medicine, of which he was secretary and treasurer for several years and vice-president in 1890. He was for many years a member of the AMERICAN MEDICAL ASSOCIATION, of which he was assistant secretary in 1876, and treasurer from 1877 to 1894. He was also assistant secretary of the International Medical Congress in 1876, and corresponding secretary of the Centennial Medical Commission in the same year. In 1877 he served as secretary of the executive committee and chairman of the finance committee of the Ninth International Medical Congress. He was also corresponding secretary of the Alumni Association of Jefferson Medical College from its inception, and for many years honorary local secretary of the New Sydenham Society of London.

John Dean Ross, M.D., University of Pennsylvania, 1832, died at his home in Williamsburg, March 5, aged 95. He founded the Blair County Medical Society in 1848, and was the first president. He was president of the State Medical Society in 1865, and at the time of his death was its oldest member. He had been a member of THE AMERICAN MEDICAL ASSOCIATION for forty-seven years.

Charles F. Knight, M.D., Medical School of the Valley of Virginia, Winchester, 1852, one of the pioneer physicians of Missouri, formerly superintendent of State Asylum No. 2 for the Insane, one of the founders and the first president of the St. Joseph, now the Ensworth Medical College, died March 4, at his residence in St. Joseph, after a lingering illness, aged 71.

J. Stone Armstrong, M.D., Jefferson Medical College, Philadelphia, 1879, a prominent physician of Buffalo, and at one time grand master workman of the A. O. U. W. of New York State, died at his home, March 4, from pneumonia, after a short illness, aged 61.

R. Wilson Carr, M.D., University of Maryland, Baltimore, 1852, a member of the Walker expedition to Nicaragua, a surgeon in the Confederate Army, and for a quarter of a century a resident of Sedalia, Mo., died at his home in that city, March 5, aged 70.

George Holmes Bixby, M.D., Harvard Medical School, for many years a gynecologist in Boston and a frequent contributor to the literature of that specialty, died at his home in Boston, February 26, after many years of invalidism, aged 63.

James Chapman, M. D., New York University, 1852, for many years a surgeon in Medina, N. Y., and in the Civil War, died from paralysis, after an illness of several years, at his home in Medina, February 27, aged 77.

Thomas H. Morrow, M.D., Northwestern Ohio Medical College, Toledo, 1889, of Erie, Mich., while driving across the tracks in Toledo, Ohio, February 27, was killed by a train.

Aloysius X. Whiteford, M.D., Washington University School of Medicine, Baltimore, 1873, died at Parkville, near Baltimore, February 28, after a lingering illness, aged 52.

Lawrence J. McDonough, M.D., University of Vermont, Burlington, 1886, died at St. John's Hospital, Lowell, Mass., after an illness of three months, March 2, aged 45.

S. A. Mercer Given, M.D., University of Pennsylvania, 1887, Clifton, Pa., died at that place, February 23, aged 41, from diabetes, after a long illness.

Fred L. Thayer, M.D., Harvard Medical School, 1871, died after a long illness, from Bright's disease, at his home in West Newton, Mass., aged 53.

Frederick Hibbard, M.D., Medical College of Ohio, Cincinnati, 1884, died suddenly at his home in Little Hocking, Ohio, February 23, aged 40.

James C. Smiley, M.D., who had practiced in Kewanee, Ill., for more than thirty-five years, died at his home in that town, March 3, aged 70.

Tillie Dittenhoefer, M.D., University of Oregon, 1896, died suddenly from heart disease, February 22, aged 40, in Portland, Ore.

Alpheus J. Clemmons, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1879, died at St. Joseph, Mo., March 8.

William G. M. Seiple, M.D., University of Pennsylvania, 1867, died at his home in Lehighton, Pa., March 1, aged 55.

William B. Young, M.D., Jefferson Medical College, Philadelphia, 1845, died at his home in Higley, Fla., February 22.

Robert Stone, M.D., College of Physicians and Surgeons, New York, 1858, died in New York City, March 7.

Book Notices.

MASTERS OF MEDICINE. THOMAS SYDENHAM by John Frank Payne, M.D., Oxon. Fellow and Harveian Librarian of the Royal College of Physicians. Cloth. Pp. 264. Price, $1.25. New York: Longmans, Green & Co. 1900.

The life of Sydenham is not "an open book," and the paucity of material referring to the man and his work makes a satisfactory biography out of the question. The author has placed before the reader all that is known of the "great physician," but no attempt is made to fill in gaps which reliable records have left. To those who had formed a high opinion of Sydenham, without inquiring why he has been placed on the pedestal he seems to occupy in British medicine, the reading of this book will be a disappointment. Not that the author has not done his work well, for he has, but the records do not appear to show that Sydenham was such a remarkable man. If asked what Thomas Sydenham had done that he should be regarded so highly, few would be able to give a satisfactory answer. He is supposed to have first described that form of chorea which still bears his name, but his biographer quotes Sturges as saying that Sydenham's original description of it was so imperfect that the disease could hardly be recognized therefrom, and the biographer confesses that "it is not a very complete picture of the disease." He introduced a liquid form of opium, a preparation similar to wine of opium of later time, called "Sydenham's laudanum," and which appeared in books, under this name, till quite recently. The biographer credits this with making its originator more widely known than did his writing. His books do not show any great amount of wisdom, nor did they have any material effect on the practice of the time.

The book, however, is not only an interesting, but is also a valuable one in that it depicts the profession as it was then. It shows that quackery was just as influential at that time as it is now; and there is some satisfaction in knowing that, in this regard at least, we are no worse off than was Sydenham and his fellows.

PARALYTIC DEFORMITIES OF THE LOWER EXTREMITIES. The Principles of their Surgical Treatment. By E. Noble Smith, F.R.C.S. Edin., L.R.C.P. Lond., etc., Senior Surgeon to the City Orthopedic Hospital, and Surgeon to All Saints' Children's Hospital, London. With 51 Illustrations. Cloth. Pp. 99. Price 5 shillings. London: Smith, Elder & Co. 1900.

This little work is a general review of the aspects of paralytic deformities of the lower extremities, with especial consideration of the question of functional treatment. While brief, the work is a valuable addition to orthopedic surgery. It is fairly well illustrated.

OBSTETRIC CLINIC. By Denslow Lewis, Ph.C., M.D., Professor of Gynecology in the Chicago Policlinic. A series of Clinical Lectures on Practical Obstetrics delivered to Students and Practitioners in Cook County Hospital, Chicago, together with Remarks on Criminal Abortion, Infanticide, Illegitimacy, the Restriction of Venereal Diseases, the Regulation of Prostitution and other Medico-Sociologic Subjects. Cloth. Pp. 640. Price $3.00. Chicago: E. H. Colegrove. 1900.

Dr. Denslow Lewis has reproduced, in book form, the clinical lectures given by him in 1887 in the Cook County Hospital, Chicago. These include the majority of the subjects included under the general head of obstetric practice, and also some sociologic papers which do not necessarily fall under the head of clinical lectures. Dr. Lewis is an able lecturer and knows how to present the cases in an interesting and edifying manner, and his lectures will be profitable reading. The student and practitioner both will find the perusal of this work instructive. We wish we could say as much in favor of the make-up of the book which is defective in several ways. The paper is of inferior quality and the changes of tints are almost trying to the eyes. It is a pity that such a meritorious volume in many respects is not better presented to the public.

Ethical Marriage. A Discussion of the Relations of Sex from the Standpoint of Social Duty. By Delos F. Wilcox, Ph.D. Cloth. Pp. 235. Price $1.25. Ann Arbor, Mich.: Wood-Allen Publishing Co. 1900.

Ethical marriage, the author says, is a protest against the idea that the matter is to be discussed by physicians alone. This is, therefore, a popular presentation, including certain subjects which are not commonly said to be suitable for general discussion. The author's treatment is commendable in some respects, and in others open to objection. We can not say that we think the book as a whole one to be recommended to the young, notwithstanding the excellent moral tone of many of its chapters. It is a curious fact that the author idealizes a writer who is not, in the opinion of many who have glanced over his works, the most moral in his tendencies, and for that reason we should have some suspicion of his judgment on these matters. The book is well written and doubtless will be found readable, but we do not think it as good a work as some others that have been issued under the same apparent auspices.

Physical Diagnosis in Obstetrics. By Edward A. Ayers, M.D., Professor of Obstetrics in the New York Polyclinic. With Illustrations. Cloth. Pp. 276. Price $2.00. New York: E. B. Treat & Co. 1901.

This work is meant to serve as a guide to physicians and undergraduates in the examination of pregnant, parturient and puerperal women. It is, indeed, an elaborated case-taking chart, emphasizing all important points to which attention should be directed in the study of clinical obstetrics. In the training of medical students, in most schools of America, less care is given to practical and bedside obstetrical teaching than to any other branch of medicine. The facilities for the imparting of thorough instruction are scanty, and teaching methods are crude and undeveloped. Dr. Ayers has done good service in showing how much can be done by a competent and conscientious teacher who desires to give his students something besides systematic didactic lectures. It is a pity that the book is not printed in better style. Most of the illustrations are badly reproduced and several qualities of paper are used. The work is in no way creditable to the publishers.

Clippings from Lay Exchanges.

RARE SURGICAL OPERATION.

New York, March 7.—"A clerk in an insurance company is in St. Luke's Hospital, recovering from a surgical operation, one of the rarest known to medical science. The operation is known as gastro-anterostomy, and consists of removing the patient's stomach, cutting away several malignant growths in the vicinity of the pyloris and restoring the stomach to its former place." The patient "complained some months ago of severe pains in his stomach and was troubled with insomnia. . . . a tube inserted. . . . showed a total disappearance of all acids and a destruction of the pepsin. . . . Examination disclosed a systematic degeneration of the pancreas. . . . The stomach was cut away from the intestines and the organ was lifted completely out of its place and laid on a cushion of antiseptic clothes placed on the patient's chest. The stomach was then put back in its accustomed place. . . . But little blood was apparent throughout the whole operation. . . . The patient rallied at once and it was seen that the operation was a success."—*Evening Post*, Chicago, March 7, 1901.

MURPHY BUTTON EXPLAINED.

"A tube was inserted in Mr. ——'s abdomen leading into the intestines. . . . This tube is closed with a Murphy button, so called from having been invented to suit the case of Colonel Michael C. Murphy, the police commissioner.—*New York Tribune*, March 8, 1901.

ONE OF FORTY.

"One of the oldest and wealthiest residents of this section (Sioux City, Iowa) submitted to a delicate operation yesterday. His malady is one of the rarest in the world, less than forty other similar cases having ever come to the notice of medical men. It is called eurthro millilagia, which causes the blood to coagulate and refuse to go back to the heart. The pressure caused by the active blood against the stagnant portion causes great pain in the parts affected. . . . The operation consisted in cutting nerves controlling veins near the instep. . . A French physician published a book in two volumes in which eurthro maliligia is exhaustively treated of and a remedy suggested. The patient sent for the books, had them translated, and has undergone the operation on the suggestion of the French specialist."—*St. Paul* (Minn.) *Dispatch*.

HOW HE SETTLED THE BILL.

"A well-known physician recently sent to the address of one of his patients a bill for professional services, and within ten days received the following letter written on the back of his memorandum: 'Dear Sur: This note was put in my box by mistake. I han't the man hee's dead and aint no relation of mine anyway. I don't see how your conshens will let you dun the dead. Why don't you live a better criston life and let live and try to meat that man who dide in heaven which is worth moar than forty dollars to enny doctor."—*Ft. Smith* (Ark.) *Elevator*, March 1, 1901.

"BONIFIED" OSTEOPATHY.

"William Hartford, a graduate under Andrew T. Still, the founder of Osteopathy, has located. . . . at Champaign, Ill. He does not pretend as having graduated from the great colleges in Europe and America, for such a thing is disgusting to an honest and meaning people, but he does claim that he is the only bonified osteopathist in Champaign county and is perfectly willing to substantiate what he says."—*Farmer City* (Ill.) *Sun*.

MEDICAL JURISPRUDENCE.

"The condition of Judge —— at the present time is more serious than at any time since the beginning of his recent sickness. . . . His son, Dr. ——, of Chicago, assisted by the local physician, is in constant attendance and everything known to the medical jurisprudence is being done to prolong his life and alleviate his suffering."—*Council Bluffs* (Iowa) *Nonpareil*, Feb. 26, 1901.

LADY ASSISTANT NEEDED.

"Dr. —— returned Monday evening. . . . He was called to Blue Earth to treat several cases of appendicitis, among them some ladies which rendered it necessary for him to take his lady assistant."—*Fond du Lac* (Wis.) *Commonwealth*.

A VALUABLE COMBINATION.

"L. L. ——, the undertaker, has just completed a course at the San Francisco College of Physicians and Surgeons, and passed his examination with 97 per cent."—*Oakland* (Cal.) *Tribune*.

GASTRIC AND STOMACH TROUBLE.

"A lady in Hedding, N. H. . . . says the after-effect of the grip was a serious gastric and stomach trouble."—*Chicago Times-Herald*, Jan. 12, 1901 (Adv.)

THE NEW SURGEON-GENERAL.

"Dr. —— left last month for San Francisco where he was appointed surgeon-general in the United States Army."—*Lawrence* (Mass.) *Telegram*.

MEDICAL SURGEON.

"Joe B.——, the medical surgeon, of Logansville, has moved to Crayon."—*Urbana* (Ohio) *News*.

APPENDICITIS.

"Dr. Swaney took another attack of Appendicitis a few days ago."—*Youngstown* (Ohio) *Telegram*.

Miscellany.

The Population of Germany.—According to the census of Dec. 1, 1900, as announced by the official organs of the empire, this is 56,345.014, of which 27,731,067 are males. Thirty-three of the largest towns aggregate 9,108,814. Since 1895 the population has run up to 7.78 per cent., the highest rate for any quinquennial period for the last thirty years.

Influence of Extract of Feces on the Blood.—Dogs and rabbits were injected subcutaneously with various extracts of fecal substances. The aqueous extract produced a marked effect on the composition of the blood, diminishing the number of red corpuscles and the amount of hemoglobin, with pronounced anemia in various organs, the animals dying of pernicious anemia. The experiments are reviewed in the *St. Petersburg. Med. Woch.*, No. 4; the results suggest an explanation of the etiology of idiopathic pernicious anemia in man.

Total Excision of Larynx.—A case of total excision of the larynx is reported in the *Medical Press and Circular* of February 16, in a man of 55, for carcinoma. The larynx was removed under complete narcosis, without previous tracheotomy. and a canula being employed only after the operation was finished. The patient wears an artificial larynx, by means of which he speaks quite intelligibly and so that he can be heard over a large room. The malignant growth occupied the whole left half of the larynx and anteriorly extended through the midline to the right hand, extending downward to the cricoid cartilage.

The Commission Evil.—The following is taken from the *Texas Med. Gaz.* for February: "We append a clipping from the *New England Medical Monthly* concerning the payment of commissions on cases referred to the surgical or other specialist by the general practitioner. There has never been a question of ethics or morality before the profession that had as little to recommend it to decent men as this so-called commission evil. The discussion of it needed only to be carried to its logical conclusion to show that, as far as his relation to the patient is concerned, there is no honorable ground left for either the man who tenders the fee or the one who accepts it. It is gratifying to see that the profession at large, whose common sense can usually be relied upon, has come to this conclusion and we will hear much less of it, in the future, than in the past. The article is written from the standpoint of 'a member of a medical society, in which the president, vice-president, secretary and various committees are all comprised in one man,' in other words, the writer himself: 'Speaking of confidence in each other brings us to another comment in our local society transactions. We view with great alarm the entrance of a commercial spirit in parts of the profession, and the birth of a son of the commercial spirit in the form of the commission evil. That would promptly destroy whatever confidence the people have in our profession as a whole, and it woud undermine the very pillars and foundation of responsible medical service. There are men in the profession whom our local society holds in reverence, and we often refer cases to them for special treatment that is better than any that we can give the patients who have put their trust in us. If one of these men were to offer us a commission for referred cases he would promptly fall from his pedestal before our very eyes, and become a statue of Achilles with his head in the mud. We are engaged in special work ourselves. We have not often been asked to give any commissions and, as a local society, we pride ourselves in the belief that certain men gave one good look at us and then did not dare to ask it. There is a homely old saying about birds of a feather having a fondness for getting close to each other, and our society believes that the commission birds will soon be distinguished as a class by that responsible element in society which knows pretty well the character of its legal, clerical and medical advisers. We believe that the giver and receiver of medical commissions will carry in their countenances the little cloud of dishonor that recognized by one's self is recognized by others.'"

Societies.

COMING MEETINGS.

Medical Society of the Missouri Valley, Omaha, Neb., March 21, 1901.

Tri-State Medical Society of Iowa, Illinois and Missouri, Keokuk, Ia., April 2-3, 1901.

Medical Association of the District of Columbia, Washington, D. C., April 2, 1901.

Tennessee State Medical Society, Nashville, April 9-11, 1901.

Florida Medical Association, Jacksonville, April 10, 1901.

Western Ophthalmological and Otolaryngological Association, Cincinnati, Ohio, April 11-12, 1901.

Medical Association of the State of Alabama, Selma, April 16, 1901.

Medical Society of the State of California, Sacramento, April 16-18, 1901.

South Carolina Medical Association, Florence, April 17, 1901.

Medical Association of Georgia, Augusta, April 17, 1901.

Louisiana State Medical Society, New Orleans, April 18-20, 1901.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 23-26, 1901.

Texas State Medical Association, Galveston, April 23, 1901.

American Association of Genito-Urinary Surgeons, Old Point Comfort, April 30, 1901.

Association of American Physicians, Washington, D. C., April 30, 1901.

Austin Flint Medical Society.—This Society recently held its tenth annual banquet at Pittsburg. About twenty members were present. Dr. Joseph Stein acted as toast-master.

International Congress of Physiology.—The fifth session of this Congress will be held at Turin, September 16 to 19, in Professor Mosso's Institute. The secretary is Dr. Treves, Corso Raffaelo, 30, Turin, Italy.

Tri-State Society of Iowa, Illinois and Missouri.—The ninth annual meeting of this Society will be held at Keokuk, Iowa, April 2 and 3. Dr. Henry Hatch, Quincy, Ill., is president, and Dr. William B. LaForce, Ottumwa, Iowa, secretary.

French Congress of Surgery.—The subjects announced for discussion at this Congress, which will meet in Paris, October 21 to 26, are "Surgery of the Spleen" and "Treatment of Tubercular Lymphadenitis," with addresses by Février and Broca.

Louisville (Ky.) Society of Medicine.—At a meeting of this Society, March 4, the following officers were elected: Dr. Richard T. Yoe, president; Dr. William A. Jenkins, vice-president; Dr. Waller O. Green, secretary, and Dr. A. Henry Falconer, treasurer.

Ingham County (Mich.) Medical Association.—The physicians of Ingham County met at Lansing for organization, March 1, and elected Dr. Frank W. Shumway, Williamstown, temporary president, and Dr. Alexander D. Hagadorn, Lansing, temporary secretary.

Tippecanoe County (Ind.) Medical Society.—The annual meeting of this Society was held in Lafayette, March 4. Dr. Milton S. Hopper was elected president; Dr. Franklin B. Thompson, vice-president; Dr. John S. Morrison, secretary, and Dr. George K. Throckmorton, treasurer—all of Lafayette.

Medical Society of the Missouri Valley.—The thirteenth semi-annual meeting of this Society will be held at the Paxton Hotel, Omaha, Neb., March 21. Dr. Vernon L. Treynor, Council Bluffs, Iowa, is president, and Dr. Chas. Wood Fassett, St. Joseph, Mo., secretary.

Madison County (Ala.) Medical Society.—At a recent meeting at Huntsville, this Society endorsed the bill restricting child labor in factories, and adopted a resolution asking the representatives in the legislature to support a bill for compulsory vaccination in the state.

French Congress of Neurology.—The neurologists and alienists of France hold their congress this year, at Limoges, in August. The subjects announced for discussion are the "Physiology of the Muscle Tonus, and Modifications of the Reflexes in Case of Lesions of the Cerebrospinal Axis"; "Acute Delirium" and "Attendants in Asylums," to be presented by Crocq, Carrier and Taguet.

Laennec Society, Baltimore.—At the last meeting of this Society, Dr. W. S. Thayer read a memoir on Laennec, and Dr. Louis Hamburger spoke on "The Physical Signs of Pulmonary Tuberculosis as Described by Laennec." He exhibited a model of the first stethoscope made by Laennec. It was twelve inches long, and a nearly solid tube with a small central canal. One end was hollowed out to contain a stopper for use in auscultating. The instrument was formed of two equal halves fitting onto each other for greater convenience in carrying. Laennec made his own stethoscopes and did not bare the chest in examinations. At the same meeting Dr. Sowers read a paper on "The Growth of Our Knowledge of Acute Miliary Tuberculosis."

Orleans Parish (La.) Medical Society.—At a meeting of this Society, recently, in New Orleans, Dr. Louis G. Le beuf reported the case of a puerpera who died on the fourteenth day from cardiac embolism, having given no previous signs other than unrest and a vague premonition of death. Dr. William Scheppegrell presented an article on "Dust as a Factor in Diseases of the Upper Respiratory Passages." As a result of the discussion on this paper it was resolved to take steps to secure the passage, by the city council, of a strict ordinance against spitting in public places. In response to an appeal from Dr. Rudolph Matas, of the American Committee on the Ollier Monument, the Society voted $25 for the fund to erect, in Lyons, a monument to this great French surgeon. A special committee was appointed to study the mosquito as a means of propagating yellow fever

---

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting held February 27.

Dr. George Erety Shoemaker in the chair.

Typhoid with Unusual Temperature.

Dr. Elizabeth Peck reported two cases of typhoid fever. The first was in a woman 32 years of age, and in whom nervousness was a pronounced symptom. What was striking in this case was the excessively high temperature, which often rose to 109 F., probably due to hysteria. The temperature was taken by several thermometers, simultaneously in the mouth, axilla, and rectum. It was observed that at times the temperature in one region would be higher than the others, and would alternate. The patient made an uneventful recovery.

Registration of Tuberculosis.

Dr. Matthew Woods read a paper on the registration of tuberculosis from the standpoint of private practice. He considers the question of registration a large one, and that probably the majority of the families of this country could point to one relative who had died from the effects of this disease. To register these cases might place a ban upon them. The boy or girl applying for a position might be asked for a health certificate showing that no member of his family had been a sufferer from consumption, and if so might be turned away as being unfit. Italy has tried registration, but the rules were so rigorous that it was abandoned. One of the most beneficent policies in the treatment of these cases is to keep from the patient the knowledge that he has consumption. We may err in the diagnosis of such cases, and he has never seen benefit result from telling the patient that he has tuberculosis. Such knowledge will cause the patient to become more despondent, and too often plunge him into debauchery. He called attention to Goethe and Michael Angelo, both of whom had suffered from pulmonary hemorrhages, the former dying at the age of 88, The death certificate would apprise the health office of a death from tuberculosis and the officials could then disinfect where necessary. Before death the patient should have instructions from the physician in regard to personal hygiene.

Home Treatment of Tuberculosis.

Dr. L. W. Flick read a paper on this subject. By "home treatment" he meant treatment where the disease had been contracted. In his experience it is hardest to keep these patients up to the usual standard of nutrition. The home treatment consists of inclosed and open treatment, the former being that in institutions; the open, where more or less liberty is allowed. Good results have been achieved by the closed treatment, and this may be the method of the future. He considers that one of the greatest drawbacks in any treatment is that the disease is not recognized early enough, and frequently not until an attack of pneumonia or influenza has occurred. Persistent indigestion, with loss of flesh might suggest tuberculosis. When the disease is first recognized, he thinks one of the most important things is to tell the patient that he has consumption, and that no patient ever becomes worse for such knowledge. As to the treatment, he usually limits solid diet to one meal, and gives large quantities of milk, frequently as much as six quarts. Eggs are also valuable, and he allows from six to a dozen a day. Pastries are to be avoided. An abundance of fresh air, both day and night, is imperative. At night the windows should be left open. During the day, the patient may be wrapped up warm and remain in the sunlight, with free ventilation. He may at times be allowed to remain out of doors, or on the roof of his home. Anywhere, so long as he gets plenty of fresh pure air. Of medicines, he relies mostly on the iodin compounds, by inunction. In some cases inhalations may be of service. Arsenic, strychnin, and iron are all good.

Dr. J. C. Wilson also believes that the patient should be told that he has consumption and warned of the danger to others. Hospitals for the treatment of these cases should engage the attention of health authorities.

Dr. R. G. Curtin spoke of certain complications which might be opposed to home treatment. He believes that most patients with tuberculosis do not get enough sunlight. He referred to a case in which pronounced benefit followed an out-door life, in a change of climate, with only a simple diet. As to registration, he spoke of a case occurring at the Philadelphia Hospital, who had suffered for years with an ulcerative process affecting the lung, and had been put in the ward with cases of tuberculosis, yet he lived for years and no bacilli could be found after repeated examinations.

Dr. C. M. Cooper, Edinburgh, being invited to take part in the discussion, stated that in England certain institutions have been established for the treatment of tuberculosis. As a rule these institutions only admit those patients in the early stages of the disease. The results achieved have been good.

Dr. J. M. Anders agreed with the statements of Dr. Flick, and said that over one-half the cases of tuberculosis must be treated at home. Too little detail has been given to home treatment.

Dr. S. Solis-Cohen said that persistent hope on the part of the physician is all-important. His experience is that if the patient is told of his condition it proves beneficial.

Dr. A. V. Meigs believes that registration would not prove beneficial.

Dr. I. J. Mays expressed doubt as to the benefits to be derived from registration.

Dr. Guy Hinsdale said that, regarding the registration of tuberculosis the objections are chiefly imaginary. He does not believe in concealing from the patient the communicable nature of the disease, and thinks that if some treatment—Philadelphia treatment, New York treatment, or Boston treatment—is adopted, it is a makeshift, adopted from necessity. Cases no doubt recover there, lives are also no doubt very much prolonged by treatment, and therefore the principles that have been laid down must be applied daily. He contrasted the conditions found in a well-managed hospital with those in the homes from which the poorer patients come, the change being quite as great as when a patient with means is sent to one of our well-known sanitariums or health resorts. People who leave their homes for hospitals, sanitariums or even open resorts will do a great deal more for themselves under the new circumstances than they would have done at home. They will rise at 6 a. m., to drink mineral waters at a spring a half mile away; they will join an early procession walking barefoot on the damp grass; or they will readily conform to a regime, adapted to the needs of a tuberculous invalid, that they would soon tire of at home. The force of example helps them to keep in line with the rules best adapted for them. But left by themselves, in their homes, the patient who has some prospect of being cured will often neglect himself, and the physician may lose sight of him for long periods when the cough or other symptoms are not urgent, but when medical oversight is needed in just the same degree.

He does not think the prime requisite for treatment can be had in city homes. We do not realize how impure city air is until we go into the forest or to the seashore. It is like trying to cure diphtheria without antitoxin, or malaria without quinin, to treat pulmonary tuberculosis without pure air, and there is no such thing as pure air in our homes, no matter how well constructed, if we make mountain or sea air the standard. There is too much dust, smoke, carbonic acid gas and other products of exhalation, not to speak of pathogenic organisms. Another objection to our city homes is the fact that under ordinary conditions, during the colder season, we are subjected to great transitions of relative humidity of the air. We leave a house heated by a furnace, in the rooms of which the air has a relative humidity of 25, 30 or 35 per cent. We pass out into an atmosphere of 60, 70 or 80 per cent. relative humidity, and so we go in and out and adapt ourselves as best we can to these variations. Under the open air method of treatment, the patient has few if any of these transitions; he takes the humidity as he finds it night and day, for the most part. If he happens to be in Colorado or New Mexico, he has dry air all the time. Here he is inclined to make his "home" out of doors, and when he accomplishes that I will thoroughly indorse the "home" treatment of phthisis.

The place where a person has contracted phthisis is *not* a good place to remain in for treatment. If the patient is too poor or too advanced in his disease to go elsewhere, we have no alternative. But it has been observed that most consumptives live or die according to their strength of character in adjusting their life wisely to their disease, and for this reason many can not to be trusted to live again among the environments in which the disease has been acquired.

JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY.

Meeting held March 4.

Dr. Howard A. Kelly in the chair.

Pernicious Anemia with Symptoms of Spinal Disease.

Dr. Thomas McCrae exhibited two cases, both males. One a laborer, aged 38, dates his sickness from December, 1898. He was able to work until March, 1900. Just before the latter date, he suffered from a carbuncle, and now complains of stiffness and numbness in his arms and legs. Knee-jerk is exaggerated. There is no complaint of the anemia, although hemoglobin is 50 per cent. and red corpuscles 2,500,000.

The second was an elderly man, whose sickness began 1½ years ago, when he fell down stairs and afterwards could not work. He complains of numbness of the limbs and holds himself stiffly, walking with stiffness and difficulty. The knee-jerks were elicited only with difficulty. Hemoglobin was 73 per cent. and red corpuscles 3,500,000.

Both patients are taking arsenic, and the first has very bad teeth, of significance in view of the recent investigations of Hunter, who believes that caries of the teeth bears an etiologic relationship to the disease.

Dr. W. S. Thayer said he had seen similar cases, with marked ataxic symptoms, although none had occurred in the hospital. He regards the outlook in such cases as very bad. He has been astonished to hear the value of arsenic in pernicious anemia and leucocythemia questioned recently by a distinguished Boston clinician. There is positive evidence of its usefulness in these conditions. Sometimes this occurs with great rapidity, although he acknowledges it is but temporary.

Frequency of Gall-Stones in the United States.

Dr. Celia D. Mosher said that the records of 1655 autopsies, 1038 male and 617 female, made at the hospital have been carefully analyzed, and Dr. Welch has assured her that no gall-stones were overlooked in these cases. Of the 1655, 6.4 per cent. were found to have gall-stones. This corresponds to the smallest prevalence reported in Europe. The majority of cases here occur after 30, and the maximum is reached after the age of 40. The condition is less frequent in the colored than in the white race, and males were affected only five-ninths as often as women. Examination of the records at the Almshouse (Bayview Asylum) shows that the paupers there have gall-stones twice as often as the hospital patients. She could offer no explanation of the greater frequency among the paupers and Europeans. As to the greater prevalence in women, she thinks it may be due to tight-lacing and the wearing of belts.

Dr. H. A. Kelly said he had for some time been in the habit of examining for gall-stones, and also into the condition of the appendix, in all cases of laparotomy, and he has found gall-stones present in 8 per cent. of all his patients, and especially with ovarian tumors.

Diabetes Mellitus Associated with Hyaline Degeneration of the Islands of Langerhans in the Pancreas.

Dr. Eugene Opie spoke of his latest researches on these bodies, which resemble the glomeruli of the kidney. They appear to have some relation to the blood. The most common lesion of the pancreas is inflammation. Diabetes does not occur in all cases of pancreatitis, and Dr. Opie has studied cases of the former, to find, if possible, the peculiarity in the pancreatitis with which it is associated. He has been able to distinguish two forms of pancreatitis. In one of these the islands are involved, in the other not, and it is with the former only that diabetes occurs. The condition found is a hyaline degeneration of the islands; the nuclei disappear and they become hemogeneous in appearance, sometimes granular. In obstruction of the pancreatic duct, as from calculus, or pressure, or in ligation of the duct in dogs, the acini are destroyed, but the islands remain intact; hence there is no diabetes in these cases. Dr. Opie, therefore, found in these peculiar lesions one cause of diabetes. Yet not all cases of the latter are associated with lesions of the pancreas, and there are still other facts regarding it which remain to be elucidated.

Dr. T. B. Futcher said that Dr. Opie's discovery was the most important addition made, in recent years, to the pathology of diabetes. From the facts elicited, it would seem probable that the islands of Langerhans elaborate some internal secretion, which is absorbed directly into the blood, and in some way is connected with diabetes.

Carcinoma of the Male Breast.

Mr. Warfield gave the results of his researches on this subject. There have been, altogether, 307 cases of carcinoma of the breast in the hospital, since its opening in 1889. Of these, 3 only have been in males. He has reports of 2 other male cases, which he has seen, outside the hospital, and 32 cases reported in the literature, making 37 in all. Of the 37, 18 occurred in each breast, and in 1 case the side was not given. The largest number in any decade was 13, between 60 and 70 years. In 28 there was no pain. In only 1 case was there a history of carcinoma in the family, the patient's mother having had this affection of the breast. Trauma bore a conspicuous part in the etiology in many cases. The cases that occurred in the hospital were designated in the records as "carcinoma simplex," a name to which Dr. Halsted objected as being indeterminate.

DENVER AND ARAPAHOE MEDICAL SOCIETY.

Meeting held February 26.

Diphtheria, its Treatment in Different Phases.

Dr. W. K. Robinson read a paper on the above subject, and related the histories of six cases recently treated by antitoxin. His conclusions are that the mortality is *nil* in all cases treated the first day with antitoxin, and that very large doses of the antitoxin should be used when the case is seen late in the disease.

Case of Double Bladder, Each with Separate Ureter, with a Study of the Urine of Both Kidneys.

Dr. E. P. Hershey reported the above rare case in a woman 28 years of age, who has been treated all her life for trouble connected with her bladder. When she was very young she had scarlet fever, and soon after that developed bladder symptoms, of which incontinence was the most annoying. Violent exercise would bring on pain. She had severe attacks of pain in the bladder, accompanied with fever and delirium about twice every year. At such times she would pass pus from the bladder. After the pus has been evacuated, which the patient learned to do by either pressing her finger upon the anterior wall of the vagina or by taking large vaginal douches, the symptoms would abate. Dr. Hershey made a careful study of the case and found that she passes two kinds of fluids from the external orifice of the urethra at different times. She passes either urine or pus. The two are never mixed. She passes urine more frequently. The pus passes only after it accumulates for a few days. The patient knows when the pus begins to accumulate. By introducing a catheter about one inch, he can, by directing it upward, obtain normal urine, and by pointing the curve downward obtain pus. Vaginal examination reveals a vesico-vaginal diverticulum. The left kidney is palpable and tender on pressure. He has examined the patient under various conditions (postures) after having washed the two bladders separately, having previously given her various drugs—methylene blue, etc.—and the results were uniform. His diagnosis is: Left surgical kidney, double bladder, each having a separate ureter.

Dr. Leonard Freeman, who examined the case carefully, said that there are not a dozen instances of double bladder mentioned in medical literature. He has seen, however, several of diverticulum of the bladder. He is not sure it is a double bladder; it may be a single one with a transverse partition. He could elicit pain in the kidney by pressing upon the diverticulum in the vagina. He dwelt upon the difficulties with which the surgeon may meet when operating on such cases.

Report of Operations for Radical Cure of Hernia.

Dr. C. A. Powers reported thirty-two cases of radical cure of hernia performed during the last six years, made upon twenty-nine patients, with only one death. The death occurred in a patient 35 years of age, and in the best of health, upon whom he operated for a reducible inguinal hernia. A tumor below Poupart's ligament was found to be a femoral hernia, which was also operated on. Two days after the operation the patient became restless, had a chill, and the wound became puffy. Pus was found at the saphenous opening. Chills continued and the patient died from pyemia and septic pneumonia. Dr. Powers ascribes the fatal issue to the use of kangaroo tendon, which probably was not thoroughly sterile.

Dr. Leonard Freeman has seen suppuration following the radical operation for hernia, and believes it is due to infection carried by the fingers of the operator, impossible of prevention by any other method except wearing rubber gloves. It is important to find out that there are no holes in the gloves, a matter hard to ascertain. He purposely punctured gloves, and filled them with water and there was no leakage. To avoid possible injury to the gloves he used instead of needles, a ligature carrier.

Dr. I. B. Perkins reported a case in which he used two kinds of sutures, and all the kangaroo sutures suppurated.

CHICAGO SOCIETY OF INTERNAL MEDICINE.

Meeting held February 26.

The president, Dr. John A. Robison, in the chair.

Municipal Prevention of Disease.

Dr. Heman Spalding read a paper on this subject. He stated that every municipal health officer should be invested with great discretionary powers, to be used when the more desirable methods of persuasion and education fail to protect the public against disease. He should have the power to enforce the prompt reporting of all infectious and contagious diseases by physicians and citizens; also the power to remove any person, sick with an infectious or contagious disease, to a place where there will be no danger of communicating it to others; and the power to enforce vaccination at all times. He should have at his command a well-equipped isolation hospital for smallpox, one for diphtheria, one for scarlet fever, one for tuberculosis, and another for measles, and it would be well to have one for whooping-cough. The isolation hospital is necessary for those who have no means at home for the proper care and precautionary measures necessary to prevent the spread of contagion.

Living Rooms Back of Stores.—The building ordinance of a large city should prevent the abominable and criminal practice of a family living in the rear of a store or shop of any kind. The partition between a store or shop and the living-rooms should be substantially built and air-tight, and no communication with the store or shop should be allowed through this partition. Scores of times the essayist has found children sick with scarlet fever, diphtheria or smallpox in the living-rooms in the rear of a store or shop, where a flimsy board partition half way up to the ceiling concealed the disease that was carried to the front room and conveyed to the patrons of the store, by the mother or father who acted as nurse to the sick and clerk for the store. It often occurs that the fear of injuring business prevents the shopkeeper from employing a physician, knowing that the doctor will report the case to the health department if he is called. The sale of milk should be prohibited from any store or shop that has any direct communication with living apartments.

Education of People Necessary.—We must have proper and efficient laws as a basis for controlling communicable diseases, but the greatest factor in keeping contagious and infectious diseases out of a city is the education of the people as to the danger of contagion, and how to destroy it and avoid communicating it to others. Every large city needs an intelligent, persistent and authoritative distribution of correct information upon the subject of infectious and contagious diseases. If this information is freely and persistently given out, the sum-total of the knowledge on this subject will be greatly enlarged, even among the most ignorant, and it will be a perpetual aid in saving children from sickness and death. The general practitioner will do good every time he informs a family that scarlatina and scarlet fever are different names for the same disease. Hundreds of people believe scarlatina to be a harmless, non-communicable disease. He will do good every time he teaches a family that varioloid is only another name for smallpox. There are many people who believe varioloid is not contagious, although all have a fairly clear idea that smallpox is contagious. He could give instances where smallpox has been transmitted to others because of ignorance of the true nature of the term varioloid. Life can be saved by correcting the erroneous impression, held by the laity, that measles in a child is comparatively harmless. The death-rate from this disease in children under 2 years of age is not less than 20 per cent. of those attacked. The same is true of whooping-cough. The profession should continue to instruct the people in correct methods of caring for those suffering from infectious disease and continue to preach cleanliness everywhere.

Dr. William A. Evans followed with a paper on "Individual Prophylaxis," which will appear in The Journal.

Immunity as a Factor in the Prevention of Disease.

Dr. Adolph Gehrmann, who read this paper, briefly presented such facts as have value in an experimental or practical way toward proving the efficiency of certain methods in preventive medicine. Outside of the practical application of vaccination against smallpox, the entire development of preventive inoculation began with Pasteur's studies of chicken cholera, anthrax and hydrophobia. The aim of his research was essentially toward artificial immunization, while the German students evolved true curative methods. Although in some cases there may be doubt, still, apparently every infectious disease develops more or less resistance in the infected individual when he recovers. It would, therefore, appear that the strongest development of acquired immunity would be occasioned by an attack of the disease which is just short of killing the individual. Theoretically, preventive inoculations are most scientific, but they can only become practically permissible when the life of the susceptible one is beyond doubt assured. It is unreasonable to consider that acquired immunity has absolutely defined relations toward possible infection. It is always a matter of degree dependent on some recognized factors, as age of the individual, his general vitality and the severity of the immunizing experiment, as well as upon more remote factors, as chemical constitution of his tissues and the rapidity of metabolic changes. It is, therefore, almost impossible to say, in any individual case, what the results of preventive inoculation will be as regards thorough protection and duration of the protective influence. A repetition of the experiment in times of exposure should have less danger attached than in the original inoculation. There is only one way in which to positively test immunity, and that is by an exposure to suitable virus. It can be stated that active immunity is only preventive and should never be attempted for curative purposes; while passive immunity is both preventive and curative, with its greatest value as a curative agent.

After summarizing the results of the workers in the various fields, Dr. Gehrmann stated that how far preventive inoculation can be carried in protecting an individual against a number of diseases must at present remain an open question. It would seem more rational to limit the immunization of patients against bacterial diseases to such times as they are in danger of exposure or have been exposed.

Diet and Exercise as Preventive Measures.

Dr. N. S. Davis, Jr., said that indiscretions in diet, and failure to take exercise, are among the most important causes of ill-health. While the illnesses that result from dietetic indiscretions and from lack of sufficient exercise are, for the most part, of minor importance, in that they do not create much mortality, and therefore do not appear in the death returns, yet they are of the greatest importance. They limit the amount of work individuals can do. The frequency with which maladies occur, due to indiscretions of diet, can not perhaps be more strongly stated than in the words of Sir Henry Thompson, who has said that more than one-half of the diseases which embitter the middle and latter part of life—among, at least, the middle and upper classes of the people—are due to avoidable errors in diet. If this is true, it is perfectly evident that fully one-half of the maladies in middle and later life are affections which can be prevented under careful supervision of physicians, and which should be carefully studied from the standpoint of prevention. It is hardly necessary to more than mention the fact that errors in diet and dietetic management are among the most common causes of ill-health in infancy and in the early years of childhood. Physicians are familiar with the illnesses that arise from indiscretions in diet, and those that lead perhaps to fatal results, and therefore the mortality statistics have been vastly improved by the introduction of measures in large communities for the prevention of many of the illnesses that arise from improper feeding in infancy and childhood.

In order to prevent the dissemination of food which might propagate disease, the universal public inspection of food would help very greatly. Almost all of the parasites that are conveyed by food can be destroyed by heat—by cooking. Therefore, proper cooking is of the utmost importance as a means of preventing the dissemination of illnesses in this way.

Dr. Davis discussed at considerable length the questions of too much exercise and not enough exercise. Finally, he emphasized the importance of food and of exercise as factors in the production of disease, and, when rightly regulated, serving as factors in the promotion of health.

Dr. Daniel R. Brower followed with a paper on "Prevention of Insanity," which will be published in The Journal.

NEW YORK ACADEMY OF MEDICINE.

Meeting of the Section of Medicine, held February 19.

Dr. John H. Huddleston in the chair.

Pleurisy.

Dr. James J. Walsh presented a brief paper, founded on the work of Widal, on "Cyto-diagnosis." This method consists in examining some of the centrifuged pleuritic exudate with the microscope. The earlier the stage at which the examination is made, the more numerous are the polynuclear cells. Mechanical pleurisy, he said, is characterized by the presence of patches of endothelial cells, while pneumococcus pleurisy is characterized by the presence of a few red blood-cells, a few scattered lymphocytes and many mononuclear cells.

Dr. Alexander Lambert discussed "The Bacteriology of Acute and Chronic Pleurisy." He said that 30 to 40 per cent. of all primary pleuritic effusions are known to result from tuberculosis. Syphilis is not a rare cause, and pneumococcus infection is common, the effusion often being purulent.

Dr. C. E. Nammack treated "Early and Late Tapping in Pleurisy." He gave the following rules for guidance: 1, when life is directly threatened by asphyxia from compression or from cardiac weakness; 2, when the fluid has risen to the third interspace anteriorly, as such effusions rarely disappear spontaneously; 3, in all lesser effusions where spontaneous absorption is unduly delayed, resort to tapping. In a general way, the rule may be laid down that when an effusion has remained stationary for more than one week, a portion should be removed by aspiration, as this will often in itself be sufficient to cause the entire removal of the fluid.

Dr. C. H. Lewis read a paper on "The Use of Methylene Blue Injections in Pleurisy with Effusion." He said that he had been led to devise this method of treatment not only because he had learned that spontaneous absorption gave permanent results, but because it had occurred to him that if by the injection of some substance the formation of adhesions could be promoted, subsequent aspiration would effect a prompt cure. Methylene blue accomplishes this, and is an antiseptic, diuretic and anodyne. He withdraws a certain quantity of the serous effusion, mixes it in a graduate with 10 or 15 grains of methylene blue, and returns the mixture to the pleural cavity. In the 23 cases of serofibrinous pleurisy so treated, the average duration of treatment was fourteen days.

Dr. Julius A. Becker described "The Routine Treatment of Pleurisy at the Mount Sinai Hospital." He said that where pleurisy follows an attack of rheumatism, antirheumatic remedies are prescribed. The pain is relieved by the local use of blisters, the Paquelin cautery and strapping, and by the internal administration of morphin, codein or heroin. It is the custom to aspirate a case of serous pleurisy as soon as there is evidently much interference with the action of the lung. The records show that this practice has shortened the duration of the disease, and has reduced to a minimum the thickening of the pleura and the permanent crippling of the lung. The occurrence of pain, or coughing, or the withdrawal of a little blood-stained fluid should be taken as an indication that no more fluid should be aspirated. In no case has there been a severe hemorrhage, or has empyema been traced to infection at aspiration. When there is a large purulent effusion, it is better to remove some of the pus by aspiration before operating, as by this means the danger of shock from the sudden withdrawal of a large quantity of fluid is diminished.

Dr. M. Manges expressed some doubt as to the practical outcome of Widal's labors. The judicious removal of a portion of the effusion holds out the best chance of recovery, though it should be borne in mind that it is quite possible that the presence of a small quantity of fluid in a case of tuberculous pleurisy may be beneficial. He has seen one death result from simple aspiration.

Dr. H. Lilienthal suggested that in performing thoracentesis the danger of skin infection should be avoided by nicking the skin with a knife before introducing the aspirating needle. For cases of empyema he advocates a large opening as preferable to the use of a drainage-tube, and cautions those who prefer to use the tube to be sure that it is no longer than is absolutely necessary. After the operation, it is advisable to make use of Koenig's method of postural drainage.

Dr. S. S. Burt said that while he has been much interested in the methylene blue treatment, he has been backward about giving it a trial because of some experiments published about five years ago, and which seemed to prove that this substance causes acute parenchymatous degeneration of the kidneys and liver and acute catarrh of the bladder.

Dr. Andrew H. Smith also emphasized the importance of using a very short drainage-tube in the chest. He advises his patients, on recovering from pleurisy, to make frequent efforts to aid the expansion of the lung by simply closing the nostril and making a gentle expiratory effort.

Dr. Henry P. Loomis said that he had long ago come to look upon the occurrence of pleurisy with effusion in a case of pulmonary tuberculosis as a conservative effort of Nature, and is accordingly slow to interfere with its under these circumstances. He believes that it acts beneficially by splinting the lung and securing rest for this organ.

Dr. Egbert H. Lefevre said that his own studies in cytodiagnosis, following after Widal, ended in discouragement. Long before there is any outpouring of fluid in serous pleurisy there is a restriction of the movements of the affected side. He has a very high opinion of the value of the salicylate of sodium as a remedy for promoting the absorption of the fluid. In his hands, the best local application has been inunction with blue ointment.

Dr. William H. Thomson called attention to the need for caution in gymnastic exercises, particularly those requiring motion of the arms over the head, after pleurisy. He always instructs his patients on this point, because he has known hemorrhage to occur even several years after an attack of pleurisy, simply as a result of such exercise causing rupture of adhesions. It is well to have the chest strapped for six months after a pleurisy.

Dr. Lewis, replying to Dr. Burt concerning the possible deleterious action of methylene blue, said that in his cases the urine has been carefully examined daily during the treatment, and there has not been the slightest evidence of any harmful effect on the kidneys.

SAN FRANCISCO COUNTY MEDICAL SOCIETY.

Meeting held in San Francisco, February 12.

President Dr. George H. Evans, in the chair.

Bacteriologic Diagnosis of Diphtheria.

Dr. W. H. Kellogg read a paper on this subject. He said that the fact that the Klebs-Loeffler bacillus is the cause of diphtheria, is demonstrated by: 1, its constant presence; 2, its isolation in pure culture: 3, the reproduction of the disease in animals by inoculation with pure culture; and 4, the finding of identical lesions and distribution of organisms in the experimental as in the original disease. The nature of the pseudomembrane was described, and the author gave a thoughtful description of the morphology and cultural characteristics of the bacillus. He detailed the technic of conducting the bacteriologic examination. Several slides should be prepared from each culture-tube, one from each kind of colony that appears; or, if an even layer is present, material should be taken from different parts of the tube. It frequently happens that the bacteriologist fails to find the organism in cases that are true diphtheria, and this may be due to the fact that an antiseptic spray has been used not long before taking the swab, or the swab may have been faultily infected. Another source of error lies in the fact that in cases of mixed infection with staphylococci, the surface of the culture-tube may be thickly studded with colonies of the latter, between which are minute colonies of the diphtheria bacilli, their growth inhibited by the preponderating growth of staphylococci. One negative examination should not, therefore, be taken as conclusive, especially if the clinical aspect of the case does not coincide; but repeated examinations are positive in their results. He referred to the persistence of the bacilli in the throat after the disappearance of the false membrane, and urged the necessity of making later examinations at least once a week in order to determine when to raise the quarantine.

Specific Treatment of Diphtheria.

Dr. George H. Evans read a paper calling attention to the unreliability of statistics when compiled from limited sources of information, but such statistical reports as those furnished to the American Pediatric Society at Montreal in 1896, are to be regarded. Antitoxin was distributed to the physicians of San Francisco by the board of health of that city, for use among the destitute poor, from November, 1897, to April, 1900, and from the clinical reports furnished by the attending physicians of the fatal cases, the author drew some illustration of the value of the serum given early and in large doses. The mortality of the patients thus treated was only 13 per cent., but he believes that this mortality could have been materially reduced had use of the antitoxin been carried out more fearlessly. Thus, of the fatal cases, a very small minority of them received the serum before the fourth day. Such delay is sometimes unavoidable among the poor, where medical aid is not as a rule called early, but large doses should be used, and of these fatal cases, in only six was as large a dose as 4000 units used; 4000 units can be used as the initial dose in a mild case with absolute impunity, and smaller doses than 2000 units should not be used for any purpose other than immunization. In nasal and laryngeal cases, and cases of mixed infection, 3000 or 4000 units should be considered the minimum initial dose. The large doses given by McCollom, of Boston, were referred to, and the reduction in mortality in the apparently moribund cases since its administration in this way was begun. Disagreeable effects following its use were passed over as comparatively unimportant. The increase in the number of cases of paralysis since its introduction was attributed to the fact that more patients survive, and either recover, or live sufficiently long to become paralyzed. That the paralysis is due to the toxins absorbed and not to the antitoxin, has been quite clearly demonstrated, both clinically and experimentally. Ransom's work in Behring's laboratory was particularly referred to. Thirty-four per cent. of the fatal cases in the San Francisco series had paralysis. Almost all of them were treated late in the disease, and small doses were used in every case, 4000 units being the largest. The indications for the use of antitoxin must depend on the clinical diagnosis. To await the bacteriologic confirmation of the diagnosis is a sacrifice of life in many instances, and particularly is this so in some of the laryngeal forms where no membrane is visible, and where repeated efforts fail to produce any growth on culture-media. Antitoxin and an appropriate syringe should be part of every physician's armamentarium, and in the presence of any suspicious exudate, the serum should be used and then a culture made.

Treatment of Diphtheria.

Dr. W. B. Lewitt, in a paper on the "General and Local Treatment of Diphtheria," said that while he is an ardent advocate of the early and vigorous use of antitoxin, he has not yet arrived at that frame of mind that would lead him to depend in all, or even in a majority of cases, on the good effects of that agent alone. In regard to the general treatment of the disease, the object to have in view above all others is to maintain the strength of the patient by rest and the administration of food and stimulants. He urged the necessity of keeping the blood well charged with the products of digestion, as a means of inhibiting to a great extent the formation of toxins; and, therefore, food should be given every two or three hours, and in quantities as great as can be assimilated. He considers milk the best article of diet, and in children under 5 years of age, it should be the only one. In cases where there is a refusal to take food, he urges forced feeding, having no confidence in rectal alimentation, as the enemas in children are seldom retained, and it is a question how much is absorbed. Stimulants are called for in the majority of cases, and should be commenced early. Regarding the internal administration of iron, he only uses it during convalescence. Referring to local treatment, he recalled the days when tincture of iron, carbolic acid, nitrate of silver, and such drugs were used so commonly in the throats of these patients, and drew a vivid picture of the piteous results of such treatment. Where the membrane is confined to the tonsils, local treatment is not necessary. Where the area is greater, all that can be accomplished by any drug used locally can be done by warm sterile water. He advocates using a stream of warm water through the nasal cavities with an ordinary syringe, thereby washing out the nares, nasopharynx, and pharynx. There is generally much less difficulty in doing this than in making the ordinary application to the throat, and it has the very great advantage that the patient does not have to be raised from the recumbent position. In considering laryngeal cases he referred to the good results obtained at the Children's Hospital by the use of creosote in vapor, and the sublimation of calomel. By this method he thinks the necessity of intubation or tracheotomy is frequently done away with, and life prolonged until the good effects of the antitoxin become manifest.

Sequels of Diphtheria.

Dr. Wm. Fitch Cheney read a paper on this subject. He drew a distinction between the diseases occurring coincident with diphtheria, which are more properly called complications, and the true sequels which are the diseases that come after it, as a consequence of it. These are: 1, disease of the blood; 2, disease of the heart; and 3, disease of peripheral nerves. Disease of the blood commonly follows diphtheria in the form of a severe grade of anemia, and calls for the usual remedies employed for secondary anemia. Disease of the heart is either the result of a myocarditis occurring as a complication, or is due to changes in the nerves supplying the heart muscle. The heart muscle almost invariably suffers from parenchymatous or fatty degeneration, to a greater or less extent. and under the influence of the diphtheritic toxins circulating in the blood, and the condition of the pulse should be carefully watched even after convalescence is well established. The treatment of this condition consists first of all in rest. Rest in bed should be insisted on for at least one week, and better for two weeks, after the temperature has become normal and the throat is free from membrane. If the pulse, in spite of this rest, develops any variations from the normal, whisky must be used freely and strychnin given regularly in full doses.

Disease of peripheral nerves is the most common sequel of diphtheria, and is a neuritis. caused by the absorption of toxins manufactured by the bacillus in the throat. Autopsies on human beings and experimental evidence prove this. The paralysis resulting from this neuritis is usually not serious, except where it involves the muscles of respiration, and the heart muscle. It is always difficult to say how much of so-called "heart failure" after diphtheria is due to changes in the myocardium and how much to changes in the nerves supplying the heart muscle. Sudden death may occur from either; the premonitory changes in the pulse are practically the same in each; and fortunately the same treatment that is indicated for one is equally indicated for the other. The author thinks there is no relation between the severity of the diphtheria and the occurrence of the paralysis. He considered the question as to whether treatment of the primary disease with antitoxin has power to prevent the occurrence of paralysis as doubtful, but comparing the report presented to the American Pediatric Association in 1896, with other statistics on the incidence of paralytic sequels, the difference is slightly in favor of the antitoxin treatment.

Referring to the treatment of the paralyses involving the palate, the eyes, and limbs, recovery ultimately takes place regardless of interference, but probably more promptly, by the use of strychnin and iron tonics internally, and the application of electricity externally; however, the most valuable element of all in the treatment is time. On the other hand, the forms involving the action of the heart and lungs too often end fatally in spite of every therapeutic effort. The measures to be employed in the treatment of respiratory paralysis are absolute rest, strychnin hypodermically in full doses, and electricity applied to the respiratory muscles by the Faradic current. For threatened cardiac paralysis the treatment is again complete rest, strychnin hypodermically, and alcoholic stimulants by the mouth or under the skin.

Syphilitic Reinfection Simulated.

Dr. A. B. Grosse reported a case simulating syphilitic reinfection—a banker, aged 37, who eleven years ago had a primary lesion, followed in seven weeks by secondary symptoms. He was subjected to an antisyphilitic treatment for three years, after which he was given permission to marry. He has two children, aged 7 and 2½ years respectively, both of whom were born at term and are healthy at present. His wife is healthy and has had no miscarriages.

After a suspicious coitus on Oct. 30, 1900, he was seen by the doctor on November 24, who found an ulceration to the left of the frenum, which looked like confluent ulcerated herpes. The sore was not indurated. One gland in the left groin was enlarged, and others of the groin were palpable; the epitrochlear and axillary glands were also palpable, and there was enlargement of several cervical glands. On November 28 he was very much improved, and on December 7 was absolutely well, with no sign of a scar. On Jan. 8, 1901, having taken a dose of antipyrin for headache the day before, a roseola of the trunk and limbs appeared—no itching attending it—and an adenopathy as before. On January 11 small papules were found in the center of several of the roseolar spots, which were slightly squamous. On January 16 the rash had entirely faded.

On January 22 a similar rash came on immediately after taking 20 grains of antipyrin, but had entirely disappeared by February 2, and on February 13 he had another outbreak after taking the same drug.

The case showed the necessity of carefully observing a patient before making a diagnosis of reinfection. While the eruption differed from any antipyrin rash he had previously seen described, the doctor thinks we must consider antipyrin as the only etiologic factor, as the rash was produced three successive times after the ingestion of the drug.

PHYSICIANS' CLUB OF CHICAGO.

Meeting held February 25.

Dr. William E. Quine in the chair.

The Ravages of the Venereal Diseases.

Dr. J. Clarence Webster discussed "Their Extent: Can they be lessened?" He stated that their extent and ravages might be considered from many points of view. Unfortunately, a great deal of accurate information regarding any of the venereal diseases is not obtainable as applied to many centuries. Although much is known about syphilis at the present time, there is considerable discussion as to how late it appeared among the Caucasians. There is one school that holds that syphilis was only known in Europe after Columbus discovered America, and it is said that his sailors imported the disease from the West Indies to Europe. Another school believes that syphilis was known in China and Japan many centuries before the discovery of America.

With regard to the gonococcus, the speaker quoted a passage from Leviticus, supposed to have been written by Moses, which is taken generally to refer to gonorrhea. In 1872 Noeggerath published a paper in which he drew attention to gonorrhea and placed it in a new light, and it is owing to Noeggerath's work that the profession holds its present views regarding the importance of this disease in the community. This author stated that of every 1000 men in New York City, 800 have this disease; that of every 100 men who have gonorrhea, 90 per cent. are never cured. He also holds that 3 out of every 5 married women in New York suffer from the effects of this disease. There is no more important factor in producing disease, misery and distress in women than gonorrhea. He is perfectly certain that the rank and file of practitioners look on gonorrhea in women as did our forefathers, and that our present knowledge of the gonococcus and its ravages has not permeated the ranks of the profession. If the rank and file of the profession do not understand these things, it is not to be wondered at that the laity do not. Noeggerath's views are not very well known by the laity. A chronic gonorrhea may be apparently cured, but there may remain a condition which might not be called chronic, but rather latent. Latent gonorrhea in the male is not very well understood. It has been quite clearly shown that in females the gonococcus acts only on the urethral mucosa primarily and on the mucosa in the cervix. It does not attack the vagina nor the vulva, because it can not penetrate the stratified epithelium like the vagina or vulva. However, in certain cases it may do so. In young children a typical gonorrheal vaginitis or vulvitis may be observed. In old women, with thin epithelium, typical vaginitis may be noticed, and particularly in connection with women in labor. In pregnancy and labor a large percentage of women are attacked as a result of the softening, the thinning, the bruising of the tissues, so that the gonococcus plays an important rôle at this time. Latent gonorrhea in the female, as in the male, has a tendency to change into an acute virulent condition at these times. There is no doubt but a man may cohabit with a woman for a long time and never give her any trouble; the gonorrheal virus may never reach the uterus, and the small amount of discharge which comes from the male penis may never affect the urethra or other parts of the woman, but let her become pregnant and the risk is enormously greater. Let her be at the end of pregnancy, and the risk is still greater. If the public were educated to put themselves under the care of the very best physicians and demand the most careful, conscientious and constant treatment for weeks and weeks, the effects of gonorrhea would be enormously reduced, particularly as applied to males. The same thing holds with regard to women. The ordinary routine treatment of women who have gonorrhea by the vaginal douche is of very little avail. The physician should get at the seat of the disease at once, namely, the urethra, the orifices of the ducts of the Bartholinian glands, and the mucosa of the uterus. Not one physician in a hundred treats acute gonorrheal cases in that way. He trusts to luck, and prescribes an ordinary diet and rest. He believes the ordinary treatment of gonorrhea in the female is responsible for the enormous amount of inflammatory mischief which is so commonly found.

Dr. Harold N. Moyer discussed the subject of "Circum-sion in Restricting the Spread of Syphilis." His paper will pear in The Journal.

Dr. Edmund Andrews spoke of the "Diminution of Venereal iseases by Educating the Public." He said that the periodical ess, consisting of the newspapers and the magazines, can, if it ill, do a great educational work. There is, however, an obacle of large dimensions before them. The American people e the most squeamish of all nations as to any public allusion sexual matters. Any warning and information on the subct of venereal diseases would drive away subscribers and reck the finances of any periodical venturing on it, unless the eas were expressed with almost superhuman caution and licacy. Therefore, at present, the profession can not comand efficient help from the press. Yet he thinks the public's ueamishness is slowly abating. If the profession does its ty, the time will come when the periodicals will give some sistance.

Each physician acting in his own individual capacity can do uch to educate the public. There are over one hundred thound medical men in the United States. Each of them on the erage has a patronage of about seven hundred persons, and stands before them as a trained and trusted expert, whose inion in such matters is valued above every other in the mmunity. Physicians are not hampered like the stockholds of periodicals. They have a thousand opportunities to eduate their patrons and others about sexual vices and venereal seases. Already the public owe to their family physicians arly all they know on this subject, and if physicians do their ty they can educate the public still more.

Recently, Dr. Frederic Bierhoff, of the Berlin General Poliinic, made a study of the sources of 381 cases of gonorrhea in ales, with the following result: The persons from whom the isease was contracted were as follows: open prostitutes, 12; andestine prostitutes, 44; kept mistresses and actresses, 138; orking women and servant girls, 167, and married women, 20. he chief of police in Berlin informed the speaker that there re grave reasons why it is impossible to completely enforce e law. He judged that he could only keep about one-fourth the actual prostitutes under his control. He added that r important reasons he could not undertake the regulation kept mistresses, nor of several other classes of loose women; lso, it is to be remembered that a registered woman between xaminations may carry infection from one male patron to nother without having the disease herself.

In educating the public the medical profession can sometimes ork through other professions. For instance, if physicians go t it in the right way they can do a great deal of good through he clergy. The two professions have to some extent weakened heir forces by pulling against each other instead of working eartily together in an alliance to promote morality and good anitation. Both sides have been at fault. The clergy are very highly educated and honestly devoted to the intellectual and moral advancement of the nation. Being almost as numerous as physicians, they have a powerful influence in every community, so that in planning for the sanitary education of the public, it is important to secure their co-operation. Morality and sanitary science are natural allies and ought to march forward hand in hand. Meanwhile, the clergy, like the press, are a little hampered in public expression by the squeamishness of modern society; yet they contrive to preach sermons without offense on the seventh commandment and to denounce both sexual and all other immorality. If they possessed a little more education on venereal diseases, they could with their constant opportunities for confidential advice do much to make their knowledge of disease a powerful weapon against vice, and thus promote both morality and health. A few sanitary lectures added to the curriculum in theological seminaries would furnish every graduate with the necessary facts.

Another power is the great army of teachers. Even outside of the classrooms, they become by their daily contact with others very influential and well-trusted advisers. In the normal schools and other institutions where they prepare for work, they should have a brief course on the prophylaxis of all infectious diseases. In conclusion, Dr. Andrews confessed that a complete education of the adult public is impossible, but he believes that by slow degrees the profession can diffuse light enough into the darkness to be a valuable guide to those who now wander in the mists of ignorance.

Prof. Charles R. Henderson, of the University of Chicago, discussed the moral aspects of the subject. He said that every man is a moral leader, and those who possess special knowledge of the venereal diseases are particularly responsible, in his opinion, for the kind of teaching they give, making allowance for human frailties and weaknesses. One of the curses of the present day is the free distribution of quack literature among young people. The distributors of such literature should be flogged.

Dr. Joseph Zeisler spoke of the establishment of special hospitals for the treatment of venereal diseases, saying it is to be regretted that there is not a hospital in Chicago for taking care of such cases. Chicago is considerably larger than Vienna, yet Vienna has a hospital in which there are 600 beds for the management and treatment of these diseases. In Paris there are hundreds of beds in hospitals, for the same purpose. The principal reason why we have no hospitals in this community for the treatment of venereal diseases is because our public-spirited citizens have not the courage of their convictions. There is not a single intelligent man among the millionaires of Chicago who does not know that there is need for such a hospital. The educational value of such institutions, aside from the treatment and care of such patients, would be immense to physicians. Students would have the advantage of seeing a large amount of material, and of receiving instruction in regard to the venereal diseases by eminent men. Were such hospitals established in this and other cities, it would not be long before an avalanche of scientific knowledge would come forth which would be of incalculable benefit to the medical profession.

Judge Lorin C. Collins spoke of the "Control of the Venereal Diseases by Legislative Enactment." He did not think any large number of the physicians present would agree on what would be proper legislative enactment for the purpose of controlling and diminishing venereal diseases in the community. If physicians should substantially agree among themselves, they would run up against a very powerful body, the public, who probably would not agree with physicians. The same is true of legislators. He was a member of the legislature in 1879, when St. Louis licensed the social evil by an ordinance passed by the city council, and he believes there was passed in the legislature an emergency clause bill prohibiting the licensing of prostitution by any city in Illinois. He thinks that if a hospital were established for the cure of venereal diseases, it would meet with very strong and determined opposition, the opposition contending that in establishing hospitals for the cure of venereal diseases it would be encouraging immorality and vice. This opposition would come from the best classes in the community, from the members of churches. The constitution of this state says that the right of trial by jury, as heretofore enjoyed, shall remain inviolate, and that no man shall be deprived of his life, liberty or property except by due process of law. A case was cited by the speaker. If a man, in the most virulent and dangerous stage of smallpox, should walk down Clark Street, there is no power in Illinois by which that man can be taken and carried forcibly to a place where he can be isolated. No law will authorize this. Many years ago he examined the public health laws of England, and stated that their method of treating venereal diseases is more by persuasion than by force. A person afflicted with a venereal or contagious disease is persuaded to enter a hospital for treatment, and the British law contains no provision whereby a person suffering from smallpox, for instance, can be taken by force to a hospital for treatment. A person may be fined for spreading contagion; he may be imprisoned if the fine is not paid, but he considers this of no value whatever. The person must be taken at the right time by a summary process. He said that we are more particular in this state in all matters affecting the liberty of the citizen than any state in the Union, and this has been the tendency of the Illinois Supreme Court, therefore, anything physicians might do toward securing legislative enactment for the control of venereal diseases would have to be done very carefully and conservatively. Chicago could not pass an ordinance that would be efficacious. Power has not been granted the city as yet by the state, and it would be necessary to have legislation on this subject by the general assembly. He feels that something should be done toward legislative enactment for the control of venereal diseases, and he believes a move on the legislature of the state, with such a body as the medical profession back of it, would be a great educational force which would lead to the dissemination of information on these subjects and would eventually bring about some good. But any measures for the control of the venereal diseases would have to be handled in a conservative manner, and they would have to be very judicious to meet with the approval of the solons at Springfield.

Dr. L. Blake Baldwin said that one public-spirited citizen had already spent more than $3000 toward a hospital for the treatment of venereal diseases, and that this hospital was established last June, since which time the speaker has filled over 1600 prescriptions for gonorrhea and syphilis. He has at present in the institution forty patients suffering from either gonorrhea or syphilis, or both.

Dr. John M. Dodson firmly believes that the time has come when the medical profession should take more active measures to extend the knowledge which it has acquired in recent years in regard to the prevention of diseases, and of public hygiene in a general way. He suggested that the profession, through its organized societies and medical colleges, especially those connected with institutions of general learning, should institute extension courses, so that a series of lectures, carefully prepared and illustrated properly, may be given to the various members of social clubs and other organizations. He believes, through the medium of such organizations and institutions, that lectures on sexual physiology and anatomy, also on the venereal diseases, their dreadful consequences and proper mode of prevention, would do a great deal of good in this city, if wisely conducted.

Dr. Denslow Lewis expressed satisfaction that this symposium had been held. He referred to instances where mawkish sentimentality had prevented a free discussion of these important matters even in professional circles. He condemned illiberal criticism of honest efforts to benefit humanity by calling attention to the truth. He favored a thorough investigation of all matters pertaining to sex relationship and venereal diseases, and a diffusion of knowledge of these subjects. He urged the consistent study of infection as occurs when other infectious diseases are considered. The education of the child in sexual matters is of great importance, and can scarcely begin too early. Young boys should appreciate the dignity of virility. They should understand that when they grow up to be men, under suitable restrictions of civilization, religion and education, they may hope to be privileged to indulge the sexual function as their fathers have done before them for the perpetuation of the species. They should be taught that nothing in their youth should debase them or interfere with the performance of this function at the proper time under suitable conditions. They should be taught also that young women are under their protection; that under proper restrictions these young women will become mothers, and for that reason nothing should be done to them which will debase them or interfere with the proper performance of their functions. They should be taught regarding the venereal diseases in detail; they should know that gonorrhea is not a simple disease, as ordinarily understood, and that syphilis may last for years, affecting the nervous system when all outward manifestations of the disease have disappeared. These matters are of the greatest importance in diminishing the ravages of the venereal diseases. They can only become known by proper instruction by competent medical men. Furthermore, among married people these matters should receive attention. He believes that in many instances venereal diseases are contracted because the sexual relations between husband and wife are unsatisfactory. He thinks it is the duty of physicians to instruct the men and women of their clientele regarding the details of the sexual act. He believes it to be the part of wisdom for physicians to speak out frankly and honestly to patients in that regard, for, oftentimes, even the integrity of the home is threatened when the sexual relations between husband and wife are not mutually agreeable.

The subject was further discussed by Drs. Charles S. Bacon, Hugh T. Patrick and L. Harrison Mettler.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Seasickness.

Memphis, Tenn., Feb. 27, 1901.

To the Editor:—Will you give a short statement of the causes, symptoms and best mode of treatment of seasickness? In causes, I mean the pathology, if any is known. And kindly refer me to some text-book where I can find something about seasickness. Subscriber.

Ans.—The pathology undoubtedly lies in the disturbances of the cerebral circulation, producing anemia of that organ. The symptoms are nausea and vomiting of the severest type, accompanied by great mental depression.

Dr. Daniel R. Brower recommends for such patients the following outline of treatment: Avoid excessive fatigue and mental worry for several days previous to sailing; proper attention must be given the gastro-intestinal tract by taking a light diet and producing free catharsis by means of a full dose of massa hydrargyri, followed at the proper time by a saline purgative. This treatment should be carried out two or three days before going on board ship. As soon as there has been a thorough evacuation one teaspoonful of the following should be taken three times a day until time to go aboard:

℞. Potassii bromidi ....ʒv 20|
Aq. menthæ piperitæ q. s. ad............℥ii 64|

M. Sig.: One teaspoonful in water three times a day.

As soon as the patient arrives on board ship he should take a dose of chloralamid (gr. x-xv, 0.66-1), lie down and remain in a horizontal position until at sea and when the effects of the medicine have worn off, he should move around on deck to ascertain whether he has obtained his "sea legs," to use the nautical expression. If he finds that he is still inclined to be seasick the dose of chloralamid should be repeated, followed by a light diet consisting of easily-digested food, which should be taken at frequent intervals, even though not inclined to eat. He should remain on deck as much as possible.

Dr. H. Rawlins states that seasickness can be relieved by elevating all the limbs. The object in doing this is to augment the blood-pressure, and thus diminish the anemia of the nerve centers due to the enfeeblement of cardiac action when in the nauseated state.

T. Lauder Brunton recommends wearing a tight bandage around the waist extending from the ensiform cartilage to the umbilicus or lower. Rockwell states that large doses of the bromids must be taken, beginning three days before the voyage. As much as thirty grains three times a day may be sufficient, but in some cases still larger doses are necessary. He prefers *the sodium to* the potassium salt. The late Dr. Beard, of New York, has written an interesting article on this subject, which has been published in book form.

Treatment of Smokers' Gingivitis.

R.	Salol	gr. xv	1
	Tinct. catechu	ʒi	4
	Spts. menthæ pip	℥iv	128

M. Sig.: One teaspoonful in half a glass of water as a mouth wash. —*Indian Med. Jour.*

Treatment of Furuncles.

℞.	Ichthyol		
	Etheris sulph.		
	Alcoholis—50 per cent—ãã	ʒiv	16

M. Sig.: Apply locally after shaving the part, and repeat in order to form layers of ichthyol over the part.

Treatment of La Grippe.

Dr. W. H. Thomson, in *Med. News*, states that for the relief of the general aching and pains in the bones aconite is the best drug. This modifies the state of congestion in the capillaries and quiets the heart. Next to aconite Dover's powder gives most relief. He recommends the following combination:

℞.	Ext. aconite—solid	gr. i-vi	06-36
	Pulv. ipecac. et opii	gr. i	06
	Phenacetini	gr. viii	5
	Quininæ sulphatis	gr. vi	36

M. Ft. pilulæ No. ii. Sig.: Take six such pills the first day and each succeeding day until the fever subsides; then three a day until the catarrhal symptoms have disappeared.

We wish to call the practitioner's attention to the very large dose of aconite in the above pill, ranging as it does from grain one-half to three grains in each pill. The usual dose is from gr. ¼ to ½.

Nasal Obstruction in the Newborn.

Chauveau, in *Gaz. Hebd. de Méd. et de Chir.*, states that eczematous impetigo may, by its secretions, occlude the nares of a newborn infant. An acute coryza may be responsible for the obstruction. For the latter condition he advises three or four drops of the following solution to be introduced into the nose three or four times daily:

℞.	Resorcin	gr. xv	1
	Ol. vaselini	℥iss	48

M. Sig.: Introduce three or four drops into the nares three or four times daily; or

℞.	Sodii biboratis	ʒiss	6
	Glycerini	℥i	32

M. Sig.: Drop two or three drops into the nares three times a day.

Vomiting of Pregnancy.

Baer recommends the following combination in vomiting of pregnancy:

℞.	Bismuthi subnitratis	ʒii	8
	Pepsini sacchari	ʒi	4
	Sodii bicarb.	ʒss	2
	Sacch. lactis	ʒi	4

M. ft. chart. No. xii. Sig.: One powder every three hours.

In addition he advises the following:

℞.	Acidi nitro-hydrochlor dil.	ʒiss	6
	Spts. limonis	ʒi	4
	Syr. simplicis	℥ii	64

M. Sig.: One teaspoonful in a wine glass of ice water three times a day.

Removal of Cerumen from the Ear.

Dr. Godart, as published in the *Phil. Med. Jour.*, recommends the following to remove wax from the ear:

℞.	Sodii carb.—pure	gr. xv	1
	Glycerini		
	Aq. destil. ãã	ʒv	20

M. Insert a few drops into the ear several times a day, followed by irrigation with water at proper temperature,

Infection of the Breast During Lactation.

C. S. Bacon, in *N. Y. Med. Jour.*, states that when the nipple wounds become infected, but before there are any symptoms of general infection or involvement of the deeper breast, the local wounds may be treated by the application of cotton saturated with alcohol. Nursing through a shield may be allowed.

When the symptoms of deeper infection appear, nursing from the affected breast should not be allowed and the breast should be supported and put at rest by a bandage. By following this plan of treatment 80 to 90 per cent. of all breast infections will terminate without abscess. If in spite of this treatment some temperature continues or reappears, the presence of pus must be expected and the breast opened.

To Relieve the Itching of Urticaria.

℞.	Alcoholis		
	Spts. etheris		
	Spts chloroformi, ãã	ʒviiss	30
	Menthol	gr. ii	12

M. Sig.: Use as a local application.

Iodin in Liver Spots.

Dr. M. Porasz, as noted in *Merck's Archives*, states that the best means of removing pityriasis versicolor, or liver spots, is tinctura iodi. In from three to four days after painting the spots with this preparation the skin begins to desquamate, which process is completed in four or five days. The separated epidermis takes along with it the spores and mycelia of the parasitic fungus.

Treatment of Seborrhea with Benzene.

Leftwich, in *Brit. Med. Journal*, states that the treatment of seborrhea sicca with alkalies or with bland oils for the removal of the crusts has not been satisfactory. As the crusts are made up chiefly of fat, he states that benzene makes a good solvent by *applying* it with a shaving brush over the affected area; the *thick crusts soon disappear.* The benzene leaves the scalp very dry, and he advises the cleansing to be followed by an inunction. For this he prescribes:

℞.	*Ol. ricini*		
	Spts. myrciæ, ãã	℥iss	48
	Tinct. cantharidis	ʒii	8
	Eau de Cologne	ʒiv	16

M. Sig.: Apply to the part every morning and repeat the benzene treatment once in five days.

The effect of the benzene on the baldness is also very satisfactory. To conceal the odor the author advises the addition of ten drops of oil of *geranium* to each ounce of benzene. In mild cases of seborrhea the benzene is mixed with equal parts of alcohol.

Treatment of Tonsillitis.

Dr. Cheveller, in *Klin. Ther. Woch.*, states that he treats all kinds of tonsillitis with the following gargle:

℞.	Sodii salicylatis	ʒii	8
	Aq. menth. pip. q. s. ad	℥vi	192

M. Sig.: Use as a gargle several times a day.

Treatment of Acne of the Face.

In mild cases of acne, Dr. A. Phillopson recommends the following:

℞.	Acidi acetici		
	Tinct. benzoin		
	Spts. camphoræ, ãã	m. xlv	3
	Alcoholis, q. s. ad	℥iiiss	112

M. Sig.: Put on some cotton and rub the face night and morning.

morality and vice. This opposition would come from the best classes in the community, from the members of churches. The constitution of this state says that the right of trial by jury, as heretofore enjoyed, shall remain inviolate, and that no man shall be deprived of his life, liberty or property except by due process of law. A case was cited by the speaker. If a man, in the most virulent and dangerous stage of smallpox, should walk down Clark Street, there is no power in Illinois by which that man can be taken and carried forcibly to a place where he can be isolated. No law will authorize this. Many years ago he examined the public health laws of England, and stated that their method of treating venereal diseases is more by persuasion than by force. A person afflicted with a venereal or contagious disease is persuaded to enter a hospital for treatment, and the British law contains no provision whereby a person suffering from smallpox, for instance, can be taken by force to a hospital for treatment. A person may be fined for spreading contagion; he may be imprisoned if the fine is not paid, but he considers this of no value whatever. The person must be taken at the right time by a summary process. He said that we are more particular in this state in all matters affecting the liberty of the citizen than any state in the Union, and this has been the tendency of the Illinois Supreme Court, therefore, anything physicians might do toward securing legislative enactment for the control of venereal diseases would have to be done very carefully and conservatively. Chicago could not pass an ordinance that would be efficacious. Power has not been granted the city as yet by the state, and it would be necessary to have legislation on this subject by the general assembly. He feels that something should be done toward legislative enactment for the control of venereal diseases, and he believes a move on the legislature of the state, with such a body as the medical profession back of it, would be a great educational force which would lead to the dissemination of information on these subjects and would eventually bring about some good. But any measures for the control of the venereal diseases would have to be handled in a conservative manner, and they would have to be very judicious to meet with the approval of the solons at Springfield.

Dr. L. Blake Baldwin said that one public-spirited citizen had already spent more than $3000 toward a hospital for the treatment of venereal diseases, and that this hospital was established last June, since which time the speaker has filled over 1600 prescriptions for gonorrhea and syphilis. ℞.	Resorcin	gr. xv	1
	Ol. vaselini	℥iss	48

M. Sig.: Introduce three or four drops into the nares three or four times daily; or

℞.	Sodii biboratis	ʒiss	6
	Glycerini	℥i	32

M. Sig.: Drop two or three drops into the nares *three times* a day.

Vomiting of Pregnancy.

Baer recommends the following combination in vomiting of pregnancy:

℞.	Bismuthi subnitratis	ʒii	8
	Pepsini sacchari	ʒi	4
	Sodii bicarb.	ʒss	2
	Sacch. lactis	ʒi	4

M. ft. chart. No. xii. Sig.: One powder every three hours.

In addition he advises the following:

℞.	Acidi nitro-hydrochlor dil.	ʒiss	6
	Spts. limonis	ʒi	4
	Syr. simplicis	℥ii	64

M. Sig.: One teaspoonful in a wine glass of ice water three times a day.

Removal of Cerumen from the Ear.

Dr. Godart, as published in the *Phil. Med. Jour.*, recommends the following to remove wax from the ear:

R.	Sodii carb.—pure	gr. xv	1
	Glycerini		
	Aq. destil. āā	ʒv	20

M. Insert a few drops into the ear several times a day, followed by irrigation with water at proper temperature,

Infection of the Breast During Lactation.

C. S. Bacon, in *N. Y. Med. Jour.*, states that when the nipple wounds become infected, but before there are any symptoms of general infection or involvement of the deeper breast, the local wounds may be treated by the application of cotton saturated with alcohol. Nursing through a shield may be allowed.

When the symptoms of deeper infection appear, nursing from the affected breast should not be allowed and the breast should be supported and put at rest by a bandage. By following this plan of treatment 80 to 90 per cent. of all breast infections will terminate without abscess. If in spite of this treatment some temperature continues or reappears, the presence of pus must be expected and the breast opened.

To Relieve the Itching of Urticaria.

R.	Alcoholis		
	Spts. etheris		
	Spts chloroformi, āā	ʒviiss	30
	Menthol	gr. ii	12

M. Sig.: Use as a local application.

Iodin in Liver Spots.

Dr. M. Porasz, as noted in *Merck's Archives*, states that the best means of removing pityriasis versicolor, or liver spots, is tinctura iodi. In from three to four days after painting the spots with this preparation the skin begins to desquamate, which process is completed in four or five days. The separated epidermis takes along with it the spores and mycelia of the parasitic fungus.

Treatment of Seborrhea with Benzene.

Leftwich, in *Brit. Med. Journal*, states that the treatment of seborrhea sicca with *alkalies or* with bland oils for the removal of the crusts has *not been satisfactory*. As the crusts are made up *chiefly of fat*, he states that benzene makes a good solvent by applying it with a shaving brush over the affected area; the thick crusts soon disappear. The benzene leaves the scalp very dry, and he advises the cleansing to be followed by an inunction. For this he prescribes:

℞.	Ol. ricini		
	Spts. myrciæ, āā	℥iss	48
	Tinct. cantharidis	ʒii	8
	Eau de Cologne	ʒiv	16

M. Sig.: Apply to the part every morning and repeat the benzene treatment once in five days.

The effect of the benzene on the baldness is also very satisfactory. To conceal the odor the author advises the addition of ten drops of oil of geranium to each ounce of benzene. In mild cases of seborrhea the benzene is mixed with equal parts of alcohol.

Treatment of Tonsillitis.

Dr. Cheveller, in *Klin. Ther. Woch.*, states that he treats all kinds of tonsillitis with the following gargle:

℞.	Sodii salicylatis	ʒii	8
	Aq. menth. pip. q. s. ad	℥vi	192

M. Sig.: Use as a gargle several times a day.

Treatment of Acne of the Face.

In mild cases of acne, Dr. A. Phillopson recommends the following:

℞.	Acidi acetici		
	Tinct. benzoin		
	Spts. camphoræ, āā	m. xlv	3
	Alcoholis, q. s. ad	℥iiiss	112

M. Sig.: Put on some *cotton* and rub the face night and morning.

Pertussis.

Dr. Roth has treated a great number of cases of whooping cough, with the following combination containing iodin and carbolic acid, with splendid results:

℞.	Acidi carbol.	gr. xv	1	
	Spts. vini gallici	ʒss	2	
	Tinct. iodi	m. x		66
	Tinct. belladonnæ	ʒss	2	
	Aq. menth. pip	℥iii	96	
	Syrupi opii	ʒiiss	10	

M. Sig.: A teaspoonful every two hours to a child over two years of age. —*Med. Summary.*

It will be seen, if Dr. Roth is quoted correctly, that the child would be taking one-half grain of carbolic acid every two hours, or twelve grains in twenty-four hours, which is a poisonous dose.

Treatment of Sore Nipples.

℞.	Balsami peruviani		
	Tinct. arnicæ, ãã	ʒss	2
	Ol. amygdal. dulcis		
	Aq. calcis ãã	℥ss	16

M. Sig.: Shake well and apply to the nipple with a camel's hair brush. —*Med. Summary.*

Medicolegal.

Sufficiency of Basis for Non-expert Opinion of Sanity.—The Supreme Court of Iowa states, in the will case of Betts vs. Betts, that there is some authority for saying that it is not within the province of the court to pass upon the sufficiency of the information upon which a non-expert witness rests his opinion of a person's mental condition; that this is a matter for the jury. But, without indorsing this doctrine, it states that it has to say that no general rule can be laid down as to what opportunity for observation will be sufficient. Courts, it adds, should be slow to make any hard and fast rule, for all the facts out of which the opinion grows are given the jury.

Presumption of Accidental Death.—In the absence of evidence to that effect, the Supreme Court of California holds, in the case of Jenkin vs. the Pacific Mutual Life Insurance Company, that it will not be presumed that an insured person, who died from a gunshot wound, purposely took his own life, nor that he was murdered, but that his death must be attributed to accidental causes. That the courts will presume that the death was the result of an accident, when nothing more is shown than that it was brought about by a violent injury, and the character of such injury is consistent with the theory of accident, it declares, seems to be a rule upheld by the great weight of authority.

"Self-Destruction" Under Life Insurance Policy.—The United States Circuit Court of Appeals, Fifth Circuit, holds, in Union Mutual Life Insurance Company vs. Payne, that "self-destruction," as used in a contract of insurance stating that it, sane or insane, is a risk not assumed by the company, means suicide, and does not include accidental self-killing. In other words, accidental or unintentional self-killing does not forfeit a policy for suicide. Moreover, the court holds that a statement in the proof of death that the insured committed suicide is not conclusive of that fact against the person making it, and does not relieve of the burden of proof the company setting up suicide as a defense, although it is admissible as evidence of suicide, and, in the absence of explanation or contradiction, might be quite sufficient evidence thereof.

Presumption of Miscarriage from Accident.—The Appellate Court of Illinois, first district, holds, in Strehmann vs. the City of Chicago, that the fact of a miscarriage in two months after an accident, coupled with the evidence of the woman's physician that the accident, as described by her, might have caused the miscarriage, and no other cause having been proved, it would be a reasonable inference that the accident caused the miscarriage. Certainly, it says, it would be a question for the jury, on all the evidence, whether the accident was the efficient cause of the miscarriage. And it holds that it was calculated to mislead the jury for the trial court by an instruction to single out one fact in evidence, namely, the birth of the still-born child, not stating other facts in evidence, and inform the jury that such fact considered alone did not tend to prove that the accident was the proximate cause of it.

Can Not Dispose of Dead Body by Will.—The Supreme Court of California says, in the case of Enos vs. Snyder, that the general English and American authorities are not very satisfactory bearing on the contest where next of kin, on the one hand, and claimants under a will, on the other hand, demand possession of a body for the purpose of burying it. However, it considers it quite well established by those authorities that, in the absence of statutory provisions, there is no property in a dead body; that it is not part of the estate of the deceased person; and that a man can not by will dispose of that which after his death will be his corpse. Between next of kin and an executor or administrator as such, it holds that the custody of the corpse and the right of burial belong to the former, and says that it has been generally declared in the American cases, that the right of burial of a deceased wife or husband belongs to the surviving spouse, and in other cases to the next of kin, being present and having the ability to perform the service.

City Not Liable for Damages in Enforcing Quarantine.—The Supreme Court of Texas concurs, in what is now entitled the case of White vs. the City of San Antonio, with the Court of Civil Appeals of Texas, in holding that an action did not lie against the city for the wrongs complained of, as stated on page 1175 of The Journal of Nov. 3, 1900. This was an action brought to recover of the city for the acts of its mayor and health officer in taking possession of the plaintiff's hotel and placing and detaining therein certain persons suspected of having been exposed to the infection of yellow fever. The supreme court says that the enforcement of quarantine regulations and the establishment and maintenance of pest houses are matters of vital interest to the public in general, and are peculiarly a public function, and therefore, when devolved upon a city, are most generally held to belong to that class of duties for which a city is not answerable, when, through the negligence or misconduct of its officers in their performance, damages are inflicted. The rule, it adds, is recognized by the leading text writers, and is maintained by courts of the highest authority. Moreover, it considers that the provisions of the Texas statutes which make the health officers of a city officers of the state, show that their functions are governmental, and are conferred in the interest of the public at large, so that this rule clearly applies to their acts.

Injuries in Consequence of Effect of Intoxicants.—The Court of Appeals of Kentucky states one of the exceptions from the insurance contracted for in the case of Campbell vs. the Fidelity and Casualty Company of New York to have been of injuries, fatal or otherwise, received in consequence of having been under the influence of or affected by intoxicants. And it says that there seems to be a dearth of direct authority upon the question of what injuries may properly be said to have been received in consequence of having been under the influence of or affected by intoxicants. This clearly, it holds, does not include injuries such as disease resulting from the direct or indirect effect upon the system of the intoxicants. But it thinks that this language applies to injuries received in consequence of the effect of intoxicants upon the nerves, the mind, or the disposition of the insured. For example, it applies where a man's nerves are so unsteady from the use of intoxicants that he loses his balance upon the edge of a precipice, and falls; where his mind is so affected by their use that he does not see a present danger, but deliberately walks into it; or where his passions are so excited, and his temper so warped, that he recklessly does acts in themselves dangerous, or which naturally tend to produce dangerous results from others. Under this view, it follows that it is not necessary, in order to come within this exception of the policy, that the insured should be so far under the influence of intoxicants as to be in what is ordinarily termed a state of intoxication or drunkenness, but only so far under the influence of or affected by them that incapacity, nervous or mental, or the excitement of passion, should be such that injury results in consequence of it.

Damages for Miscarriage from Assault.—The Supreme Court of Minnesota holds, in the case of Plonty vs. Murphy, that, on the trial of a civil action for the recovery of damages for an alleged assault on a woman pregnant with child, an alleged result being a miscarriage, it is not necessary, in order for the plaintiff to recover substantial damages for this particular injury, that she show by testimony that she suffered more pain, or increased illness, or greater impairment of health, than she would if the delivery of the child had been at the proper time and in the natural way. Here the defendant unjustifiably intruded himself upon the plaintiff by entering the kitchen in which she was at work, remained about ten minutes, talking in an excited and angry manner, shook his first at her when within striking distance, and raised his hand as if he would strike her. This conduct excited her fear, she did not sleep that night, had bearing-down pains next morning, commenced to flow within three days, and eight days afterward was delivered of a six-months' child, which, if living at the time of delivery, expired immediately afterward. The medical testimony adduced at the trial was to the effect that the affair, as related by the plaintiff, could not possibly cause a shock sufficient to produce a miscarriage. But the supreme court says that the jurors were not bound to accept this medical testimony as conclusive, it being wholly based on hypothetical questions, and open to the criticism which can properly be made as to all testimony of this nature. And it holds that not only was the evidence in the case sufficient to support a finding of the jury, in effect, that the defendant committed an assault on the plaintiff, but that, notwithstanding the expert testimony referred to, there was evidence from which the jury could find that the assault was the approximate cause of the miscarriage. It also holds that, in view of this fact, a verdict for $300 was not excessive.

What May Amount to Administering a Drug.—A section of the Indiana statutes provides that, whoever prescribes or administers to any pregnant woman, or to any woman he supposes to be pregnant, any drug, medicine, or substance whatever, with intent thereby to procure the miscarriage of such woman, shall, if the woman miscarries and dies in consequence thereof, be fined, etc. The word "administer" in said section, the Supreme Court of Indiana holds, in McCaughey vs. State, does not signify merely the manual administering of the drug, medicine, or substance, but it has a much wider meaning. Among the definitions of the word are the following: "To furnish; to give; to administer medicine; to direct or cause it to be taken." Webst. Dict. "To supply, furnish, or provide with." Stand. Dict. As used in said section, the word "administer," the court holds, was clearly intended to cover the whole ground named, making it an offense to give, furnish, supply, provide with, or cause to be given, furnished, supplied or provided with, or taken, any such drug, medicine, or substance, with the intent and either result named in said section. And the word, the court holds, embraces, and was intended to embrace, every mode of giving, furnishing, supplying, providing with, or causing to be taken any such drug, medicine, or substance. This it pronounces both the letter and spirit of the section. Moreover, as the section makes it a crime to either prescribe or administer such drug, medicine, or substance with the intent and result named therein, the court holds it immaterial in this case whether the woman knew of the properties of the drug and the purposes for which it was used, or whether she requested the accused to procure the drug for her, or he furnished it to her without such request, or whether she decided to take it before he procured and gave it to her. If he knew or supposed she was pregnant, and knew the purpose for which she desired the drug, and furnished it to her, and she afterwards, when he was not present, took the same, he administered the drug to her, the court holds, in the meaning of the section.

AMERICAN.

1. **Dangerous Operations.**—Deaver's paper is a protest against the indiscriminate use and abuse of three operations, excellent procedures in themselves if properly and justly employed. These are repair of the cervix, curettement, and rapid dilatation of the cervix. What he insists upon particularly is antiseptic preparation of the field of operation, including shaving, use of soap and water, permanganate of potash, oxalic acid, bichlorid of mercury and carbolic acid solutions, with iodoform gauze. These rules of antiseptic detail must be followed. He is a firm believer in rubber gloves, which not only protect the patient, but also the surgeon. We can not boil the hands, but we can boil the gloves, and it is easy to change them in changing operations and thus insure asepticity. He also warns against operations on the cervix or its canal in the presence of a latent or active inflammation, or adhesions binding down the uterus.

3. **Urinary Hyperacidity.**—The fact that certain symptoms of bladder irritation are some times observed without any vesical infection, is noticed by Brown, who finds the cause for some of these rather mysterious cases in an extreme hyperacidity of the urine, which is often itself increased by the increased irritability of the bladder; this hyperacidity being itself attributable to general neurotic, neurasthenic and hysterical conditions or, in other words, it is a vesical neurosis. Nine cases are reported of this condition, relieved by treatment.

4. **Multiple Brain Abscesses.**—Claytor reports a case of multiple brain abscess following empyema, and gives, from the literature, a list of fifty-eight cases of brain abscesses resulting from primary lung disease.

5. **The Suprarenal in Epistaxis.**—Cases of long-continued nasal bleeding obstinate to treatment sometimes occur, and such conditions are the subject of Somers' article. He reports two cases—one of which might be considered extreme in its duration and obstinacy—which were treated by the use of suprarenal extract with great success. The results obtained, he thinks, indicate that it has a further action than that of vascular constriction. It seems to tone up the parts and assist the healing processes like no other remedy. He, therefore, concludes that in addition to its vasomotor effects the drug is of great value for its local nutritive effect and as a pure muscle tonic.

6. **Biochemical Basis of Pathology.**—Bunker's article goes into details of organic chemistry. He comes to the conclusion of Pasteur, that there is some asymmetric force or forces acting in all tissues endowed with life, which is a profound modifier of chemical affinity as manifested in laboratory reactions.

8. **A New Blood-Stain.**—After noticing the stains which have been in favor, such as those of Jenner, Ehrlich, Plehn and Prince, Rosenberger gives the results of his endeavors to find a more durable blood-stain in combination with basic dye. Phloxin showed the granules of the leukocytes beautifully, and methylene blue being one of the best and most uniform stains, he tried these in combination. The formula which worked the best is as follows:

℞.	Saturated aqueous solution of methylene-blue	50
	Saturated aqueous solution of phloxin	20
	Alcohol—95 per cent	30
	Water—distilled	60

He remarks that a precipitate generally forms and the stain needs "shaking before using." The blood-films need to be fixed by heat—115 to 120 C. for 20 minutes—or in equal parts of alcohol and ether, or absolute alcohol. The stain works well in either case. If the preparation is dried from alcohol and ether, the stain is applied and allowed to remain from one to three or four minutes, washed freely in water, dried and mounted in balsam. This is also a fairly good stain for malarial parasites of any variety. It has the advantage of greater durability over those previously employed.

9. **The Use and Abuse of Spectacles.**—The great increase in the use of spectacles is first noticed by Derby, who suggests that ophthalmic physicians as well as opticians may make mistakes. He thinks that probably glasses are worn too much in cases of hypermetropia and too little in myopia. A slight degree of astigmatism, he thinks, can be let alone and, as regards the use of prismatic glasses, it is more and more frequently thought to be the fact that apparent muscular anomalies vary directly with conditions of general health. He, therefore, holds that these may be over-used.

12. **Veratrum Viride.**—This drug, according to Isham, has largely gone out of use among city practitioners, though it still holds its own in the country. He believes there are many cases where its value is not appreciated, and reports six, all of peritonitis, having its origin in appendicitis, in which it was employed with advantage. Its first effects are referable to the glandular system, exciting the sudoriferous glands, the salivary and the liver. These have a therapeutic significance not to be lightly passed over. Especially the action of the sweat glands and of the liver is of importance in aiding the system to overcome toxic states. Its action on the heart also is possibly beneficial. It lowers the temperature through its action on the sweat glands, and he suggests that its direct action on the

neuron may better explain its behavior than the simple statement that it is a depressant of the spinal cord. Its action on the heart muscle itself or its ganglia is suggested, by Isham, to be beneficial in squeezing out waste products and bringing the organ down from an overdistended mechanical organ to one working in perfect order. He believes it may also be a most excellent remedy in acute alcoholism, and the possibility of death produced by it is not considered a serious one.

13. **Delirium Tremens.**—Warbasse reports a case in the practice of Dr. Pilcher, in Brooklyn, where the injection of 40 ounces of saline solution at a temperature of 116 F., into the median cephalic vein in a severe case of delirium tremens, was followed by rapid improvement and recovery. He thinks this method may aid by increasing the amount of circulating medium, diluting the toxins, stimulating excretion, and improving the action of the heart.

14. **Yohimbin.**—This drug, which has been studied in Germany by Loewy, Mendel and others, appears to be a powerful aphrodisiac. From animal experiments it appears to be a central paralyzer of motility, but not of sensibility. This is not a poisoning of the muscles themselves. Mendel has found the drug useful in sexual neurasthenia, but Bartholow hopes we will find it useful in albuminuria, exerting an action of substitution in diseases of the renal and genito-urinary system. More extended clinical experience, however, is required.

15. **Thymotal.**—This name is given to a carbonate of thymol prepared by Pool, which he claims has special advantages in ankylostomiasis. It is a neutral substance with a fusing-point of 99 C., a boiling point of more than 400 C. It gives no other reaction, save that it is divided into thymol and carbolic acid by alcoholic solution of potassium. A boiling aqueous solution of potash does not break it up, and neither acids nor the human stomach have any effect on it. It is odorless, is not vomited, does not cause dizziness, and is broken up in the body by the bile and mucus. Ankylostomiasis, for which it was devised, seems more rapidly affected by it than by thymol itself. For adults, the dose is 30 gr.; for children, 15 gr., and for babies, 7½ gr., three or four times daily. The treatment must be continued for four days, and a purgative be taken on the fifth, after which the whole treatment must be repeated until no more ankylostomata are found in the stools.

21. **The Axis-Traction Forceps.**—Marx reports his experience with the Tarnier axis-forceps and shows their advantages. He also describes a special method which he calls rotary axis-traction, that he has employed and by which rotation can be brought about without the lesions to the soft parts resulting from the use of ordinary forceps in these maneuvers.

22. **Metrorrhagia.**—The etiology of metrorrhagia due to inflammatory processes in the pelvis is discussed by Cragin, who thinks the usual order of source and sequelæ as regards the endometrium is: 1. Chronic congestion; 2, chronic inflammation; 3, menorrhagia and metrorrhagia. The muscle wall of the uterus itself may take part in the production of the symptom through tumors and chronic interstitial inflammation with atrophy of the muscle tissue and increase in new connective tissue. In some cases, however, the condition seems to be caused by lack of sufficient elasticity in the uterine muscle, interfering with normal muscle contraction. The blood vessels of the uterus, if sclerosed, so as to destroy their elasticity, may naturally produce the morbid conditions. Occasional cases are met with where the endometritis is slight and the hemorrhage seems to be due to lack of contractile power in the arterial wall. The treatment of metrorrhagia depends largely on its etiology; with chronic endometritis, curettage and relief of congestion is best; if acute endometritis exists, cleanliness, drainage and rest. If the symptom is due to interference with the muscular contraction of the walls of the vessels, the treatment depends on the presence or absence of hypertrophied endometrium. The presence of the latter indicates curettage, possibly repeated several times. In the absence of hypertrophied endometrium, or if persistent after repeated curettage, metrorrhagia may justify hysterectomy.

24. **X-Rays in Tuberculosis.**—Rudis-Jicinsky reports experiments made by putting sputum in cultures of bouillon in boxes and treating them with the *x*-ray. He found that certain *x*-rays are similar in their actinic properties to the violet rays of the spectrum, and that various bacteria react differently under such radiation, according to the quality of the plasma and the degree of liquid they contained. Mildly alkaline cultures seem to favor the growth of tubercle bacilli, while in acid media they are rendered inert. Rabbits were inoculated from the cultures mentioned, and their secretions rendered acid or alkaline. In these, where the alkaline treatment was given, fatal tuberculosis ensued. In the other case the animals seemed to do well and lived for two years after exposure to the *x*-ray, and examinations showed healed tuberculous lesions. From the results of these experiments he was led to try, the last two years, the *x*-ray in early cases of tuberculosis that came to him for treatment, with the results that from 20 selected cases, in one year there were 2 deaths, 1 of suicide, 4 failures, and the rest are now doing comparatively well. The time of exposure varied from ten to fifteen minutes in each case, the rays exposed at a distance of filteen to eighteen inches from the body and the fluoroscope applied to the opposite side. He will not say that his cases were cured by the *x*-ray exposure only, for there may have been a spontaneous cure, but they certainly got well. As regards the danger of dermatitis, etc., he can prove that there is absolutely none if the exposures are not unnecessarily prolonged and certain precautions are observed. Treatment must be stopped at once, on the first trace of any burning, itching or discoloration of the skin. He believes that this method has a future and is worthy of extended trial.

25. **Gastric Carcinoma.**—After reporting four cases of carcinoma of the posterior wall of the stomach, treated by palliative anastomosis with gastro-enterostomy and the Murphy button, Vanderveer offers the following as practical deductions: 1. In all cases of continued gastric disturbance that do not yield to medical treatment, careful examination and experiments should be made as to the possibility of malignancy being present. 2. Whether positive diagnosis of malignancy is made or not, the patient continuing to emaciate and suffer, exploration should be done and, if there is any malignant growth, gastro-intestinal anastomosis should be made along the lines suggested by Dr. Weir. 3. The malignant growths in the posterior wall of the stomach are certainly more difficult of diagnosis and sometimes escape the notice of the most careful diagnostician. 4. When an exploratory incision shows that malignant growth in the posterior wall is not possible of removal by resection or otherwise, we should not refuse our patient the benefit of gastro-intestinal anastomosis. 5. In all cases the blood should be carefully examined as a part of the history of the patient, in order to learn of the conditions that may have a bearing on the diagnosis.

28. **Rheumatic Deformities.**—Gibney reports twenty cases of post-rheumatic and arthritic joint deformities, with the results of treatment by various methods. It is difficult to fix upon any one form of treatment, but he can not refrain from commending the forcible breaking of adhesions when inflammatory conditions have subsided or frequent recurrence to these operations and the judicious use of plaster-of-Paris. His faith in absolute immobilization as a promoter of absorption of chronic inflammatory products increases year by year. The protection of joints with limited range of motion by apparatus within the bounds of this motion is also to be commended. There is hardly a joint in the body but will tolerate considerable force at certain times. The treatment which has been most efficient he sums up as a judicious management of the case throughout, correction of deformity, partial restoration of function which renders the patient helpful, and improvement is sure to follow.

29. **Inspection of the Female Bladder.**—Pryor describes a cystoscope devised by himself, consisting of a main tube for inspection alongside of which is attached a smaller tube for carrying the lamp and a stem which holds it. The tube for

illumination extends beyond the tube for inspection, and consequently the rays of light project beyond and outside the latter, no rays entering it. The lamp, lampholder and wires are completely insulated. The advantages of this cystoscope are that the tube for inspection is free from obstruction and free from lamp rays, either direct or indirect, the absence of the necessity of focussing rays of light, the passage of rays of light directly to the part to be inspected, absence of disadvantages inherent in the use of Nitze's cystoscope, the perfect ease with which demonstration can be made, and lastly the absence of heat, and of urine about the trigone and the non-necessity of pumping it out. He lays special stress on the posture which seems, from the illustration, to be a sort of combined Trendelenburg and lithotomy position. He points out its advantages over the knee-chest posture.

30. **Ureine.**—Chace and Gies criticise Moor's recent paper on this subject, maintaining that his chemical methods are faulty, that his ureine is not a chemical species, but is a mixture containing several of the organic substances and a considerable portion of inorganic salts originally found in the normal urine, and its toxicity can be referred to some of these. Consequently it adds nothing to our knowledge of the cause of uremia, nor can his deductions regarding the biologic significance of this urinary complex be accepted.

31. **Dislocation of the Thumb.**—After first noticing the different methods devised for reducing thumb dislocation, Erdmann describes his own. In the case of dorsal dislocation, the operator places his thumbs on the base of the proximal phalanx and the cushion of his index fingers on the dorsal extremity of the metacarpal bone. The forces are then applied in the opposite direction; the index finger pulls the metacarpal bone in a condition of extension or abduction while the thumb raises and pushes the phalanx in a position of flexion. Should the rare condition of volar dislocation exist, the procedure in reference to the operator's thumb and index finger is reversed, the thumb lifting and extending the distal phalanges and adduction or flexion of the metacarpal bone made by the index finger. This method has been used by the author since 1887, without any failures.

32. **Tuberculosis in Prisons.**—Knopf remarks on the prevalence of tuberculous disease and describes the precautions that should be taken; the isolation of tuberculous patients from their fellows, etc., the use of masks to catch the germs when coughing, and the various methods to counteract the prison depression. Aside from any sentimentalism, he thinks we should specially endeavor to combat tuberculosis in this class because they are liable to spread the disease on their discharge.

39.—See abstract in The Journal, xxxv, p. 52.

41. **Xeroderma Pigmentosum.**—Wolff reports several cases of this condition occurring in one family in South Carolina. There was no heredity to account for the disorder, so far as known. Of the six children, two boys and a girl were infected. The disease appeared in each instance in the first summer of life after exposure to the sun, as sunburn. The sunburn did not go away until freckles appeared, which spread and deepened; the skin thinned and shrunk in places; then followed ulcerations, outgrowths and ophthalmic complications. The general health, excepting in one patient, remained unaffected.

50.—**Spinal Cocainization.**—Stone reports his experience with spinal cocainization in obstetric cases, and states that the sudden unpleasant symptom of headache can generally be controlled by glonoin in 1/50 gr. doses, or by hyoscin hydrobromate, 1/150 to 1/200 gr. doses, especially if given just before the injection of cocain. It also reduces the frequency of nausea and vomiting. The high temperature which follows he attributes to tampering with the pressure of the cerebrospinal fluid within the canal, as the same symptoms follow the injection of normal saline solution and other internal injections. In one case, where 1/12 of morphin sulphate was added to the cocain injection alarming symptoms of morphin poisoning ensued. He therefore thinks it is unsafe to use it. As regards the dangers, he thinks the only cases of death from lumbar puncture were from those of cerebral neoplasms and hydrocephalus, where the too sudden withdrawal of the cerebrospinal fluid has caused death. The advantages of the method are that the patient is absolutely relieved from pain for hours, the accoucheur is relieved from anxiety after a favorable injection, and the presence of the anesthetist and his expense can be dispensed with. Too much stress can not be laid on the importance of absolute asepsis during the injection.

54. **New Formation of Urethra.**—Noble reports a case in which, after two unsuccessful operations, he performed a third in which he sutured the mucous membrane over the small sigmoid self-retaining catheter, using what was left of the anterior wall of the original urethra and, between the external orifice of the urethra and the clitoris, the mucous membrane of the vestibule was utilized. The left labium minus was selected also as a tissue from which to form a flap. It is easily drawn over the raw surface and well back into the vagina, and attached by interrupted catgut suture to the raw surfaces which had been prepared and sutured with silkworm gut sutures to the right border of the raw surfaces along the urethra and within the vagina. At the anterior end of the new urethra, near the clitoris, the lateral surfaces of the labium majus were sutured together. In this way not only the floor of the urethra was made of the left labium minus, but a flap of considerable thickness was secured over the region of the neck of the bladder. The result was perfect, and he recommends to others who operate in similar conditions, to use the labium minus in this way. So far as he knows, its utilization thus is original with him.

66. **Optic-Nerve Fibers.**—Seggel reports a case, observed by him, in which there was pronounced hemianopsia, which he accounts for by the aid of accessory symptoms, paralysis of the oculomotor nerve, non-impairment of the sense of smell, as due to infection of the posterior portion of the chiasm. He also quotes another case which had already been reported by Seydel, in which there was a fibroma of the dura mater, clinically located, that had been producing pressure on the left papillomacular bundle, and removed, relieving the condition. These two cases, he thinks, serve to prove that the papillo macular bundles lie in the dorso-medial location.

73. **Tension in Atrophic Eyes.**—Ischreyt takes up the question of ocular tension, illustrating his views by cases. Since the intraocular tension depends on the influx and outflow of liquids, its disturbance can only arise through disorders in this relation. The condition of increased tension has been shown possible by the interference with the outflow uncomplicated by diminished influx. If the disturbance has once taken place there is added an increased secretion brought about by this cause. Both factors unite in bringing about the condition known as absolute glaucoma. While in many conditions of hypertony the disturbed relation between influx and outflow depends primarily on the interruption of the outflow and rarely upon the primary hypersecretion, it is natural to assume that hypotony is primarily brought about by diminished influx, and an investigation on atrophic eyes reveals, indeed, marked injury of the secreting portion of the eye—the ciliary processes. As long as diminution in secretion is slight it may be compensated by increased activity of other portions of the secretory area, and also the lack of aqueous humor may be compensated for by contraction of the elastic capsule of the eye, but with any considerable diminution of secretion considerable hypotony occurs. A slight cause may be sufficient to destroy the balance. While the normal channel of exit, the plexus venosus ciliaris, is free, and the hypotony at the most has caused only a slowing of filtration, the destruction of the ciliary processes and the iris forces the blood of the anterior and posterior ciliary arteries into new channels and thus gives rise to an increased anterior venous outflow; the diminution in tension and the increasing of the collapse of the ocular capsule, remove pressure from the vessels entering the venæ vorticosæ and allow them to dilate; the more the pressure sinks the easier is the venous outflow. Thus a vicious circle develops, and results in a condition known as atrophy of the ball. The rapid outflow of venous blood prevents any general diminution in the arterial current, and thus

neuron may better explain its behavior than the simple statement that it is a depressant of the spinal cord. Its action on the heart muscle itself or its ganglia is suggested, by Isham, to be beneficial in squeezing out waste products and bringing the organ down from an overdistended mechanical organ to one working in perfect order. He believes it may also be a most excellent remedy in acute alcoholism, and the possibility of death produced by it is not considered a serious one.

13. **Delirium Tremens.**—Warbasse reports a case in the practice of Dr. Pilcher, in Brooklyn, where the injection of 40 ounces of saline solution at a temperature of 116 F., into the median cephalic vein in a severe case of delirium tremens, was followed by rapid improvement and recovery. He thinks this method may aid by increasing the amount of circulating medium, diluting the toxins, stimulating excretion, and improving the action of the heart.

14. **Yohimbin.**—This drug, which has been studied in Germany by Loewy, Mendel and others, appears to be a powerful aphrodisiac. From animal experiments it appears to be a central paralyzer of motility, but not of sensibility. This is not a poisoning of the muscles themselves. Mendel has found the drug useful in sexual neurasthenia, but Bartholow hopes we will find it useful in albuminuria, exerting an action of substitution in diseases of the renal and genito-urinary system. More extended clinical experience, however, is required.

15. **Thymotal.**—This name is given to a carbonate of thymol prepared by Pool, which he claims has special advantages in ankylostomiasis. It is a neutral substance with a fusing-point of 99 C., a boiling point of more than 400 C. It gives no other reaction, save that it is divided into thymol and carbolic acid by alcoholic solution of potassium. A boiling aqueous solution of potash does not break it up, and neither acids nor the human stomach have any effect on it. It is odorless, is not vomited, does not cause dizziness, and is broken up in the body by the bile and mucus. Ankylostomiasis, for which it was devised, seems more rapidly affected by it than by thymol itself. For adults, the dose is 30 gr.; for children, 15 gr., and for babies, 7½ gr., three or four times daily. The treatment must be continued for four days, and a purgative be taken on the fifth, after which the whole treatment must be repeated until no more ankylostomata are found in the stools.

21. **The Axis-Traction Forceps.**—Marx reports his experience with the Tarnier axis-forceps and shows their advantages. He also describes a special method which he calls rotary axis-traction, that he has employed and by which rotation can be brought about without the lesions to the soft parts resulting from the use of ordinary forceps in these maneuvers.

22. **Metrorrhagia.**—The etiology of metrorrhagia due to inflammatory processes in the pelvis is discussed by Cragin, who thinks the usual order of source and sequelæ as regards the endometrium is: 1. Chronic congestion; 2, chronic inflammation; 3, menorrhagia and metrorrhagia. The muscle wall of the uterus itself may take part in the production of the symptom through tumors and chronic interstitial inflammation with atrophy of the muscle tissue and increase in new connective tissue. In some cases, however, the condition seems to be caused by lack of sufficient elasticity in the uterine muscle, interfering with normal muscle contraction. The blood vessels of the uterus, if sclerosed, so as to destroy their elasticity, may naturally produce the morbid conditions. Occasional cases are met with where the endometritis is slight and the hemorrhage seems to be due to lack of contractile power in the arterial wall. The treatment of metrorrhagia depends largely on its etiology; with chronic endometritis, curettage and relief of congestion is best; if acute endometritis exists, cleanliness, drainage and rest. If the symptom is due to interference with the muscular contraction of the walls of the vessels, the treatment depends on the presence or absence of hypertrophied endometrium. The presence of the latter indicates curettage, possibly repeated several times. In the absence of hypertrophied endometrium, or if persistent after repeated curettage, metrorrhagia may justify hysterectomy.

24. **X-Rays in Tuberculosis.**—Rudis-Jicinsky reports experiments made by putting sputum in cultures of bouillon in boxes and treating them with the *x*-ray. He found that certain *x*-rays are similar in their actinic properties to the violet rays of the spectrum, and that various bacteria react differently under such radiation, according to the quality of the plasma and the degree of liquid they contained. Mildly alkaline cultures seem to favor the growth of tubercle bacilli, while in acid media they are rendered inert. Too much stress can not be laid on the importance of absolute asepsis during the injection.

54. **New Formation of Urethra.**—Noble reports a case in which, after two unsuccessful operations, he performed a third in which he sutured the mucous membrane over the small sigmoid self-retaining catheter, using what was left of the anterior wall of the original urethra and, between the external orifice of the urethra and the clitoris, the mucous membrane of the vestibule was utilized. The left labium minus was selected also as a tissue from which to form a flap. It is easily drawn over the raw surface and well back into the vagina, and attached by interrupted catgut suture to the raw surfaces which had been prepared and sutured with silkworm gut sutures to the right border of the raw surfaces along the urethra and within the vagina. At the anterior end of the new urethra, near the clitoris, the lateral surfaces of the labium majus were sutured together. In this way not only the floor of the urethra was made of the left labium minus, but a flap of considerable thickness was secured over the region of the neck of the bladder. The result was perfect, and he recommends to others who operate in similar conditions, to use the labium minus in this way. So far as he knows, its utilization thus is original with him.

66. **Optic-Nerve Fibers.**—Seggel reports a case, observed by him, in which there was pronounced hemianopsia, which he accounts for by the aid of accessory symptoms, paralysis of the oculomotor nerve, non-impairment of the sense of smell, as due to infection of the posterior portion of the chiasm. He also quotes another case which had already been reported by Seydel, in which there was a fibroma of the dura mater, clinically located, that had been producing pressure on the left papillo-macular bundle, and removed, relieving the condition. These two cases, he thinks, serve to prove that the papillo-macular bundles lie in the dorso-medial location.

73. **Tension in Atrophic Eyes.**—Ischreyt takes up the question of ocular tension, illustrating his views by cases. Since the intraocular tension depends on the influx and outflow of liquids, its disturbance can only arise through disorders in this relation. The condition of increased tension has been shown possible by the interference with the outflow uncomplicated by diminished influx. If the disturbance has once taken place there is added an increased secretion brought about by this cause. Both factors unite in bringing about the condition known as absolute glaucoma. While in many conditions of hypertony the disturbed relation between influx and outflow depends primarily on the interruption of the outflow and rarely upon the primary hypersecretion, it is natural to assume that hypotony is primarily brought about by diminished influx, and an investigation on atrophic eyes reveals, indeed, marked injury of the secreting portion of the eye—the ciliary processes. As long as diminution in secretion is slight it may be compensated by increased activity of other portions of the secretory area, and also the lack of aqueous humor may be compensated for by contraction of the elastic capsule of the eye, but with any considerable diminution of secretion considerable hypotony occurs. A slight cause may be sufficient to destroy the balance. While the normal channel of exit, the plexus venosus ciliaris, is free, and the hypotony at the most has caused only a slowing of filtration, the destruction of the ciliary processes and the iris forces the blood of the anterior and posterior ciliary arteries into new channels and thus gives rise to an increased anterior venous outflow; the diminution in tension and the increasing of the collapse of the ocular capsule, remove pressure from the vessels entering the venæ vorticosæ and allow them to dilate; the more the pressure sinks the easier is the venous outflow. Thus a vicious circle develops, and results in a condition known as atrophy of the ball. The rapid outflow of venous blood prevents any general diminution in the arterial current, and thus

no secondary, compensatory endarteritis develops. As regards the compensatory arrangement of the eye it seems probable that the anterior venous channel of outlet acts as a regulator of circulation in the anterior segment of the ball: in case of interference either in the venous or arterial area the excess blood is easily carried off through these channels.

74.—See abstract in The Journal of January 12, p. 127.

75.—Ibid., p. 125.

83. **Myocarditis.**—The pathology of myocarditis is noticed by Edwards, who remarks that we can not clinically distinguish with absolute certainty the difference between acute and chronic degenerations and inflammations. Much of our present confusion is based upon the fact that the microscope can not gauge the degree of cardiac inco-ordination and often fails to indicate its cause. Chronic myocarditis must be studied in the light of more acute changes in which successive pathologic alterations are most easily observed. It is probably not a disease of itself, but a sequel of previous retrogression. It is a secondary process, it plays no active rôle, but compensates for the destruction of the heart tissue while it is itself a measure of that loss. While valvular disease is not necessarily affiliated with myocarditis, it is indirectly associated with it. The condition may be complicated by partial heart aneurysms and heart ruptures.

84. **Chronic Myocarditis.**—According to Quine, myocardiac diseases are more frequent and important than generally supposed. The false diagnosis of the condition is rarer than the failure to recognize it. Among the earliest symptoms is dyspnea: Cheyne-Stokes respiration commonly occurs during sleep. The patient may not be able to lie down on account of the gravity of the dyspnea. The pulse is ordinarily slow, fever intermittent and irregular. Intermittency is a more common feature than ordinary irregularity. There is often actual pain in the region of the heart, and the irregularity may be felt by the patient himself. The area of cardiac dulness is usually increased, the apex-beat displaced downward. The aortic second sound is accentuated, indicating arteriosclerosis. Increase in the volume of the heart, diminution in the pulse, signs of weakness of the muscles indicate failure. Local and physical debility are common in advanced stages. The pseudo-apoplectic attacks, and occasionally real apoplexy, may be the terminal complications. When the heart muscles begin to yield, dilatation takes place, symptoms of venous congestion appear in all parts of the body—bronchial catarrh, lung edema, liver enlargement, gastro-intestinal catarrh; renal insufficiency is an early and almost constant symptom. Notwithstanding the tendency to somnolency sleep is *unrefreshing and disturbed*. In the advanced stages the cardiac impulse is feeble, the heart signs weak, tremor cordis, vertigo and other symptoms appear.

88. **Prognosis of Chronic Myocarditis.**—The following is the summary of Preble's paper: 1. Chronic myocarditis is an incurable, progressive disease, which does not show itself clinically until considerably advanced. 2. While the prognosis is determined by the site and extent of the process, there is no constant relation between the intensity and duration of the clinical manifestations and the pathologic changes. 3. Because of these facts, the process must inevitably cause death, but it is impossible to foretell whether in a short time or after the lapse of years, and whether it will occur suddenly or after a prolonged period of cardiac insufficiency. 4. The more prominently marked the paroxysmal manifestations, the angina, pulmonary edema, and asthma are, the more probable is sudden death. 5. The more marked any renal, pulmonary or arterial changes are, the more unfavorable the prognosis. 6. The better the habits, financial condition and intelligence of the patient, the better the prognosis, other things being equal.

92. **Angina Pectoris.**—According to Eckley, angina pectoris is a neuralgia of the cardiac plexus from which pain is reflected to all parts of the body. The anatomical order of nerve involvement, both primary and reflex, seems to him as follows: 1. Cardiac plexus. 2. The brachial plexus. 3. The intercostals. 4. The phrenic. 5. The trigeminus.

93. **Enterostomy in Obstruction.**—Senn reports two cases, and in conclusion emphasizes the following points: 1. The value of temporary enterostomy in acute intestinal obstruction in selected cases, especially where facilities are not favorable for a laparotomy, and where the patient's condition does not warrant such an operation. 2. Enterostomy is a simple operation, requiring ordinary skill, while laparotomy with radical treatment of the obstruction is very critical. 3. The opening in the intestine should not exceed one-half inch in length, parallel with the axis of the bowel, thereby readily closing after its purpose has been fulfilled. 4. If the obstruction persists after enterostomy, a radical operation can be performed at a later date, when the acute symptoms have passed away.

101. **Influence of Alcohol on Muscle Work.**—The conclusions of Destree's paper are that alcohol has an apparent favorable effect on the work product, whether the muscle is weary or not, which appears almost immediately, but is very transitory; directly afterward it has a very decided paralyzing effect. About one-half hour after taking alcohol the muscle power reaches the maximum; subsequent doses increase with difficulty. The subsequent paralyzing effect of alcohol outweighs the momentary stimulation. The total work product is less than is produced without it. Similar paralyzing effects are not observed to follow the use of tea, coffee, etc.

102. **The Action of Alcohol.**—The action of alcohol in altering the functions of cells subjected to pathogenic organisms is the subject of Woodhead's article. He calls attention to the experiments and observations of various authorities, especially those of Abbott and Delcarde. These show that attenuated disease-producing organisms, which under ordinary circumstances do not kill, bring about such a result when the animal has been previously treated with alcohol, for example in rabies, tetanus and anthrax, and Delcarde draws the conclusion that patients who have been bitten by a mad dog should abstain from the use of alcohol, not only during the process of treatment, but for a long period afterward, while immunity is being gained. There is no doubt that in addition to its specific action alcohol has a general mal-nutritious effect, in its action on the mucous membranes of the stomach, etc. The susceptibility induced by alcohol to excess is somewhat similar to that induced by starvation, in which we see the resistance of animals to particular forms of infection very markedly diminished.

105. See abstract in The Journal, xxxv, p. 1501.

109. **Degeneration of Spinal Cord.**—The general conclusions derived by Putnam and Taylor are: 1. That a well-defined lesion of the nervous system particularly localized in the cord exists, which may for the present be termed simply "diffuse degeneration." 2. That no fundamental characteristics of the lesion have been found depending on different causes. 3. That anemic states have been shown at times to be a concomitant condition, but not necessarily a cause. 4. That the actual causes are still wholly obscure.

125. **Hematemesis.**—The surgical treatment of gastric hemorrhage is noticed by Armstrong, who reports five cases in which he has himself operated. He offers the following suggestions, putting aside the cases of sudden death: 1. If a patient vomits twenty ounces of pure blood and another twenty ounces in four to six hours, operation should be performed if the surroundings are favorable and the condition of the patient is such as to give reasonable hopes. 2. If a smaller hemorrhage of from four to ten ounces continues to occur at intervals, and medicinal and dietetic treatment or rest fails to arrest in thirty-six to forty-eight hours, surgery is applicable. 3. In so-called chronic cases which are not relieved by three months of medical treatment. 4. In any case and at any time, when, in spite of medical treatment, the patient is evidently passing into a condition of anemia where operative measures can not be undertaken with any degree of safety. As regards the operation, he says it is well to examine for external evidence of internal lesion but, failing to find this, it is well to open the anterior wall sufficiently to enable the thorough inspection of the whole of the mucosa. If the bleeding point can not be found, then pyloroplasty or gastro-enterostomy should be performed with a

view to secure such a degree of rest in the stomach walls as will favor clot and subsequent healing. If the bleeding point is found, treatment will depend on its locality and nature, extirpation of ulcer, ligation, thermocauterizing to stop oozing, etc. After operation, rectal feeding and salines are indicated.

128.—See abstract in THE JOURNAL, xxxv, p. 1500.

129.—Ibid.

133. **Smallpox.**—Bryan suggests the following in the treatment of smallpox: Scrub the skin with strong alkaline soap and water in order to remove the oil naturally existing, and then wash with alcohol and then again with 1 to 500 solution of bichlorid of mercury, following with a solution of peroxid of hydrogen, each of these washings being ten to fifteen minutes in duration. Finally, the parts are well wrapped in an envelope of borated cotton. In the case thus experimented on, this treatment was applied to the forearms and hands, where there was a distinct papillomatous eruption, with the result that the papules in this region failed to become purulent, while in other parts of the body they followed their regular course, with the usual results. He suggests this local method of treatment and alludes to Osborne's treatment as reported in THE JOURNAL for April 28, 1900, as supporting his general views.

138. **X-Rays.**—In his discussion of the *x*-rays and their use in surgery Rhamy says that when the subject and apparatus are so placed that the electric current is felt he fears an *x*-ray burn. The only one he ever had was produced under these circumstances, on himself, and he can produce a burn at will by simply adjusting the apparatus so that he can feel the current, then exposing long enough.

140. **Influenza in Infants.**—The almost invariable influenzal infection of infants during an epidemic is noticed by Zahorsky, who calls attention to the characteristic symptoms: The contagion, typical fever curve, typical appearance of fauces. catarrhal symptoms of upper air-passages, presence of bacilli. The common colds, he thinks, are not due to drafts, etc., but are often the effect of an influenza epidemic. In infants the afebrile form is exceptional. The characteristic fever curve is almost diagnostic. There are certain other signs, however, such as high fever in the morning, great irregularity and frequent relapses. The grippal infection in infants has the following characteristics: The anterior pillars of the fauces and the posterior edge of the soft palate are marked by a congestion, the inflamed margin of the velum palati being sharply defined and usually about one-fourth of an inch wide. The catarrhal symptoms are not so universal, but they are characteristic: The grippal infection of the small bronchial tubes in feeble infants is a very serious matter. The principal symptoms are cyanosis and great dyspnea; the respiratory murmur is feeble; infection of the lungs is not common. The clinical forms of influenza are enumerated as follows: 1. Acute fever with angina. 2. Acute coryza with or without fever. 3. Acute laryngitis with or without spasmodic croup. 4. Acute bronchitis. 5. Acute bronchiolitis. 6. Bronchopneumonia. 7. Lobar pneumonia. 8. Acute gastritis, and gastric duodenitis. 9. Acute myocarditis. Among the rarer lesions he mentions acute leptomeningitis, endocarditis, a peculiar pertussal cough, jaundice, hemorrhagic nephritis, otitis, nervous sequelæ, etc. The treatment is summed up in: 1. Rest and fresh air. 2. Careful attention to the diet. 3. Prevention of secondary infection. 4. Supervision and control of bodily functions.

British Medical Journal, February 23.

Remarks on the Conclusions of the Report of the Anesthetics Committee of the British Medical Association. GEORGE EASTES.—This article gives the conclusions of the report of the Committee on Anesthetics for the British Medical Association, with comments theron. The former can be given only in a somewhat abridged form. The conclusions are deduced from over 13,000 cases of chloroform anesthesia, 4595 of ether, 2071 of gas and ether, 2911 of nitrous oxid, and varying numbers from 155 to over 700 cases of anesthesia from various mixtures—A. C. E. mixture, chloroform and ether, etc. The cases of danger, including deaths, considered to be due entirely to anesthesia, occurred in a percentage of 0.582 per cent. of chloroform anesthesia, and in ether only 0.065. The highest percentage was under the chloroform group, which includes A. C. E. mixture and chloroform, A. C. E. followed by ether, etc., and the average danger rate was 0.584. Under the ether group, including only ether, gas and ether, ether with other compounds, etc., it was 0.085. Although, excluding nitrous oxid, ether was accepted as the safest routine agent, certain circumstances, the state of the patient, nature of the operation, etc., may make some other anesthetic or combination safer and easier. No method of administration of chloroform is safe from danger, but the danger largely depends on the anesthetist. There is no possible conclusion from the evidence as to the best method of administration of ether or gas and ether. The data warrant the conclusion that A. C. E. mixture should not be given in a closed inhaler, and this applies to all mixtures containing chloroform. The committee was not able to give any conclusions as to the best methods of restoration, but finds that anesthesia is more commonly associated with complications and dangers in males than in females, and that, not including infancy and taking anesthetics collectively, the complications and dangers increase with advancing age and the anesthetics are proportionately more dangerous as the gravity of the patient's state increases. Danger to life is specially likely to be incurred in the earlier stages, while the tendency to less grave complications increases with the duration of the anesthetic, and all complications increase with the gravity of operations. As regards chloroform, the Commission finds that chloroform is about twice as dangerous in males as in females. It is most dangerous during early infancy and after 30 years of age, and is more dangerous than any other anesthetic in cases of good health. In grave conditions it is still less safe, but the disparity between it and others is less marked. In a large proportion of cases the symptoms that are observed are those of primary circulatory failure. Imperfect anesthesia is the cause of a large number of cases of danger from chloroform, and vomiting, which may lead to trouble, seems to be more frequent under this drug than under others. Struggling is much more frequent under chloroform; it must also be regarded as a source of danger, and the tendency to circulatory complications increases directly with the relative amount of chloroform in the anesthetic employed. While vomiting is more common after ether, severe and prolonged vomiting is more frequent when chloroform has been used. Circulatory depression following anesthesia is more common after chloroform than after ether, and while the respiratory complications as a whole are equally frequent under ether and chloroform, those that occur under ether are of a trifling and transitory nature, and those under chloroform more grave and persistent. As regards ether, the complications of anesthesia are more frequent in males than in females, but more dangerous to the latter. Ether, when employed throughout or preceded by nitrous oxid or A. C. E. mixture, is singularly free from danger in healthy persons. The minor troubles due to laryngeal irritation and increased secretion are more common than under chloroform and its mixtures. Struggling occurs more frequently when given alone, but rarely leads to danger. The after-vomiting is more common with ether, but is usually transient, and bronchitis is much more frequent as an after-effect. With gas and ether the dangers are more common in females, but the complications are more frequent in males. Of other mixtures, A. C. E. holds an intermediate position between chloroform and ether, being more dangerous in males than females, but in a less marked degree than chloroform. The administration of ether antecedent to chloroform does not abolish the tendency to chloroform dangers. The other various mixtures and successions of anesthetics were recorded too infrequently to justify definite conclusions. As a general conclusion, the committee is convinced that by far the most important factor in the safe administration of anesthetics is the experience which has been acquired by the anesthetizer. In many cases the anesthetization completely transcends in gravity and importance the operation itself. To insure success it is absolutely essential that an anesthetist of large experience should conduct the administration.

The Lancet, February 23.

Passive Effusion into the Knee-Joints, Occurring in Women and Young Girls. William H. Bennett.—Attention is called by Bennett to a painless and unnoticed effusion into the knee-joint of girls of 12 or 13 years of age, and in young women; a number of cases are reported. The alleged cause is often injury, but the condition seems to be somewhat dependent on the catamenial periods and uterine functions. It is well to always inquire into these painless swelling of the knee-joint in girls, say from 13 to 14 years, or women at the climacteric. If these functional irregularities exist there will generally be fluid in both knees, probably more on the right side. Though the patient may be convinced that it is due to some recent injury, the other factor is probably primarily responsible. In the treatment, correct interpretation of these cases is of vital importance. If attention be too much concentrated on the knee alone, the management may be misled. Primary treatment should be directed to correction of the faulty functions, while moderate exercise, massage of the knee and outdoor life are collateral indications. In any case splints and confinement should be avoided. The prognosis is always good provided the primary cause of the effusion can be cured.

The Diagnosis and Treatment of Abscess in Connection with the Vermiform Appendix. Rutherford Morison.—The following are the conclusions of Morison's article: "The early diagnosis of abscess in connection with the vermiform appendix is of great importance. A dangerous abscess may be present without any of the ordinary symptoms or signs of pus formation. The diagnosis is based upon the history of an acute attack of appendicitis and the presence of a definite tender lump. The position of the appendix and the relations of the abscess may be foretold by a careful study of the tumor. The diagnosis of pelvic cases in women is attended by special difficulties. In men and women bimanual examination may clear up an otherwise doubtful case. Spontaneous relief and possible cure may follow the discharge of pus into adjacent bowel. An abscess, though of appendicular origin, may be remote from the appendix and may be residual. Many of such pus collections are due to the localization of a general peritoneal infection which has been recovered from. Early operation is the proper treatment and with few exceptions the vermiform appendix should be removed at the same time as the abscess is drained (pelvic cases form the chief exception to this rule). The abdominal opening should be large enough to permit of perfect inspection of all manipulation and the abscess should be drained from behind."

Annales de la Soc. Med. de Liege, December.

Treatment of Goiter with Large Doses of Iodin. L. Beco.—In the writer's experience in Belgium, persons with goiter are usually anemic. He therefore administers potassium iodid, combined with ferrous iodid. If this treatment prove ineffectual, he orders tincture of iodin internally, which is suspended at the first symptom of gastric intolerance. One patient, with a goiter rebellious to all other measures, was completely cured in a few weeks with tincture of iodin, of which he took from 40 to 120 drops a day without inconvenience. Beco no longer gives it timidly, but increases from 15 to 30 or 40 drops during the first fortnight, and has had only one case resist this treatment. He generally prescribes 25 gm. of fresh tincture of iodin to 5 gm. of potassium iodid: 5 to 40 drops in a glass of water or beer three times a day.

Bull. de l'Acad. de Med. (Paris), February 12.

Appendicitic Black Vomit. Dieulafoy.—Under the influence of the toxic infection of appendicitis, acute hemorrhagic ulcerations may be produced in the stomach, similar to the gastric hemorrhagic ulcerations of pneumococcus toxi-infection, of strangulated hernia, or simple ulceration. The ulcerative process is alike in each; there is an acute hemorrhagic necrosis of some small territory of the mucous lining of the stomach. When an arteriole becomes involved, hemorrhage occurs, which is more or less copious, repeated or fulminating. The alterations in the liver—icterus and urobilinuria—are due to the toxins generated in the appendix, as are also the alterations in the kidneys—albuminuria, oliguria, anuria and symptoms of uremia. The stomach lesions and hematemesis also form part of the appendicitic toxic syndrome, isolated or associated with other manifestations. Dieulafoy has observed six cases of this complication during the last nine months, all but two rapidly fatal, the patients being from 10 to 68 years of age. The operation was performed on the third or fourth day after the commencement of the appendicitis in each case, too late to prevent the progress of the toxic processes. The hematemesis appeared soon after, and was fatal at its second recurrence. Lucas-Championnière reports a somewhat similar case cured by alkaline lavage of the stomach.

Gazette Med. Belge (Liege), February 7.

Death from Use of Peroxid of Hydrogen. C. Moreau.—The peroxid had been applied to an amputation wound. Its action on the catgut used for the ligatures caused them to come untied, and the occluding clots became disorganized, entailing secondary hemorrhage, with a fatal result.

Presse Med. (Paris), January 26 and February 20.

Uremic Icterus. A. Delteil.—A case of severe icterus is described which presented all the symptoms of uremic coma in addition to the icteric manifestations, a hepatonephritis, confirmed by the autopsy. The icterus evidently had been grafted on a preceding nephropathy which enhanced the gravity of the prognosis.

Agglutination of the Pneumococcus. V. Griffon.—The characteristic sero-reaction of the pneumococcus is most marked with cocci derived from the patient. Tests with 186 subjects revealed the participation of the pneumococcus in a number of cases in which its presence was unsuspected. The cocci agglutinate in lumps, then resemble fragments of pseudomembrane and, finally, form in the shape of a cup. The test requires 1 to 2 c.c. of serum.

February 20.

Sterilization of Cocain. T. Tuffier.—There are three methods of sterilizing cocain hydrochlorate, all of which are absolutely reliable and do not alter the essential properties of the drug. Tyndall's is the first, and most convenient for certain conditions. The second method is to heat the cocain in a water-bath or the autoclave to 120 C., in a fused tube or plugged vessel. The solution does not undergo any decomposition, and the variation in the light-rotating power is too insignificant to interfere in the least with its action. The third and usually the most convenient method does not require heat. It was devised by Roux and is merely sterilization by filtration through a Chamberland filter. The Chamberland porcelain hollow candle is supported by cotton in the neck of an ordinary test-tube. The solution of cocain is poured into the candle which is plugged with cotton. As the fluid filters through into the test-tube it is absolutely sterile. The only precaution necessary is to throw away the fluid first filtered—two or three times the contents of the candle—to allow the walls to become saturated. In all these processes a 2 per cent. solution is used and the light-rotating power does not vary from the standard—.72 degrees at 10 C. Extreme precautions are necessary to obtain a pure article.

Semaine Medicale (Paris), January 23 and February 20.

Localized Pain in Thorax a Sign of Perforation of Stomach in Peritonitis. J. L. Faure.—Two typical cases are related in detail to demonstrate that acute disturbances of the viscera below the diaphragm, particularly perforation of the stomach, are accompanied by a sharp pain in the thorax, in the shoulder, or between or just below the scapulæ. In generalized peritonitis the determination of perforation of the stomach is of the greatest importance and, consequently, careful inquiry should be made for this thoracic pain in or between the shoulders, whether it existed at the commencement of the trouble, etc. If noted, it is almost pathognomonic of a perforation of the stomach or adjacent organ, and the abdominal incision should be made in the epigastric region.

Identity of Germ Causing Vaccination and Variola. M. Funck.—The author presents arguments to prove that vaccination is not a microbian disease, but that it is caused by a protozoon which is readily recognized in the vaccination as also in the variolous pustules. Inoculation of this protozoon derived from either source produces all the classic symptoms of vaccination and protects animals against further inoculations. Vaccination is therefore merely an attenuated form of variola, and the immunization conferred by it forms no exception to the general laws of specific immunity. The sporozoa were first described by Pfeiffer.

Increase of Hyperchlorhydria by Opium. R. Lepine.—Recent experimental research, reported by various writers, has shown that opium increases the secretion of hydrochloric acid, probably by central excitation, and consequently that it exaggerates the pains in hyperchlorhydria. This does not preclude the use of opium in case of carcinoma of the stomach, as there is no hypersecretion under these circumstances.

Artificial Burns in Treatment of Erysipelas. S. Z. Rabinovitch.—During the last thirteen years the author has treated more than 200 patients by this method, with no deaths and no recurrences. He applies a moist gauze compress to the erysipelatous patch. A wad of cotton dipped in alcohol is placed on a metal plate, held with forceps, and the alcohol is ignited. The flame is then passed over the moist compress again and again as long as the patient can bear it. This maneuver is repeated nine to twelve times a day in three or four sittings. The superficial burn that results soon heals; the heat destroys the streptococci and the steam causes intense local leucocytosis.

Mixed Cocain-Ether Anesthesia. Jaboulay.—A subcutaneous injection of 1 c.c. of a 2.5 per cent. solution of cocain, just before general ether anesthesia, enables profound anesthesia to be rapidly produced with a minimum of ether.

Archiv f. Exp. Path. (Leipsic). February.

Compensation of Mitral Defects. D. Gerhardt.—Experiments made on dogs by the author of this communication confirm the significance of hypertrophy of the right ventricle as the essential factor in the compensation of mitral defects. This compensation, however, entails injurious after-effects by the alterations in the walls of the pulmonary arteries and lungs permanently subjected to such high pressure.

Archiv f. Kinderheilkunde (Stuttgart), XXXI, 1 and 2.

The Scientific Principles of Infant Feeding. A. Monti.—The acidity of cow's milk must be reduced to that of human milk. This can be done with sodium carbonate, which also has the effect of rendering the action of rennet on cow's milk more like that on human milk. The albuminoid elements in the former can be made to approximate those of human milk by diluting with whey instead of water, which also affects the casein and approximates it to human milk. The whey also supplies the fat and the sugar required to render cow's milk more nearly like human milk. In Monti's experience infants have thrived best on milk sterilized by heating to 60 or 70 C. and then cooled to 6 C. and kept at this temperature until used.

Appendicitis in Children. P. Selter.—Vomiting, obstipation, fever and other symptoms vary with different cases. The pulse sometimes shows no alteration, and no tumor can be discovered. Even the local pain is not always present, but there is one symptom that never fails. This is a palpable resistance of the right wall of the pelvis when palpated through the rectum. In 11 of Selter's 28 cases the little patient recovered spontaneously, including 2 or 3 who had had two or three previous attacks.

Archiv f. Klin. Chir. (Berlin), LXII, 2, 3 and 4.

Surgery of the Stomach. G. Kelling.—Among the points established by Kelling in the course of his experimental research on dogs, is that even a small amount of solid food may be followed by perforation after operation on the stomach, and that liquid food is much safer for a time. The rapid evacuation of the stomach that occurs after a gastroenterostomy, is due to the lack of the motor inhibition normally exerted by the filling of the duodenum. Conditions are less favorable for intestinal digestion of albumin and fat after gastro-enterostomy, on account of the absence of the normal excitation of the flow of bile and of bile and pancreatic juice into the stomach, but the neutralization of hydrochloric acid is less perfect than when it has to pass the entire length of the duodenum. Consequently the loop for the anastomosis should be selected as near the stomach as possible. This and the other disadvantages of gastroenterostomy become compensated in time if the organism has sufficient recuperative power. Hence the operation should not be delayed until the system is exhausted by the lesion.

Statistics of Sacral Extirpation of Carcinoma of the Rectum. W. Prutz.—The mortality in 542 cases collected by Prutz has been 115, or 21.2 per cent. He shows that Pichler's reports of a mortality of 14.3 per cent. in 563 operations are erroneous, as he included operations for other lesions than malignant tumors.

No. 3.

New Method of Removing the Seminal Vesicles and Vas Deferens. H. H. Young.—The operation by the method described is very simple and comparatively devoid of danger. Two cases are reported. After catheterization of the ureters, a linear median incision is made, with a short transverse incision at the top just above the umbilicus. A surprisingly good view of the field of operation is afforded by this incision. The bladder is opened in case of suspected disease, the ureters catheterized, and the peritoneum detached from the posterior surface of the bladder wall. The vesicles and vas are isolated in the direction toward the internal ring. The upper portion of the prostate is then incised transversely. The testicle is taken out of the scrotum by an inguinal median incision, the spermatic vein ligated and the vas deferens severed. The rest of the vas can then be drawn into the abdominal cavity, and the testicle, vas and seminal vesicle are then easily removed. This route is much simpler and allows more radical operation than the sacral. The vesicle, and with it a circumscribed portion of the bladder, can be extirpated through a single incision and at one sitting.

Conservative Operations for Renal Retention. C. Fenger.—Kuester, Fenger and Bazy were appointed to present this subject at the recent International Medical Congress, in the section of urinary surgery. The thirty cases on record of conservative operations for renal retention from a stricture, valve-formation or spur in the ureter, are reviewed and tabulated in Fenger's report. They include ten personal cases; no other surgeon had a record of more than three at the time the tables were compiled. The stricture or valve-formation was found at the exit of the ureter in 26 cases, and below the renal pelvis in 3. Israel's was the only case cured by pyeloplication alone. The three deaths that occurred can not be ascribed to the operation in any case, as these conservative operations are simple and reasonably safe. Good functional results were obtained in 22 cases, that is, in 73 per cent. Recurrence of the obstruction and consequent retention compelled nephrectomy later in 2 of Fenger's cases. An obstruction at the pelvic orifice of the ureter may be treated by a transpelvic plastic operation or an extrapelvic incision, plastic operation and pyeloplication. Fenger prefers the extrapelvic incision for small cystonephrotic sacs, but a transpelvic plastic operation is necessary for a large sac, on account of the difficulty of reaching the ureter from outside the pelvis. In 2 of the 9 cases thus operated on, obliteration followed later. Six cases were treated by resection and reimplantation of the ureter. The results were gratifying in the 4 in which the operation was fully completed. The operation was extrapelvic in 11 cases, and proved successful in all but 1; this was a case of remittent, infected cystonephrosis in a small floating kidney. The stricture was below the pelvic orifice of the ureter. Inflammation persisted and the kidney was removed a year later.

No. 4.

Protheses for Gastro-Intestinal Anastomosis. G. Kelling.—The button should be made of absorbable material, but at the same time it must not be digested by the alimentary juices. To meet these contradictory indications, Kelling has devised a button in one piece, made of decalcified bone or ivory. To protect it from the digestive juices it is coated with rubber, except in the wide groove on the outside, in which the intestine is tied. A ring of rubber fits into a shallow groove at one end of the button. After the intestine has been sutured in place in the wide groove the rubber ring is slipped out of the shallow into the wide groove, where it presses the intestine firmly against the button. As the intestine becomes necrotic the rubber ring takes its place on the button, but does not completely fill the groove and the digestive juices commence to work on the unprotected substance of the button. Tests on large dogs have been eminently satisfactory in regard to the advantages of the new button. The same principle is applied to a wooden button for suturing the colon after resection. The sutured portion of the intestine fits in a groove, folded back on itself as in an invagination, and the ring fits on the fold. Its pressure hastens necrosis of the part. In a cholecysto-enterostomy, for instance, Kelling has derived great benefit from the employment of two small, strong metal plates with rounded edges, 1½ by ¼ inches in size, with a hole at each end. A rubber thread is passed through the holes in each plate and one is introduced through a small incision in each end of the loop. By drawing the thread tight the flat surfaces of the two places are coaptated. The plates were released by the necrosis of the tissues between them, and evacuated the fifth to the eleventh day in the tests on dogs.

Means of Occluding the Stomach in Resection. G. Kelling.—Two strips of decalcified bone or ivory, with eight holes in each, are applied on each side of the stomach, above the part to be resected. They should be as long as the stomach is wide at the spot. They are then laced together through the stomach walls with a rubber thread which hermetically closes the organ when it is drawn tight. The strips have been applied in four operations on dogs, with brilliant success. In two dogs not killed until seven and nine days had elapsed, the strips had completely disappeared. [This suggestion recalls the method of hemostasis used on the liver in the operation to separate the Brazilian xiphopagus last year.—Ed.]

Retrograde Sounding of Strictures of the Esophagus. H. Alapy.—All attempts to pass a sound through the double cicatricial stricture proved unavailing in the case reported. Gastrostomy was done five months after the trauma, but efforts to penetrate the stricture from the stomach also failed until an elastic French bougie—No. 15.—olive-tipped, was inserted as far as the stricture in the cardia. A No. 20 silk catheter was then slipped on over the bougie to the stricture and the bougie withdrawn. A fine urethral bougie was then inserted through the catheter and this was finally worked through the stricture into the mouth. By this combination of bougie, catheter and urethral bougie false routes are avoided.

Centralblatt f. Chir. (Leipsic), February 23.

Absence of Sensibility in Abdominal Cavity. K. G. Lennander.—Clinical experiences are related in this communication which indicate that the stomach, intestines and mesentery, the gall-bladder, visceral peritoneum, kidneys and liver have no nerves of sensibility to pain, contact, warmth or cold. On the other hand, the parietal peritoneum is richly supplied with pain nerves. The healthy individual has no nerve-knowledge of the processes of digestion transpiring within him, nor of the functional activity of kidneys or liver. Ulcerations of the alimentary canal may exist without causing pain, and likewise calculi in the biliary passages. The only intimation we have of even strong peristaltic movements is the rumbling of gases. The cause of colic pains is the stretching of the parietal peritoneum in consequence of the acute distention of some portion of the intestines. Affections in the alimentary canal are not accompanied with pain until the parietal peritoneum becomes more or less involved, and adhesions form. In all cases of pelvic and generalized peritonitis palpation from the rectum and vagina is of the greatest importance, as the parietal peritoneum in the small pelvis can thus be directly investigated. These facts are important for abdominal surgery. The incision should be longer than usually made at present to avoid painful traction on the parietal peritoneum. By this means it is not necessary to have the anesthesia so profound, and the anesthetic can be suspended when the manipulations are restricted to the insensible viscera.

Centralblatt f. Gyn. (Leipsic), January 19, February 2 and 9.

Treatment of Backward Displacement of the Gravid Uterus. L. Seeligmann.—The incarcerated uterus was gradually forced into a slanting position with its longitudinal axis parallel with the second oblique diameter of the pelvis, by traction on the portio and gentle pressure on the fundus in the opposite direction. A colpeurynter was then placed under the fundus and, as it filled, the uterus gradually resumed its normal position, the patient reclining on the side, with the pelvis elevated, for two and a half hours. Four cases have been successfully treated in this way by the author.

Protection of the Perineum During Delivery. J. Hofbauer.—As the head is passing the vulva, when the posterior angle of the anterior fontanelle is just beginning to emerge, Hofbauer gives the head a twist of 40 degrees at most to right or left. This brings the soft fontanelle opposite the perineum, and the danger of laceration is almost sure to be averted.

Healing Processes in Tubercular Affections. A. O. Lindfors.—Retrogressive atrophy is the essential element in the healing of tubercular lesions, Lindfors is convinced. He has observed a case in which the atrophy due to the menopause arrested the tubercular process in one Fallopian tube, while the tuberculosis continued its progressive course in the other tube, in which the nutrition had been maintained by a growing cyst. He suggests that ligature of the vessels sufficient to cause atrophy, but not necrosis, may prove a valuable aid in the cure of tubercular processes.

Extirpation of Right Ovary Through Left Inguinal Incision. L. Remprecht.—Inguinal hernia prevented an incision on the side of the lesion. The removal of the ovary and cyst was comparatively simple, although the success of the operation was jeopardized by the abnormal shortness of the infundibulo-pelvic ligament.

Massage in Gynecology. R. Olshausen.—The only conditions in which massage has a favorable influence in gynecology are in case of a torpid exudation, all inflammatory symptoms long past, and then only when favorably located, with merely the abdominal wall between it and the fingers. Massage is applicable to tubal tumors only when they are hydrosalpingitic and it is possible to obtain the elimination of the fluid through the uterus. Peritoneal adhesions, hematocele, misplacements of vagina or uterus should not be massaged, although it is possible that they may benefit indirectly from massage of a surrounding exudate.

Deutsche Med. Wochenschrift (Leipsic), February 21.

Combined Chloroform and Oxygen Narcosis. Wohlgemuth.—A stream of oxygen into which chloroform is introduced a drop at a time is brought into the mask, excluding ordinary air. Wohlgemuth asserts that the effect is to induce a perfect narcosis "which will banish chloroform death from the world." In 140 cases in which he has applied this improved technique the pulse remained absolutely normal all the time, always full and slow, even in anemic patients in profound narcosis. There were never any disturbances in breathing, nor cyanosis; the color of the face was normal, even the lips were bright red in all cases. The patients awoke rapidly, and with a clear consciousness in five to ten minutes. Other surgeons are testing the method so that a sufficient number of anesthesias will be attained ere long to afford a basis for comparison with other methods of narcosis.

Tuberculosis Hospitals. G. Kluge.—During the last four years Kluge has seen thirty healthy children become affected with tuberculosis in some form while a consumptive in their homes was disregarding all hygienic regulations to prevent infection of others. He urges legislation to enforce the removal of such inconsiderate sources of infection to some asylum, to protect the children in the home. Wilful disregard of the measures necessary to prevent injury to others should entail removal and isolation as inevitably as in the case of the insane.

Pflueger's Archiv f. Phys. (Bonn), January.

The Iodin in Iodothyrin. E. V. Cyon.—Thyreoglobulin is evidently the albuminoid substance that contains the iodothyrin complex in its molecule. The antagonism between the physiologic action of iodothyrin and of iodin on the vascular system is due to the iodin in some other combination in the thyroid gland. None of the other products of the gland possess the same properties as the iodothyrin, even although they may contain iodin.

Wiener Klin. Wochenschrift, February 21.

Cure of Incontinence by Paraffin. Kapsammer.—Three cases of incontinence of urine in women, due to laceration of the vagina and urethra or chronic cystitis, or dating from childhood, are reported by Kapsammer as cured by one or two injections of white vaselin—paraffin—6 c.c. at a time. The aim is to produce an artificial dam, similar to the prostate in man, around the urethral orifice. In Pfannenstiel's unfortunate experience the vaselin was injected in a ring, instead of in one spot, and he used a combination with a melting point of 45 C. Gersuny, the originator of the method, warns against using a vaselin with a melting point above 35 to 40 C. He injects it at a temperature such that it emerges from the needle in a worm, not in drops, and he always inserts the needle at the same spot, waiting a week between the injections. One other unpublished instance of embolism of the lungs has occurred in consequence of the injections, in the experience of a Vienna practitioner, but Gersuny states that he has never noted any inconveniences from the paraffin, in a constantly widening experience, even when the injections were made in the periproctal region or the orbit.

Gazzetta Degli Osp. (Milan), February 10 and 17.

Aspiration of Fluid in Acute Articular Rheumatism. F. Zagato.—The agonizing pains in the knee, in the course of acute rheumatic polyarthritis, were relieved instantaneously by inserting the small-sized needle of a Pravaz syringe and aspirating the fluid distending the capsule—about 60 c.c. The pains did not reappear, but the other knee required the same intervention in a few days. The operation was concluded by injecting a syringeful of a 2 per cent. solution of carbolic acid.

Electrotherapy in Exophthalmic Goiter. A. Lamari.—A severe case of exophthalmic goiter is described as clinically cured after forty applications of electricity to the vagus and cervical sympathetic.

St. Petersburg Med. Woch., February 16.

Belladonna in Intestinal Obstruction. E. Moritz.—For many years Moritz has been proclaiming the advantages to be derived from belladonna in the treatment of intestinal obstruction from any cause, and its superiority to all other medicinal measures. He administers by the mouth a pill of 1.5 mg of extract of belladonna, every four to six hours, until flatus passes. The first symptoms of transient intoxication appear after six to ten doses; dryness in the throat, agitation, sometimes delirium, but just before this point is reached the intestinal contents are evacuated, with no painful peristalsis nor vomiting. This treatment is applicable to all varieties of intestinal occlusion; can never do harm; sometimes removes the obstruction without further measures; untwists a slight volvulus; almost always relieves, and renders the conditions more favorable for operation if this becomes necessary. If fever persists after flatus passes, operation should not be delayed. He rejects atropin as too dangerous, but six physicians reported, last year in the *Muench. Med. Woch.* extremely favorable results obtained in severe cases of ileus by the subcutaneous injection of 1 to 5 mg. of atropin. In one case the patient was 80 years of age and recovered after injection of 1 and 3 mg. of atropin. Another patient died; the ileus in this case was consecutive to an operation on the fourth day of strangulated femoral hernia, and the physician is inclined to believe that a second injection might have saved the patient. [The last number of the same journal, February 19, describes another case in which the ileus must have been due to volvulus, as there had been no preceding constipation and the localization of the pain was in the left iliac region. The dose of 1 mg. had no effect, nor 1.5 mg. a few hours later. The fecal vomiting continued, but injection of 3 mg. the next day was followed in twenty minutes by flatus and copious evacuations. All traces of the slight intoxication from the atropin had passed away in twenty-four hours.—Ed.]

Queries and Minor Notes.

RECIPROCITY CONCERNING LICENSE.

Fairmount, Ind., Feb. 18, 1901.

To the Editor:—Can you inform me where I can obtain a copy of Dr. Paul Amberg's article entitled, "Present Status of Interstate Reciprocity Concerning License to Practice Medicine?"

A. H.

Ans.—In the *Medical News*, Nov. 3, 1900, a copy of which can be obtained through Lea Brothers & Co., New York City.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Feb. 21 to 27, 1901, inclusive:

George E. Bushnell, major and surgeon, U. S. A., sick leave of absence extended.

Marshall M. Cloud, lieutenant and asst.-Surgeon, U. S. A., sick leave of absence extended.

Francis G. Engelhardt, acting asst.-surgeon, from San Francisco, Cal., to Syracuse, N. Y., reporting by letter, on arrival, to the Surgeon-General for annulment of contract.

Joseph M. Heller, major and surgeon, Vols., to Fort Myer, Va., for duty with the squadron of the 5th Cavalry now under orders for the Philippines.

Deane C. Howard, captain and asst.-surgeon, U. S. A., leave of absence granted.

George J. Newgarden, captain and asst.-surgeon, U. S. A., sick leave of absence extended.

Joseph C. Reifsnyder, acting asst-surgeon, member of a board at West Point, N. Y., to examine candidates for admission to the U. S. Military Academy, vice Lieut. Franklin M. Kemp, asst.-surgeon, U. S. A., relieved.

Frederick P. Reynolds, major and surgeon, Vols., relieved from further duty in the Division of the Philippines and assigned to duty at the U. S. General Hospital, Washington Barracks, D. C.

Ira A. Shimer, lieutenant and asst.-surgeon, Vols., from the Department of Cuba to duty at Fort McHenry, Md.

Alexander N. Stark, major and surgeon, Vols., from the Department of Cuba to duty at Fort McHenry, Md.

Roy A. Wilson, acting asst.-surgeon, from Fort Totten, N. Y., to Fort Ethan Allen, Vt., to accompany the squadron of the 5th Cavalry to be sent from that post to Fort Grant, Ariz.; thereafter to return to his proper station.

Robert H. Zauner, acting asst.-surgeon, from Fort Du Pont, Del., to Columbus Barracks, Ohio, for temporary duty.

Navy Changes.

Changes in the Medical Corps of the Navy for week ended March 2, 1901:

Surgeon G. Pickrell, detached from the Cavite Naval Station, and ordered to the Mare Island Navy Yard.

Asst.-Surgeon J. C. Thompson, detached from the *Solace*, and ordered home to wait orders.

Surgeon A. R. Wentworth, detached from the *Independence*, and ordered to the *Solace*.

Surgeon F. J. B. Corderio, detached from the *New Orleans*, and ordered home via the *Buffalo*.

Surgeon C. F. Stokes, detached from the *Buffalo*, and ordered to the *New Orleans*.

Medical Inspector F. Rogers, detached from recruiting duty and ordered to the Asiatic Station, as fleet surgeon.

Medical Inspector R. C. Persons, detached from duty as fleet surgeon of the Asiatic Station, and home to wait orders.

Surgeon W. H. Rush, retired, detached from the Pensacola Navy Yard, and ordered home.

Health Reports.

The following cases of smallpox, yellow fever and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended March 2, 1901:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Feb. 16-23, 1 death.

California: Los Angeles, Feb. 9-16, 1 case.

District of Columbia: Washington, Feb. 2-23, 12 cases.

Florida: Jacksonville, Feb. 16-23, 3 cases.

Illinois: Chicago, Feb. 16-23, 10 cases.

Indiana: Delaware County, Feb. 2, 1 case.

Kansas: Lawrence, Feb. 8-16, 1 case; Wichita, Feb. 16-23, 8 cases.

Kentucky: Lexington, Feb. 8-23, 3 cases.

Louisiana: New Orleans, Feb. 16-23, 14 cases, 3 deaths; Shreveport, Feb. 16-23, 2 cases.

Maryland Baltimore, Feb. 16-23, 1 case.

Michigan: West Bay City, Feb. 8-23, 2 cases.

Minnesota: Minneapolis, Feb. 8-23, 15 cases; Winona, Feb. 16-23, 13 cases.

Missouri: St. Joseph, Jan. 1-31, 34 cases, 1 death.

Nebraska: Omaha, Feb. 8-23, 12 cases.

New Hampshire: Manchester, Feb. 16-23, 30 cases.

New Jersey: Newark, Feb. 8-26, 3 cases.

New York: New York City, Feb. 16-23, 43 cases, 9 deaths.

Ohio: Ashtabula, Feb. 16-23, 3 cases; Cincinnati, Feb. 15-22, 3 cases; Cleveland, Feb. 16-23, 48 cases.

Pennsylvania: Erie, Feb. 16-23, 1 case; Pittsburg, Feb. 16-23, 3 cases; Steelton, Feb. 16-23, 1 case.

South Carolina: Greenville, Feb. 16-23, 2 cases.

Tennessee: Memphis, Feb. 16-23, 21 cases; Nashville, Feb. 16-23, 6 cases.

Texas: Galveston, to Feb. 16, 123 cases.

Utah: Salt Lake City, Feb. 8-23, 46 cases, 1 death.

West Virginia: Huntington, Feb. 16-23, 1 case.

SMALLPOX—FOREIGN AND INSULAR.

Austria: Prague, Jan. 26-Feb. 9, 17 cases.

Belgium: Antwerp, Jan. 26-Feb. 2, 1 case; Ghent, Jan. 19-26, 1 death.

Brazil: Bahia, Jan. 19-26, 3 cases; Pernambuco, Dec. 17-Jan 15, 62 deaths; Rio de Janeiro, Dec. 16-Jan. 15, 39 deaths.

Ceylon: Colombo, Jan. 6-12, 1 case, 1 death.

Ecuador: Guayaquil, Jan. 8-26, 11 deaths.

France: Paris, Jan. 16-Feb. 9, 32 deaths.

England: Bradford, Feb. 2-9, 2 cases; Liverpool, Feb. 2-9, 1 case; London, Jan. 26-Feb. 9, 4 cases; Newcastle on Tyne, Jan. 26-Feb. 2, 7 cases, 1 death.

India: Bombay, Jan. 15-27, 9 deaths; Calcutta, Jan. 12-26, 186 deaths; Karachi, Jan. 13-27, 22 cases, 14 deaths; Madras, Jan. 15, 6 deaths.

Mexico: City of Mexico, Feb. 1-16, 4 deaths.

Netherlands: Rotterdam, Feb. 8-16, 1 case.

Porto Rico: Ponce, Feb. 1-10, 32 cases.

Russia: Moscow, Jan 19-Feb. 2, 17 cases, 2 deaths; Odessa, Jan. 26-Feb. 9, 35 cases, 13 deaths; St. Petersburg, Jan. 26-Feb. 2, 1 case; Warsaw, Jan. 19-26, 12 deaths.

Scotland: Dundee, Jan. 26-Feb. 9, 17 cases; Glasgow, Feb. 8-15, 10 deaths.

Straits Settlements: Singapore, Dec. 29-Jan. 12, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, Dec. 8-Jan. 15, 10 deaths.

Cuba: Havana, Feb. 8-16, 2 cases, 2 deaths.

Mexico: Vera Cruz, Feb. 8-15, 1 death.

PLAGUE.

Africa: Cape Town, Feb. 8, 2 cases.

India: Bombay, Jan. 16-29, 837 deaths; Calcutta, Jan. 12-26, 89 deaths; Madras, Jan. 19-26, 1 death.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

ELBOW FRACTURES AND THE X-RAY.[*]

W. W. GRANT, M.D.
Surgeon, C. R. I. & P. R. R., and Consulting Surgeon, U. P. Ry.
DENVER, COLO.

There are, no doubt, those who think we have reached the highest excellence in the treatment of most fractures, but none who are familiar with the treatment and results of elbow fractures and *x*-ray disclosures will be deluded by the brilliant achievements of this surgical age. There are still more things in surgery and medicine than are dreamt of in our philosophy. My purpose is to present for consideration some mooted questions in the treatment of these elbow injuries and the importance of the facts disclosed by the *x*-ray in the future treatment of fractures.

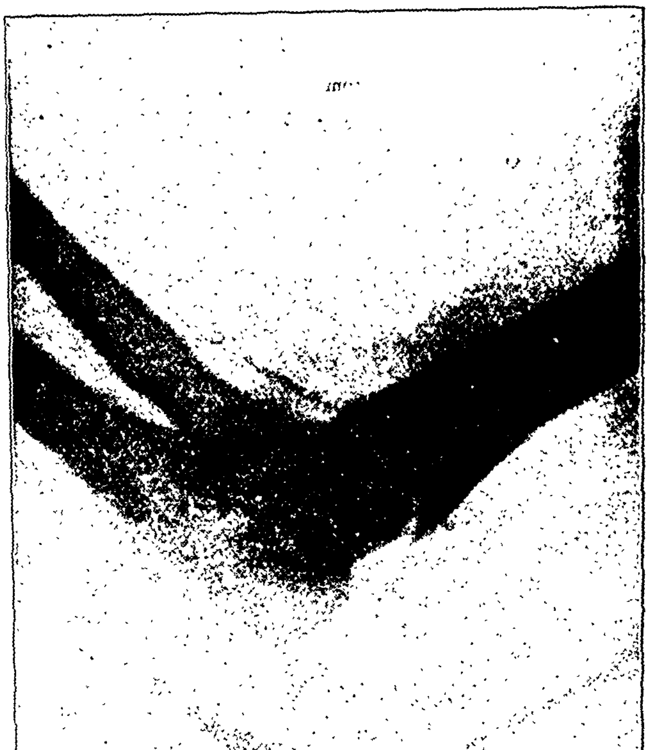
Allis, years ago, called attention to the importance of maintaining the normal angle of the humerus and ulna in the treatment of fractures of the lower end of the humerus, because of its influence on the carrying function of the arm. He treats the arm in extension because he believes it best maintains the fragments and the normal angle. This angle is greater than many suspect. With the arm extended in supination, a line drawn from the head of the humerus between the tuberosities will meet a transverse line through the carpus two inches inside of the styloid process of the ulna, which is the measure of the outward deviation of the forearm. If, in the adjustment of the fragments, the articular surfaces do not conform to this angle, the carrying power will be diminished. In any position with imperfect coaptation of fragments anchylosis is more certain. The assertion of Stimson that upward displacement of the internal condyle one-fourth of an inch will destroy the normal angle of deflection at the elbow is in itself a strong plea for more radical and reliable treatment in many of these cases

The maintenance of perfect coaptation of the fragments is not only difficult, but almost impossible without cutting down on the fragments and fixing them by wire or screws or clamp. The great majority of surgeons treat fractures of the condyles and supracondyloid with the arm at a right or acute angle. A few, conspicuously Allis and Roberts, prefer the arm in complete extension, believing that anchylosis is not so common. I have not treated these fractures in extension nor by operation, except compound, but I have seen more cases of anchylosis in this than in the flexed position.

Unlike most fractures, a perfectly accurate adjustment and coaptation of the fragments seem necessary to a perfect functional result. This object is so difficult of attainment that if more satisfactory and perfect results can be safely obtained by operative means the time has come when it should be more generally adopted.

I have two cases, with skiagraphs, which I desire to report as pertinent to the discussion.

Mrs. M., aged 65, fell on the sidewalk in May, 1898, producing a supracondyloid fracture of the humerus. The line of fracture, as shown by the skiagraph, traversed the upper border of the coronoid and olecranon fossæ. It did not seem difficult to replace and to maintain the fragments. The two skiagrams taken on the second and seventh day show that the fragments were not retained in as good position as desired. There was splintering of the upper fragment posteriorly. The fragments were adjusted three times and the arm kept at a right angle in long posterior and short anterior splints. While flexion and extension are not perfect, the functional result is good. The fact that she can feed herself and dress her hair with ease is sufficient attestation of the fact. She experiences no discomfort nor inconvenience in its use. It is difficult to prevent rotation of the lower fragment in these cases.



Case 1.—Supracondyloid fracture of right humerus.

Except with a laboring person, the evil of the gunstock position as to the impairment of the carrying function is much exaggerated.

Union, with as much overlapping as indicated, is a mechanical impediment to perfect flexion. Cheyne and

---

[*] Read at the Annual Meeting of the American Academy of Railway Surgeons, held at St. Paul, Minn., Sept. 5 and 6, 1900.

George J. Newgarden, captain and asst.-surgeon, U. S. A., sick leave of absence extended.

Joseph C. Reifsnyder, acting asst-surgeon, member of a board at West Point, N. Y., to examine candidates for admission to the U. S. Military Academy, vice Lieut. Franklin M. Kemp, asst.-surgeon, U. S. A., relieved.

Frederick P. Reynolds, major and surgeon, Vols., relieved from further duty in the Division of the Philippines and assigned to duty at the U. S. General Hospital, Washington Barracks, D. C.

Ira A. Shimer, lieutenant and asst.-surgeon, Vols., from the Department of Cuba to duty at Fort McHenry, Md.

Alexander N. Stark, major and surgeon, Vols., from the Department of Cuba to duty at Fort McHenry, Md.

Roy A. Wilson, acting asst.-surgeon, from Fort Totten, N. Y., to Fort Ethan Allen, Vt., to accompany the squadron of the 5th Cavalry to be sent from that post to Fort Grant, Ariz.; thereafter to return to his proper station.

Robert H. Zauner, acting asst.-surgeon, from Fort Du Pont, Del., to Columbus Barracks, Ohio, for temporary duty.

Navy Changes.

Changes in the Medical Corps of the Navy for week ended March 2, 1901:

Surgeon G. Pickrell, detached from the Cavite Naval Station, and ordered to the Mare Island Navy Yard.

Asst.-Surgeon J. C. Thompson, detached from the *Solace*, and ordered home to wait orders.

Surgeon A. R. Wentworth, detached from the *Independence*, and ordered to the *Solace*.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one *dollar are acceptable.* Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

Original Articles.

ELBOW FRACTURES AND THE X-RAY.*

W. W. GRANT, M.D.

Surgeon, C. R. I. & P. R. R., and Consulting Surgeon, U. P. Ry.

DENVER, COLO.

There are, no doubt, those who think we have reached the highest excellence in the treatment of most fractures, but none who are familiar with the treatment and results of elbow fractures and *x*-ray disclosures will be deluded by the brilliant achievements of this surgical age. There are still more things in surgery and medicine than are dreamt of in our philosophy. My purpose is to present for consideration some mooted questions in the treatment of these elbow injuries and the importance of the facts disclosed by the *x*-ray in the future treatment of fractures.

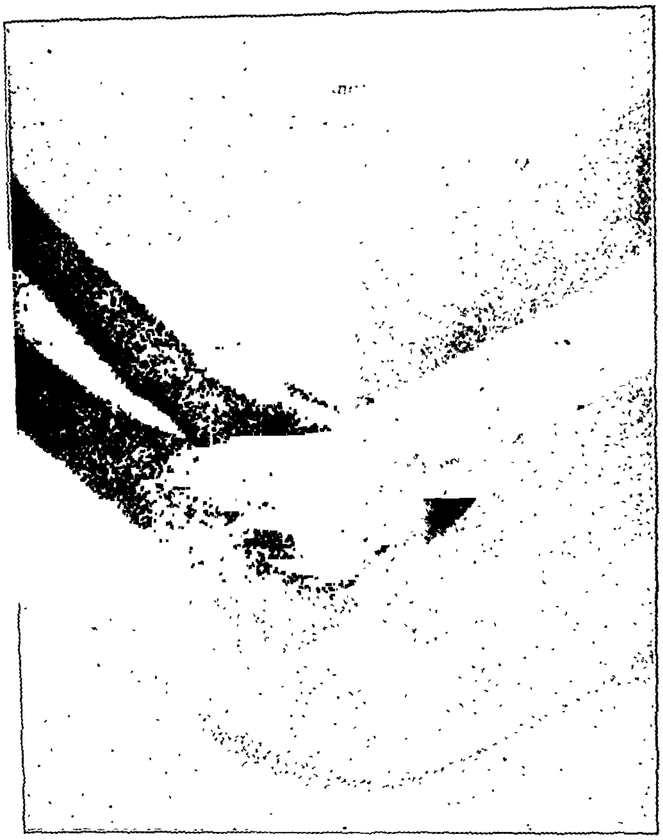
Allis, years ago, called attention to the importance of maintaining the normal angle of the humerus and ulna in the treatment of fractures of the lower end of the humerus, because of its influence on the carrying function of the arm. He treats the arm in extension because he believes it best maintains the fragments and the normal angle. This angle is greater than many suspect. With the arm extended in supination, a line drawn from the head of the humerus between the tuberosities will meet a transverse line through the carpus two inches inside of the styloid process of the ulna. which is the measure of the outward deviation of the forearm. If, in the adjustment of the fragments, the articular surfaces do not conform to this angle, the carrying power will be diminished. In any position with imperfect coaptation of fragments anchylosis is more certain. The assertion of Stimson that upward displacement of the internal condyle one-fourth of an inch will destroy the normal angle of deflection at the elbow is in itself a strong plea for more radical and reliable treatment in many of these cases

The maintenance of perfect coaptation of the fragments is not only difficult, but almost impossible without cutting down on the fragments and fixing them by wire or screws or clamp. The great majority of surgeons treat fractures of the condyles and supracondyloid with the arm at a right or acute angle. A few, conspicuously Allis and Roberts, prefer the arm in complete extension, believing that anchylosis is not so common. I have not treated these fractures in extension nor by operation, except compound, but I have seen more cases of anchylosis in this than in the flexed position.

Unlike most fractures, a perfectly accurate adjustment and coaptation of the fragments seem necessary to a perfect functional result. This object is so difficult of attainment that if more satisfactory and perfect results can be safely obtained by operative means the time has come when it should be more generally adopted.

I have two cases, with skiagraphs, which I desire to report as pertinent to the discussion.

Mrs. M., aged 65, fell on the sidewalk in May, 1898, producing a supracondyloid fracture of the humerus. The line of fracture, as shown by the skiagraph, traversed the upper border of the coronoid and olecranon fossæ. It did not seem difficult to replace and to maintain the fragments. The two skiagrams taken on the second and seventh day show that the fragments were not retained in as good position as desired. There was splintering of the upper fragment posteriorly. The fragments were adjusted three times and the arm kept at a *right* angle in long posterior and short anterior splints. While flexion and extension are not perfect, the functional result is good. The fact that she can feed herself and dress her hair with ease is sufficient attestation of the fact. She experiences no discomfort nor inconvenience in its use. It is difficult to prevent rotation of the lower fragment in these cases.



Case 1.—Supracondyloid fracture of right humerus.

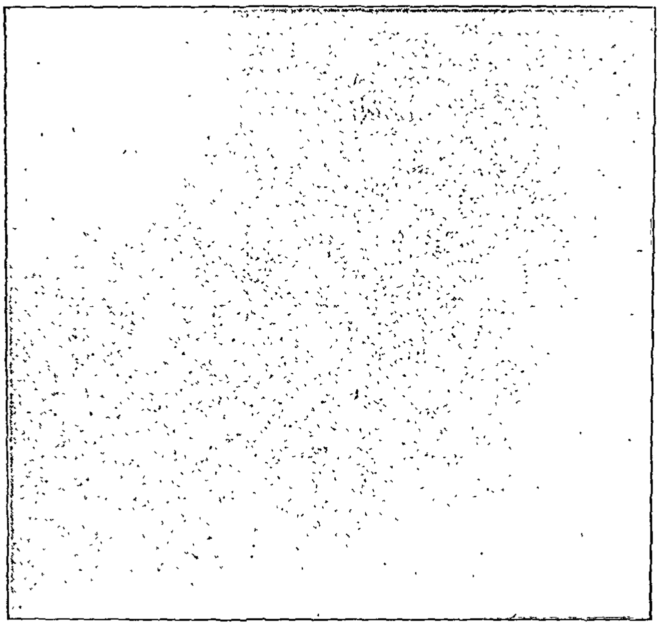
Except with a laboring person, the evil of the gunstock position as to the impairment of the carrying function is much exaggerated.

Union, with as much overlapping as indicated, is a mechanical impediment to perfect flexion. Cheyne and

---

* Read at the Annual *Meeting* of the American Academy of Railway Surgeons, held at St. Paul, Minn., Sept. 5 and 6, 1900.

Burghard suggest that this defect may be overcome by treating the arm in acute flexion with a compress over the upper fragment. As most surgeons believe that the action of triceps and brachialis influences the position of the lower fragment, I may suggest that as no position will relax both, tenotomy is appropriate and sometimes useful.



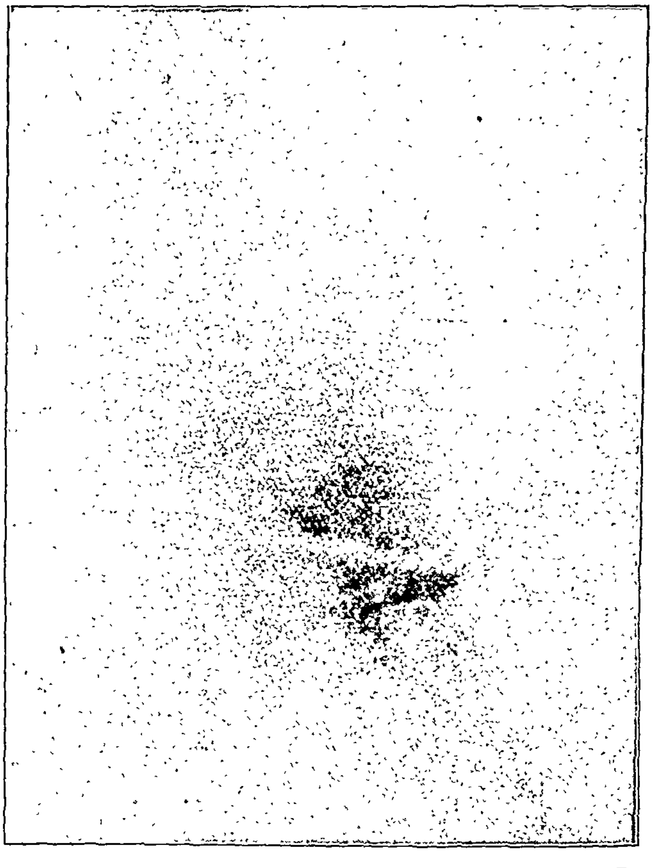
Case 1.—Mrs. M., October, 1900, three years and three months after injury. Arm looks well. Considerable antero-posterior thickening due to splintering, callus and undue prominence of upper fragment anteriorly with rotation of trochlea.

Case 2.—M. M. Y., aged 40, a brakeman, was, on June 21, 1900, on top of a refrigerator car with his legs in the ice chamber when the car went off the track and, throwing him against the side of the ice chamber, fractured the internal condyle of the left humerus, involving the joint freely. I saw him twelve hours after, when the parts were greatly swollen, making a satisfactory examination difficult even under chloroform. Four days later a skiagraph by Dr. Stover showed the fragments with the condyle displaced upward. The swelling was now much reduced, and under chloroform the fragment was easily adjusted and the arm treated at a right angle throughout. It was examined two or three times a week, but passive motion was not used until the end of the third week when union was quite good. At the end of two months he was engaged in light work and flexion and extension were very good and steadily improving. A skiagraph three months later, September 19, showed good union and excellent position of the fragments.

Case 1.—Mrs. M., October, 1900, three years and three months after injury. Longer exposure to x-ray. Callus not so well shown. Solid union; functional result very good.

Some recent writers maintain that the coaptation of the condyles can only be securely maintained by cutting down on the condyles and wiring or nailing the fragments, and that this is the best method of treatment, while most surgeons would treat them with bandages and splints in flexion, a few in extension.

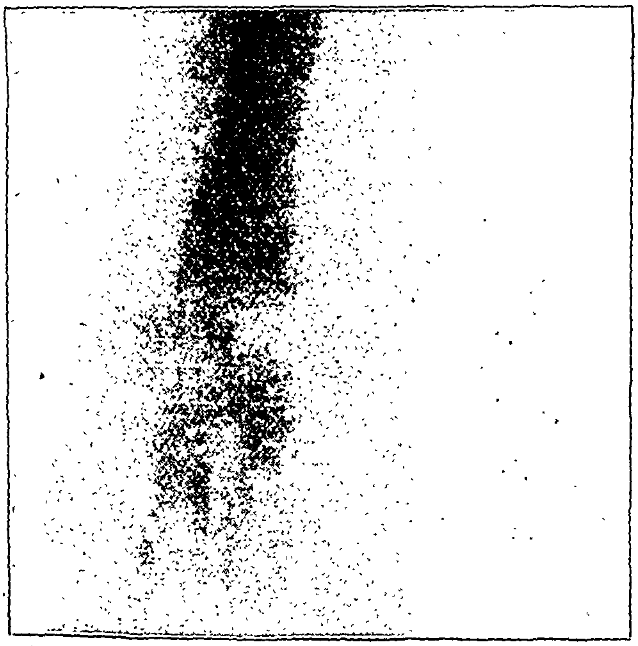
There are some general considerations of special interest that might with propriety be mentioned in this connection as determining general conclusions:



Case 2.—M. M. Y., posterior view June 23, fourth day. Readjusted immediately after.

Anchylosis is due to misplaced fragments, and when in position should not be endangered by manipulation. Rubbing and gentle massage of the muscles may be used in a week. It is important in feeble subjects, but care should be exercised not to disturb the joint and fragments, as rest is the important principle in the treatment of any fracture and of the greatest value in acute joint troubles.

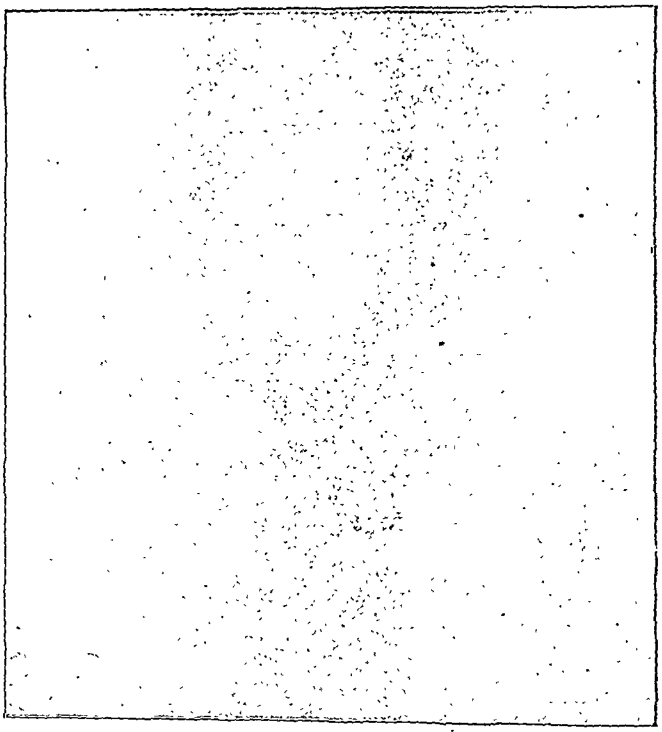
The real status of the x-ray is yet to be determined, though its use in surgery is one of the distinct scientific advances of our time. I fear we are prone to rely too exclusively on instruments of real or supposed demonstrable scientific precision which do not appeal to the exercise of our own analytic judgment and surgical acumen. There is danger that improvements in specialization may dull our sensibilities and, to an unfortunate extent, limit our accomplishments in methods of investigation and diagnosis. In the location of foreign bodies its value is unquestioned. In the diagnosis of fractures its use is not so important nor its benefits so pronounced. In demonstrating the position of the fragments it is more useful, yet often inaccurate, and therefore unreliable, and dangerous to the surgeon because it exaggerates the malposition of the fragments, the deformity and the impairment of the limb. The functional results are much better than the skiagram would indicate as possible. This is well illustrated in the skiagram presented of an oblique fracture of the femur in a child 9 years old. The accident occurred April 21, 1900, by the child falling down a mine shaft. One month later she was placed in my charge, and at that time the skiagraph was taken. Repeated and careful measurements showed that the shortening did not exceed three-fourths of an inch, and this was partly due to the bend or distorted axis of the limb. I call attention to the apparent extreme overlapping of the fragments. The light shadow represents the temporary callus. The distinction is highly important. Imagine the influence of such a picture on a patient or a jury. As the father in this case expressed it in a letter to me: "It was about as bad a jumbled up leg" as he ever saw. It might have been better, but the functional result is good. She was treated by an intelligent young surgeon who noted great difficulty in controlling the child's movements and the position of the limb, though it is quite natural and, to all external appearances, the result is excellent.



Case 2.—M. M. Y., September 19, three months after injury. Good union and position of fragment.

The other skiagraph, made by Stover, of Denver, one year ago, represents an oblique fracture of both the tibia and fibula about the middle. It is the case of a Boston woman who was treated by a Boston surgeon. It is a unique and extremely interesting specimen and appropriate to this discussion. It will be observed that while the tibial fragments are not perfectly adjusted, yet union is good; but the chief interest is in the fibula. The upper end of the lower fragment was undoubtedly driven against the tibia when the accident occurred, was never replaced, and is united to the tibial fragments, while the upper fragment is not in contact with any other, and therefore is ununited. The contour of the leg is perfect and the patient uses it even in dancing with comfort and pleasure. The position looks bad, but I believe it a safe assertion that the fragment could never have been replaced without cutting down on it and adjusting by the application of force.

Such a demonstration is significant. Mr. Lane,[1] of London, maintained, with much plausibility, that muscular action in displacing and preventing the satisfactory adjustment of fractures is greatly overestimated by surgeons: "That spasmodic muscular contraction exerts no appreciable influence on the fragments and may be left out of consideration in the treatment; that at best its opposition to replacement in the early period is only slight and transitory; that the obstacles to perfect adjustment are effusion of blood and inflammatory products about the fragments, and that we are unable to restore the bones to their normal form by means of manipulation and splints." While these remarks are specially applicable to Pott's fracture and to oblique fractures of the long bones, and, I may add, to the lower jaw, it will be a distinct advance when operation is resorted to when the fragments can not be satisfactorily adjusted and maintained by other means. In compound fractures there should be no ground for controversy. In others the question has only excited serious general consideration in reference to fracture of the patella, and the great majority of surgeons prefer nonoperative methods. But if worthy of serious notice concerning a fracture that frequently involves an important joint, what serious objection can be used to its application in fractures which never involve a joint, and where, should infection occur, it is not likely to prove so serious. Infection is the only danger, but with confidence in the established tenets of modern surgery in reference to bacteriology we do not hesitate to expose the abdominal and every other cavity with impunity, and why not broken bones.



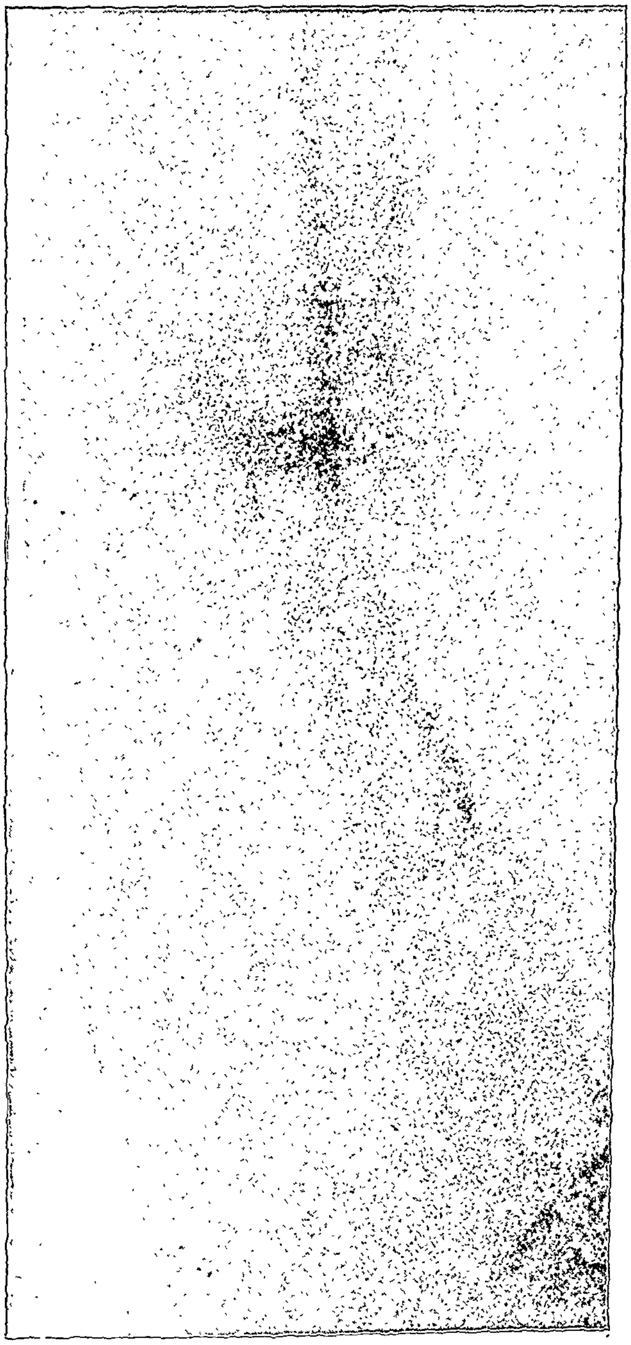
Fracture of both bones of leg. Note symmetry of fleshy outline.

With due allowance for its defects and dangers, the x-ray has made new conditions and imposed new demands and responsibilities on the surgeon. Do not the medicolegal aspects of the question, as well as practical results, indicate the necessity or desirability of more radical methods in the treatment of certain oblique and joint fractures? If both are put on a sounder and safer basis, this must be answered in the affirmative.

---

[1] Lane Lectures, 1897.

The only way to more certainly maintain the accurate coaptation of the fragments is to immobilize them by silver wire, screw, nail or clamp, but only under the most approved aseptic conditions. In the absence of infection the results must be better. This department of surgery has not been met with the courage and skill that has been so manifest in other fields, and it is too important not to receive the serious attention it deserves.



Fracture of Thigh. Posterior View.

Carl Beck[2] says, in reference to skiagraphs, that there are injuries, the correct interpretation of which presupposes, besides thorough anatomic knowledge, the greatest care and a vast amount of experience as to the different modes of delineation in various projection planes.

The greatest diagnostic difficulties are offered by the joints. With a distinct skiagraphic plate, taken under improved scientific conditions, it should, he avers, with expert clinical and anatomic knowledge, be evidence in court.

The *Annals of Surgery* for August contains an elaborate scientific paper by Cotton, of Boston, on the "Pathology of Fractures of Lower End of Radius." In reference to the Roentgen ray, he says: "It may be said in advance that there seems to be no single form of lesion described from any actual specimen which is susceptible of demonstration in the shadow picture that has not been demonstrated in one or more clinical cases; nor has the x-ray discovered any previously undescribed lesion. . . . It needs no argument to show that the x-ray plate, valuable as it is, is in many ways rather an *imperfect record*."

The American Surgical Association, at its last annual meeting, in May, by unanimous vote passed a resolution that the skiagraph is inadmissible as evidence in court, because, being a picture of a shadow and not of the object, it is inaccurate and unreliable.

The only tenable conclusion, it seems to me, is that the skiagraph should never be used as the determining factor in regard to the existence and pathology of fractures, but may be, in honest and capable surgical hands only, used to supplement or confirm opinions reached without it. It must always be a condition that the electrician is equally honest and competent. The illustrations and facts familiar to surgeons show beyond a doubt how unjust and indefensible a conclusion must be, in or out of court, that is based solely or chiefly on the appearances of the skiagraph.

GENERAL BODILY RESISTANCE AS A FACTOR IN NOSE AND THROAT DISEASE.*

FRANK LOUIS STILLMAN, M.D.
COLUMBUS, OHIO.

Good health is sometimes regained after the organism has been long below par, but in these cases there does not seem to be as much surplus to draw on as in those cases in which there is an exuberant vitality—in which, with a heritage of good health to start with, there has been a continued triumph of health and resistance over the encroachments of disease. It is this tendency of repeated small attacks of sickness acting as a drag upon the natural tendency of the body toward health that should be carefully watched by the physician. For example, a cold in the head is not generally considered a very dangerous thing, but frequently recurring colds in the head will lead to lack of resiliency in the parts affected that may gradually lead to chronicity.

The majority of the cases coming under the care of a throat specialist are chronic, and the treatment generally aims to remove the effects of some long-continued morbid action. It is a fact that most chronic affections of the upper respiratory tract are notoriously difficult to cure by medication, either local or general. The great advances in the specialty came when surgical means were perfected whereby good ventilation and drainage could be secured. These improved methods of treatment, which were forwarded greatly by the discovery of cocain, almost revolutionized the practice of the art, and now the percentage of cases that can be relieved is high. Still there are certain classes or stages of these troubles which either are not amenable to surgical treatment or are liable to recurrence—and here is where our wisest forethought has its play.

---

[2] Med. Record, N. Y., Aug. 25, 1900.

* Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Chronologically, at least, heredity has more influence upon bodily resistance than anything else. Evolution teaches us that physical types are transmitted. Sometimes particular family stocks seem to have greater immunity to certain diseases than others. In the case of infectious diseases this might be accounted for by saying that the soil had become exhausted and is not suitable for the growth of certain bacteria. It is like the well-observed fact that yeast will not propagate in well-fermented bread or wine. In ordinary cases it is reasonable to believe that if one's ancestors lived in such an environment as to induce good health in themselves, in all probability their descendants would inherit physiques which would make their bodies more likely to withstand morbific influences. On the other hand, "the sins of the fathers will be visited upon the children," and their omissions and commissions will be evidenced in their descendants by that which we call lessened resistance. Because your great grandfather was fond of a certain brand of wine is the cause of your tendency to sore throat. This is a rather devious course of reasoning, but thus Nature does her work.

We would all choose healthy ancestors if we could, but as that is impossible—except when selecting a family coat of arms—we can do the next best thing and select as suitable an environment as possible; and, after all, this is almost as important as a healthy ancestry. I am not prepared to question the fact that in many of the diseases of the upper respiratory tract the most brilliant results are brought to pass through means almost purely surgical; still, of the great mass of these diseases treated, attention to the patient's environment is the most vital point in giving genuine relief. By environment is meant the sum of the surroundings and conditions. Used in this sense it would include the patient's food, habits and hygiene—in fact everything, other than the patient himself, which has an influence upon the local condition. This would include all extraneous matters that tend to promote health. Used in this sense the environment is facile princeps, but it should not be forgotten that drugs used for their general and local action are nearly always necessary as adjuvants to other directions and advice.

There are good reasons why repeated acute attacks of coryza, and repeated engorgement of the local lymphatic glandular structures lead to hypertrophic conditions. There are good reasons also why these repetitions occur at short intervals in some individuals and at long intervals in others. Things do not come by chance, and in these patients who are such an easy prey to local disease there must be some type of constitution either hereditary or acquired, or both, to account for their susceptibility.

Because the lessened general resistance which causes this susceptibility acts so often through the nervous system, and because the nervous affections of the nose are intrinsically of such interest when studied from the standpoint of this paper, one or two of them will be used as illustrations. We will speak of the group of reflex nasal diseases in which the irritation seems to be centripetal, and of hyperesthetic rhinitis, in which the irritation manifests itself centrifugally.

In regard to the so-called reflexes which are caused by pressure points within the nose, it has always seemed to me that the general system was more at fault than the nose. The nervous system of the patient had lost its nice adjustment, so that irritation at the periphery is manifested in some other region as reflex disturbance. It is recognized that the cause in the nose is only slight, but it is just sufficient to disturb the balance in a nervous system which has all but lost its poise. It will most often be found that individuals suffering from these reflexes are manifestly of a neurotic type, and although the existing malady is relieved by removing the peripheral cause, it will be found that the nervous instability still exists, and likely will evidence itself in other directions. In this class of cases it is important not to saw off a spur in the nose and assume that the patient is thereby cured, but by reconstructive treatment build up and regenerate. If this spur was causing asthma, or hay-fever, or tic douloureux, there is further work for the physician, even though the symptoms are relieved—for the general resistance of the patient must be improved or he will have headaches from some eye-strain, will have prolonged brachycardia after he has the grip—or some other ailment of like nature.

There is another type of nasal disease, the hyperesthetic, in which it is necessary to increase the tone of the nervous system before much improvement begins. The cases are somewhat similar in their manifestations to hay-fever, but do not seem to be influenced by season. In my experience the disease occurs most often in anemic individuals who have confining occupations and are suffering from some constant worry. These cases, like their near relative, hay-fever, undoubtedly evidence some positive interference with metabolism. Uric acid seems to be retained in most of them, but whether this is a cause or an effect, the lithemia improves as the patient gets better. Tonics, sunlight, less introspection will cure some of these cases, which are very baffling when treated by local medical and surgical means only.

The physician who treats diseases of the nose and throat should not be so narrow as to treat the local trouble by local remedies only. Æsop tells a fable of the members trying to boycott the body, but to their surprise they found that they suffered to as great a degree. The withholding of nourishment from the body caused not only emaciation of the body, but also caused other parts to be equal sharers in the calamity. It is a rule that works both ways. If the body had attempted to boycott the members, it would have had meted out to itself the same degree of suffering. I have seen many cases of chronic pharyngitis much benefited by the patient abstaining from alcohol or tobacco, and excessive taking of sweets will often so disturb metabolism as to cause a pharyngitis and tumescence of the turbinated bodies. Change of habits in this regard has led to relief of the local trouble. These are very familiar causes of disturbance here, but frequently other causes may be found, the removal of which will lead to just as satisfactory a result.

I wish to make a plea for a practical application of these facts. Not only should the patient coming to us with these local troubles be given instructions in hygiene, etc., in order to more surely throw off the local ailment, but one should make it a constant study to notice and consider his patient's mode of life and environment, and strive to be ready with advice that will forestall trouble.

In order to intelligently give the patient other than local treatment the specialist should always remember that he is physician first and specialist afterward. He should inquire carefully into the patient's family and personal history, the course of the present disease; and, except in cases which he knows can be permanently cured surgically, he should bring to his aid all the modern means of questioning the body. To do this methodically he should have minute notes of his cases. The card system is most convenient, and in private practice the financial account of the patient can be kept on the back of the case card appropriately ruled for that purpose. This will make it necessary to use and refer to the card at each visit and thus keep in touch with every phase of the local and general condition.

It sometimes requires close questioning of a patient to find just how he is transgressing the laws of health. The young lady eats "only a little candy now and then," but if you should happen to have her sweetheart as a patient during the same period, a little sympathetic questioning may bring out the fact that he is furnishing her 5-pound boxes of bonbons at more or less frequent intervals. Then your "moderate drinker" and your "moderate smoker" and your "slow and small eater" sometimes evidence an astonishing atrophy of their sense of perspective, and you may find upon going somewhat into statistical detail that they surely look at the things they consume and the faults which they have through the large end of a telescope. It is often a good deal of bother when we are busy to go into these minute and harassing details, but by so doing we put the practice of medicine and its legitimate branches upon a higher plane.

When the body at large requires treatment it is preferably administered by the laryngologist, especially when it can be done concurrently with the local treatment, but in some cases it is well to put the treatment into other hands. When so much depends upon relieving disturbances of metabolism and in keeping the whole body in a healthy condition, we surely are not doing the best for our patient if he is not given the benefit of modern appliances to secure these ends. While the specialist can not, and may not, limit himself to local work only, it is incumbent upon him to realize that some general treatments can be carried out better in other hands. He can not be expected to have the armamentaria needed for some cases; time does not permit him to become thoroughly conversant with all the kaleidoscopic changes in the whole field of medicine, and if he believes that some one else is better fitted to cure the general disturbance, the patient should be referred.

Prevention of chronicity, prevention of formation of hyperplasia, will save a train of complications which may mar the patient's future life. After many of the glands of the mucous membrane have been almost destroyed by chronic inflammation, after the function of an ear has been almost destroyed by chronic purulent otitis media, some relief can be given by modern treatment, but it is a make-shift after all. The glands can be stimulated to do twice the work they were intended to do and thus help out their shriveled companions, and the carious bone can be scooped out of the ear, but probably there was a time in the history of each of these cases when enlightened and conscientious oversight might have abolished the causes that led to these sequelæ. If we believe that heredity has something to do with these cases it is all the more important to prevent chronicity and recurrences; for then we are doing what we can to improve the type, and are building for the welfare of this patient's prospective descendents. Any good accomplished in any line of work is never in vain.

Ocular Disturbances from Thyroid Treatment.—The *Semaine Med.* mentions that two Belgian physicians have recently reported a few cases of optic neuritis or asthenopia as the only indication of intolerance of thyroid treatment. The ocular troubles subsided on suspension of the treatment.

SYSTEMIC FACTORS IN CATARRHAL DEAFNESS.*

SARGENT F. SNOW, M.D.
SYRACUSE, N. Y.

Chronic nonsuppurative inflammation of the middle ear by its very location is a most difficult disease to treat; and when we add to this the fact that it is rare for any of these patients to come to us until the disease is of several years' standing, we do not wonder that a doubtful prognosis has been the rule in the past, but if we are to call ourselves specialists, is it to our credit that we should sit calmly down and accept defeat, with our present facilities for reaching the deeper parts of the head?

Without frequent exacerbations an inflamed mucous membrane, even in the most advanced chronic form, is not beyond relief and practical cure. The number of our cases of catarrhal deafness where more than this simple inflammation obtains and the deeper labyrinthine structures are involved, is very small indeed; so what is our proposition but a simple one if gauged by some of the complex and serious problems that confront men in other specialties?

If the middle-ear trouble be in the earlier stages, what will do it more good than free and normal ventilation? Close the vestibule of one nostril and see how soon you will have a congested state of the membranes; open the vestibule and see how soon normal ventilation will restore health to the parts.

If the middle-ear affection has gone further and the ossicular chain is hampered by products of inflammation, what will assist their absorption quicker than that the parts be again bathed with a normal supply of air? What will limber up its stiffened joints better than the mild stimulation and passive motion produced by the well-known application of camphor and iodin vapor[1] puffed into the tympanic cavity? Stimulative treatment of this kind, by reason of its effect on products of inflammation and ossicular mobility, acts with practical certainty in benefiting the hearing. All this can be attained and maintained if the little Eustachian tube, not more than two inches long, be kept normally patent. The degree of improvement will be according to the completeness with which we have removed prime and contributing factors; this is no mean task, but, as a rule, possible, if we grasp the situation and apply ourselves. Hence I can not feel that we are justified in discouraging that multitude of cases under 60 years of age who still retain the ability to understand clearly spoken words, and who are quite ready to have treatment when medical minds will agree on its utility.

Nonsuppurative inflammations of the middle ear, regardless of form, depend upon similar conditions for their origin; the principles of treatment involved in their relief are the same. However, necessity does not demand a dissertation on varied abnormal conditions within the tympanic cavity, neither will I assume to cover in this paper all the factors that may act as causative elements, but rather will devote myself to those most likely to impede recovery of the hearing power.

In looking over recent progress it must be admitted that what ability we now possess to successfully cope with catarrhal deafness is in a great measure due to the advance in rhinology, for this work as a preliminary step to future efforts appears peremptorily demanded. The improved state that has followed correction of nasal abnormalities could not help but give happy results in the more simple cases, but it is likely that others have been balked as I have been by a goodly number who have failed to improve from those surgical methods as we hoped, and it is through a study of the causes of these failures that I chose the subject of this paper.

---

*Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The nasal, postnasal and tubal membranes are capable of, and susceptible to, engorgements from various causes; hence if we are dealing with a disease so obstinate as chronic catarrhal deafness, each possible source of a recurrence of those engorgements must be eliminated, or they will prevent a good result following the best nasal surgery, and the most careful after-course of ear treatments.

Among these systemic factors upon which it seems particular stress should be laid, are: 1, a sluggish skin reaction; 2, low vital forces; 3, torpid liver; and 4, a lack of proper exercise.

I have mentioned sluggish skin reaction first because nothing is more common in creating pernicious head colds to which, as a rule, our cases are subject; and when we attempt to correct this tendency to head colds, at least two interesting problems are before us: The solution of the first calls for a more prompt skin reaction, and I know of nothing better for this than cold baths and friction. The plunge, shower, douche, or even putting on water from the ordinary bowl by the hands, acts with much facility and benefit. In patients of low vitality this application of cold water may not be followed by the warm glow that indicates a good reaction unless preceded by some light exercise, or brisk rubbing, but in any and all events some course must be persisted in to get and keep the surface circulation up to a normal standard, the acquirement of which, though slow but sure, is best shown by its degree of reaction to cold.

In my own practice I find that patients, as a rule, take warm baths, and these only for cleanliness' sake; in fact we seem to be living in an era of carelessness as regards personal hygiene. The busy American jumps out of bed in the morning, washes his face and hands, hustles into his clothes, rushes down to breakfast and away to business, works until Saturday night, takes his weekly clean up, and so on year in, year out, giving himself less care than he does his horse.

Another problem in the avoidance of frequent colds is protection from exposure; which as experience ripens appears of less and less importance. While in a weakened individual, this is for a time unequivocally necessary and is always a point to be observed, still I believe with A. Chelmoski[3] that "the proper method of protecting against cold is not to wear an excessive amount of clothing, but to stimulate the skin to rapid reaction." This is a rational idea and appeals to us when we consider the importance of its glandular and circulatory functions. The only thing necessary is that we give this matter the thought and attention that we do other vital subjects. The skin reaction should be so prompt that it will be a shield rather than a menace to health.

The next systemic factor that our failures have shown to be a great hindrance, if we let it pass unnoticed, is a lowered vitality. Without a good general tone, the system is slow to throw off any disease, and particularly one so deep-seated as chronic catarrhal deafness.

A torpid liver or a lack of exercise, with attending digestive disorders, may also create and make obstinate an inflammation in the Eustachian tube, effectually blocking anything like a regular course of vapors to the middle ear; even gastric, uterine and renal troubles have their bad influence on the thickness of the membranes, but with many other constitutional causes, these latter require attention better, and beyond that which the aurist is expected or justified in giving. In other words, catarrhal deafness is often dependent upon so many possible causes or combinations of causes, that it calls into play not only the qualification of a nose, throat and ear specialist, but makes it necessary that he should have had the training of a general practitioner.

In cases of chronic type, correction of nasal and postnasal morbid states is but a small preliminary step. If patients be of low vitality, anemic and very sensitive, they must be built up. If they be full-blooded, their diet must be restricted, their exercise increased, and their hepatic function kept regulated until such sources of recurring attacks of tubal inflammation are obliterated. Of what use is it to treat inflammations that recur without we first remove their sources? We may benefit them for a few hours, but we lose the confidence of our patient, because we fail to get results on chronic states; he stops treatment and our efforts are discredited.

A limited number of persons become afflicted with deafness in early life, because of disease or environment, who at the time of our examinations are in good general health, with nothing in the way to prevent ear treatment except perhaps a tubal inflammation induced by some intranasal pressure. These patients are just so much nearer the period in which vapors can be satisfactorily applied to the middle ear.

A knowledge of hygienic care and how to increase bodily resistance to disease is a distinct obligation upon the otological specialist, but I hope I will not be construed as meaning that we should take it upon ourselves to correct complicated systemic disorders; though we should be able to relieve a congested liver, direct in matters of personal hygiene and insist upon their observance. The physician's duty is to correct causes and apply treatment—the patient's, to follow directions.

As mentioned earlier in this paper, catarrhal deafness is worthy our best efforts. As a disease *per se*, within reasonable limits it is comparatively a simple proposition if we eliminate all causes of recurring inflammations of the Eustachian tube. To be more explicit, I feel that its greatest problem is the removal of these causes; after-treatment consists simply in maintaining the improved condition and applying, daily if indicated, mild intratympanic ventilation, stimulation and massage. Persistent effort can be looked upon with favor; even the quite advanced sclerotic forms are not so formidable if pernicious influences are out of the way. Nature then takes hold with a ready hand and gives us, if not a cure, marked improvement.

Personal experience has taught that failure to improve the hearing power means either a fault in the patient or in the physician, not in the local ear condition. There must still remain some uncorrected extraneous cause that is keeping the Eustachian tube swollen. It is not the duration of the disease nor the degree of deafness that should govern our prognosis, but rather a good physical condition and the financial ability to have skilled attention.

The surgical aspect of cases as a preliminary step is important, but no more so than a functional equilibrium, for there is usually a stage following operative work in which but little if any effective treatment can be carried through to the middle ear, because of some attending systemic disorder, and those systemic disorders are determining factors in the majority of chronic cases.

DISCUSSION ON PAPERS OF DRS. STILLMAN AND SNOW.

Dr. C. M. Cobb, Lynn, Mass.—I would like to know whether Dr. Snow includes in his statement that these cases should be benefited in the presence of an adhesive catarrh?

Dr. Halsted, Brooklyn, N. Y.—I thoroughly agree with the Doctor in drawing attention to the systemic factors. Most of us spend too little time in the consideration of these facts. By paying attention to the systemic factors, we are often able to obtain results that otherwise would be impossible. But I disagree with the Doctor as to the frequent use of vapors and drug treatment of the middle ear, as he advocates. It has been my misfortune to see many cases become worse after a temporary improvement, simply because of too much local treatment. There comes a point when we can advance no further by local treatment in these cases. Because the patient is able to respond progressively better to a certain few frequently repeated tests is not necessarily evidence that the case is improving. A set of tests may give us a false impression of the progress of the case. If we use the various vowels, for instance, we find a certain improvement, but beyond this we can not go by the treatment with catheterization and the use of vapors. Often the catheterization and the vapors do harm. The catheterization may set up and keep up an inflammation in the Eustachian-tube, if used every day as the Doctor recommends, that simply makes the condition worse. I am not an advocate of the use of Politzer's douche alone.

Dr. J. O. Roe, Rochester, N. Y.—I am in thorough accord with the sentiments expressed by Dr. Snow. A great many cases of local engorgements about the upper air-passages are due to general systemic disturbances. In fact, the great majority of colds, to which people are so frequently subject, are due more to internal derangement than to external atmospheric influences. In the great majority of cases in persons who have taken a severe cold, in the head, for instance, by examining into the condition of the system we will find that it is induced or very much aggravated by a general sluggish or depressed condition of the system. During the past winter I myself had two severe colds in the head, starting in the nose. In both cases I could trace it directly to general disturbance, overwork and lack of exercise, and the condition we commonly term biliousness, which is often the foundation of colds. The colds in the head—which so often cause ear complication—are therefore due to two conditions; first, to ptomain poisoning, the poisoning of the blood from improper elimination of the skin, bowels, liver, etc., and second, to reflex disturbance, from the abdominal organs to the nose.

In regard to the treatment of the chronic ear affections, it is necessary, in the first place, to put the nasal passages in order. If we have an obstructed nose, a badly diseased condition of the nasal cavity, it is much more important to put the nose in order than to begin treatment of the ear, because if you could do but one you would benefit the patient more by putting the nose in order than by treating the ear for an indefinite length of time. After first paying attention to the nose, then, by proper treatment of the ear, we will often obtain most excellent results, in cases of chronic catarrhal deafness, that are considered incurable. There is a point in regard to the Eustachian catheter, to which reference has been made: The use of the catheter is exceedingly important for two reasons: 1, in medicating the ear through the catheter, and 2, in the mechanical effect of the catheter in overcoming a stenosis of the Eustachian-tube, which has resulted from interstitial thickening of the tissues around the tube, particularly at its lower end.

Question—I would like to ask Dr. Roe how he overcomes obstruction high in the tube?

Dr. Roe—In the majority of cases you can pass the catheter up through the membranous portion of the tube for quite a distance, and by having a proper catheter you can accomplish much in many cases. In some of these cases the use of galvanism produces most excellent results.

Dr. G. L. Richards, Fall River, Mass.—I can appreciate what has been said about elimination, as I have long been contending that the bowels should move at least three times a day, inasmuch as we eat three times a day. It has been observed, among animals, that they ordinarily empty the bowels much more often than we do. The removal of waste products of digestion has been so much influenced by the matter of convenience, that we have lost sight of the normal physiology of defecation in its relation to the ingestion of food. The question of ptomains as produced in our own bodies, from faulty elimination of waste products of digestion, has not received sufficient attention at our hands.

Dr. E. Pynchon, Chicago—Both papers are very commendable, inasmuch as they are conservative and call attention to systemic treatment, which is too often neglected. As regards the systemic factor in catarrhal deafness, one of the features to bear in mind is the disadvantage all of us derive from our modern system of living in overheated buildings that are too often poorly ventilated. We go in and out of these houses, stores, hotels, etc., several times a day, without any hesitation at the doorway, and without removing our overwraps. My own custom, during real cold weather, is, if possible, always to remove my overcoat when going in a warm place, and to stop for a time in the passage-way when coming out. Instead of wearing a heavy undershirt during very cold weather, I advise putting on two light-weight undervests, which give the warmth that is desired and do not overheat the body. Attention should be paid to the matter of food and exercise. There is no doubt that we eat too much, and that insufficient attention is paid to diet and excretion. One thing I would urge is the value of regular and frequent drinking of water. The same conditions which the Doctor has referred to as tending to produce catarrhal deafness also assist in the production of the so-called rheumatic diathesis. As regards treatment, while the Doctor has touched very little upon it, I can not refrain from calling attention to a new method of treatment recently introduced by Dr. Weaver, of Chicago, to which he has given the name "intratympanic massage." In the treatment recommended by Politzer there is massage at each inflation, but the inflations are not often enough repeated. The device recommended by Dr. Weaver consists of a small wind-mill, if you please, which is caused to revolve by a shunt of the air current while the bulk of the air passes through a hole in the shaft of the wind-mill, and is thus rapidly interrupted. I have been using this device with a Buttles' inhaler, while inflating by Politzer's method. Of course it will be understood that compressed air of proper pressure must be employed.

Dr. C. M. Cobb, Lynn, Mass.—We are a little inclined to the use of loose terms. Oliver Wendell Holmes said in one of his papers that our forefathers were very wealthy in expressions. He declared that he knew of nothing that sounds so well and means so little and is so satisfying to the patient "as congestion of the portal circulation." We have passed beyond that stage, and now we have lithemia and uric acid, which are terms referring to probably the same condition. The subject of an acute cold is interesting. The systemic condition has probably something to do with it, and the cold probably has something to do also with the systemic condition. When a man contracts a cold, whether he has lithemia or a local abstraction of heat from some part of his body, in a very large percentage of cases the cold will be found to commence in one of the chambers of the nose and pass then to another. Can anyone tell how any systemic condition or abstraction of heat from the body may cause the symptoms we call a cold? A man gets a cold in his head, and not much anywhere else in comparison with the amount in his head. These cases of catarrhal deafness are all prone to have colds, and this is largely due to nasal empyema. These patients are prone to have colds from over-indulgence and exposure, and the colds they get do not run the course of an ordinary coryza. Those cases deserve a great deal more attention; they should be sorted out and sifted out from other cases. When you eliminate all the cases that can be classed as influenza, or that depend upon an exanthem or pneumonia, the remainder of cases of acute rhinitis are probably of infectious origin. All those things have a direct influence on the ear. If that part of the naso-pharynx to which the Eustachian-tube leads is involved, and the lumen of the tube is partially or entirely closed the ears suffer, or the secretion from the nose or naso-pharynx may be carried to the middle ear by forcible blowing, or the ears may be infected by the extension of the inflammation by continuity of tissue. These patients would probably get well if it were not for more or less constant reinfection.

Dr. F. J. Quinlan, New York City—The question of prophylaxis of disease is one we should always consider. Many colds depend upon bodily fatigue and faulty assimilation. A man is exposed to some influence of cold and receives the germs of disease. The phagocytic action of the leucocytes is insufficient and the germs enter into the system rapidly. There is lymphatic stasis and there is no better or more accessible vestibule for the invasion of germs than the nose, which is constantly connected with the outside atmosphere. Therefore, if a man's system is lowered, the turbinates at once become congested and unable to empty themselves. The question of prophylaxis is largely in the individual. A celebrated pediatrician a few years ago tried to eliminate postnasal growths by dropping salt water through the nares, and someone told him that he would do much more good if he gave the child full length baths of salt water. Often the system is loaded down with non-assimilated products. The subjects of the papers are not properly emphasized. Water applied to the skin causes the greatest tonic effect in its vivifying influence. The rich can use it, but the poor are deprived of its use and hence we see the greatest number of these cases among the poor. We should let the people know of the good effects of water used both inside and out. The Doctor has spoken of clothing, but I think the question of beef is most important. These colds and conditions of congestion weaken the individual and start a train of ills that involves the nose and throat and every part of the mucous membrane.

Dr. S. F. Snow, Syracuse, N. Y.—I will answer Dr. Cobb's question as to whether I include the cases with fixation of the stapes. I do not. But how many do we have come to us that are or really get in that condition later on? Cases of fixation of the stapes do occur, but I doubt whether they occur often enough to warrant us in giving an unfavorable prognosis by the wholesale. One of the gentlemen has disagreed with me as to the advisability of such frequent local treatments. I wish to place myself before this Section, and the world if necessary, as willing to stand by the position I have taken. There are cases in which daily application might be harmful, for they are not yet in that improved physical state where local ear treatments can be effectively employed. But if we get other things out of the way, and secure a functional equilibrium so that the skin reaction is good, the liver normal, and if they are careful of their habits, we will find a time when they will tolerate the vapors and improve very markedly under their use. The more chronic the case the more often we have to treat them. I do not advocate treating these cases daily year after year, but very often I do for three consecutive months, the treatment to be repeated when unfavorable symptoms appear. As regards tests, my patients are rarely tested, except at the end of a course of treatments. I assure them first that we must clear out the nasal passage, and I accomplish that whether it takes one month or two or three. I do not encourage them to have the vapor used until they have had bad constitutional states corrected. I will not let them have treatment until they are ready for it. When the constitution is fit and they are willing to follow my directions, I am ready to treat them, and successfully. I am glad the paper has been so thoroughly discussed, and I can not convey the depth of my feeling regarding the importance of these cases. We must, as aurists, do something for them.

DIAGNOSIS AND PROGNOSIS OF EAR DISEASE.*

B. ALEX. RANDALL, M.A., M.D.,
PHILADELPHIA.

It is probable that most medical men, if asked as to the instrumental aids to the diagnosis of ear diseases, would think first and perhaps only of a speculum. Too many would try to excuse their failure to study a case by their lack of such an instrument; and yet many would undertake its treatment upon some fancied basis without knowing anything as to what was really before them or having the means and skill to treat it if they knew. The foundation of such foolhardiness is a total ignorance of the methods of aural diagnosis and skepticism as to the ability of any one to do more than guess in the matter. Yet it is axiomatic that diagnosis is essential to prognosis and both of these are requisites for any rational treatment. Even among men practiced in otological matters there is a woful failure to understand and employ diagnostic measures, with many consequent mistakes and much futile if not harmful work. Hence the need of discussing so trite and elementary a phase of our specialty as that which I have chosen.

To the patient, if not to the surgeon, prognosis is of vital importance. Upon the etiology and pathology of the various affections must depend the questions as to the urgency and the promise of treatment; and of these we can speak only from the standpoint of correct recognition of the nature, phase and complications presented in the case before us. So the life-history of disease, general and special, must be known to the specialist, as well as the details of the clinical picture met, and he must figuratively see through the ear if he is to make a good application of his special knowledge and skill.

Almost every diagnosis is based, here as elsewhere, upon the anatomy and physiology of the parts. Leaving aside the former subject, I will ask you to consider here only some of the physiological aspects which we ought to study as to the normal and diseased ear. We may premise that for the external ear sight and touch are principally available; for the middle ear with its air cavities, pneumatic measures; and for the internal ear, acoustic means.

It seems superfluous to insist upon the importance of unaided as well as aided sight and touch in our study, yet the numberless instances where their use has been neglected and gross blunders of diagnosis made because the practitioner refused to use his senses and yet undertook treatment on the strength of his imagination, compels reiteration of this trite matter. Many cases can be studied by the natural light falling past the examiner's head into the straightened ear-canal, to the recognition of furuncles, foreign bodies or the presence of a normal drumhead. Remember that Wilde did *most* of his work with nothing but a speculum, and often did not need that; yet many a modern aurist with a full armamentarium could learn much from Wilde's writings. Specula can be improvised of letter-paper or other material; any piece of mirror can be brought into use, especially with sunlight or other strong illumination, and a hair-pin or other bit of wire can be made into an admirable probe; but it is the eye and hand behind these or other instrumental aids which are the real means of diagnosis, and "special" training is by no means essential if a true physician, with gentle hand

---

* Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

and observing eye, undertakes these studies. Even in palpation there are many ways of failing to learn. A swollen mastoid may seem tender and fluctuating to a careless hand, and a trephining be advised when carefully placed index fingers would prove the swelling a mere edema and the pain not due to deep bone-lesion, but to the motion imparted to an inflamed canal. One may recognize blindfolded the indurated rigidity of an eczematous canal in which a keen eye may discern no surface signs of the affection, and by proper prognosis avoid imminent distress for the patient and humiliation of himself. Touch must aid sight in many tympanic conditions before we can know what are the real features of the picture presented, by sweeping away the seeming landmarks and proving them to be but pus, epithelium or other foreign matters lying in front of the real structures.

Yet even when the diagnosis thus made is clear and positive it may be only superficial and partial. The manifest lesion may conceal something beneath which is far more important. A trivial furuncle of the canal may mask a serious tympanic inflammation and we must often remain in doubt as to the conditions beyond. Here the pneumatic methods of tympanic study may aid us greatly, but still oftener the acoustic measures which investigate the percipient apparatus and its adnexa.

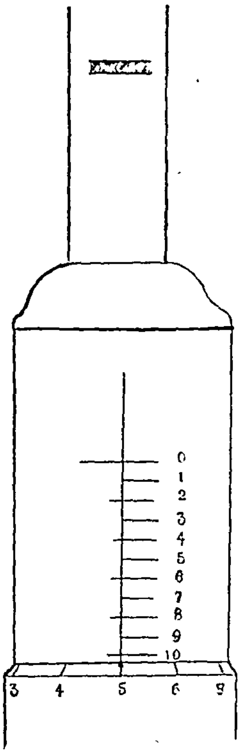
Of inflation measures and pneumatic massage much might here be said, for more can be done with these and more mistakes avoided than is at all sufficiently realized. I feel need of calling attention to Löwenberg's simple test of inflating chloroform vapor, which by feeling cold to a sclerotic ear, instead of hot as to all others, may give us early a very important prognostic sign. Yet the acoustic tests are still less fairly understood and practiced, and it is upon these I would prefer to lay my main stress.

Almost every expert is on record as to the small value of the watch as a test, and Politzer's acoumeter, although well conceived, has not much better met the requirements. Still less have some of the haphazard substitutes which have been put forward for railway and school tests any claim to be accepted as having standard or comparable value.

The voice-tests in faint and loud whisper, spoken with the "reserve air" which can be forced out after ordinary tidal respiration and calling for repetition by the patient of the well-chosen test-words, are far more precise as well as practical. But all these are quantitative rather than qualitative measurements of loss, not helps to recovery. We must have a "tone series," in form permitting comparison of conduction by bone and by air, before we can learn some of the most elementary and fundamental data.

It may be too much to expect that the general practitioner should in preparation for his few ear-cases equip himself with a series of tuning-forks, and even the specialist must draw the line at some of the numberless implements urged by enthusiast or instrument-maker upon his attention, yet lack of a well-selected complement must seriously impede if it does not vitiate his diagnostic work.

When we hear a man say that he puts little confidence in the results of the tuning-fork, we may be fairly sure that he has but a single fork and makes poor use of that. One fork is competent to give us but a part of the information needed in many cases, although it can be very valuable within its field, and I would place a fork of some 200 double vibrations per second as the first choice in the series (A-213). It should be of a good size, so as to have 80 to 100 seconds' duration of sounding after a moderate blow, such as that of falling its own height upon the knee or a rubber block, but some of those offered are far too heavy and, with their clamps, needlessly expensive. Some means of suppressing the over-tones is requisite, but a bit of rubber-tubing drawn over the ends is at times better than the clamps. A fork of some 500 vibrations (c-512) is more generally recommended and can be purchased for 25 cents, in small size, at most music stores. Another of two or three octaves higher pitch, 2-4000, has occasional usefulness, but one two octaves lower than our first choice is much more valuable (A-53). The octave below this is of doubtful audibility, while this tone ought to be heard by any normal ear, and it is so early lost in cases of obstructive lesion that it forms almost a premonitory indication of commencing catarrhal deafness. The higher tones already mentioned better serve to test the percipient apparatus, but are surpassed in this by the Galton whistle or the König rods with their far higher range. A cheap and handy substitute, of real though of limited value, is furnished by the little bent-wire "serpentine screwdriver" sold in most of the bicycle stores, all of those tested having had tone of fair purity of about 35,000 double vibrations per second.



THE GALTON WHISTLE.

APPROXIMATE PITCH IN DOUBLE VIBRATIONS PER SECOND.

5=52,000
10=40,000
12=35,000
18=30,000
21=25,000
24=20,000
28=15,000
35=12,000
48=10,000
60= 7,000
70= 6,000
84= 5,000
105= 4,000

The Galton whistle, however, is of wider value as originally made, and may be more precise yet in König's and Edelmann's improved forms. I must warn, however, against most of those offered for sale, since they are generally travesties upon Galton's instrument, and of no more value than a boy's willow whistle. Even some coming from Meyer & Meltzer, in London, have not conformed to the original apparatus, and I know of but one maker in Philadelphia and perhaps one in Boston from whom standard whistles have been obtained. The square-cut opening, the proper caliber of the tube, correct pitch of the screw, and accurate zero-point are one or all absent in many of the alleged Galton whistles offered; yet all of these characteristics must be demanded if any standard is to be maintained. Some of the published results from tests are to me inexplicable, if genuine Galton whistles were employed, so utterly discrepant are they with my findings. A tube length of 10 mm. ought to give a note of about 21,000 double vibrations per second, and one of 1 mm., corresponding to one full turn of my instrument, a tone of 42,000. A higher note than this is audible to most of my patients as well as to myself, and I would set the normal limit for young ears above 50,000, as I have no difficulty in hearing Appun's 49,000 fork or the Galton whistle at less than one turn.

Qualitatively, then, we ought to determine for all our cases whether they hear tones as low as 50 and as high as 40,000, and between these moderate limits make fuller test with two or more forks, while in those giving evidence of nerve lesion a wide range should be tested by the whole scale of the Galton (4000 to 40,000) and a number of lower tones.

In addition to these studies of the hearing by air-conduction, we need direct and comparative tests of the bone-conduction, remembering that there is a senile loss of the conducting power of the cranial bones aside wholly from faulty perceptions, and that the palpable vibrations which are as notable on the patella as on the mastoid, must not be confounded with the audible. Weber's test of the lateralization of the vibration to one ear from the middle line of the head had better be preceded by Rinne's test, since it is hard for many patients to believe their own senses when the tone seems louder in the worse ear, which they have perhaps long regarded as totally deaf. While the Schwabach method of timing the duration of the tone by air and by bone is eminently valuable, the simplification made by Roosa and Emerson is even more practical, consuming less time and securing better responses from most patients. If the fork, not too strongly vibrating, is held close before the ear and then its handle rested upon the mastoid, with the question, "Is it better front or back—back or front?" suiting the action to the word, few have difficulty in answering correctly; and as the loudness and the duration are comparable, we learn whether the normal preponderance of air-conduction exists or not, and can easily move the fork to our own ears for quantitative comparison. As the ordinary A fork (213) should be heard on moderate stroke only about 45 seconds by bone, as against 100 by air, the preponderance, as often found in tympanic cases, marks a decided impediment to the due penetration of the aural sound-waves through the affected conducting apparatus. It is easily demonstrated that this same obstacle shuts in, so that the fork vibrating upon the head is heard louder and longer than normal—perhaps for 50 or 55 seconds. This is best shown by the simple test of Gardiner Brown, which consists in holding the handle of the slightly vibrating fork upon the bridge of the nose and noting how much greater or less time the patient can hear it than the examiner's fingers can feel the vibrations. Cessation should seem simultaneous to each, and in spite of personal equations one second of discrepancy can generally be noted by this means, and secondary involvement of the percipient apparatus thus detected. The Weber test then used, by resting the vibrating tuning-fork, not on one, but a series of points in the middle line of the head, will generally obtain a correct answer and be lateralized to the worse ear in obstructive, to the better ear in perceptive, lesions. Results which are doubtful with a fork of 200 or of 500 vibrations per second, will often be unmistakable if those of higher or lower tones are employed, and due care be exercised to set aside any preconceptions of the patient and to elicit answers not as to what they *think* but as to what they *hear*.

Far too little employed is the valuable test of Politzer as to the permeability of the Eustachian tubes in the act of swallowing, for the tuning-fork vibrating before the nostrils should be heard much louder at the moment that the tube opens in deglutition. This tells of its physiological action as contrasted with its more passive distensibility on inflation, gives clear contrast as to the two ears and often tells more as to the stage and prognosis than any other test at our command. Bing's test also proves at times valuable, in that the tuning-fork vibrating on the mastoid can be made again audible after it had ceased to be heard, by stopping the canal with a finger; and as this secondary perception should have a measurable length in cases of nerve-lesion we may recognize the coexistence of slight conduction impediment by its subnormal duration.

While the complaint of the patient and some of the details of his history should always form a part of our record, more valuable facts of the history will often be gained by our objective study and due correction made in his statements.

The objective findings should then be noted as to hearing for conversational or whispered speech; for the 50, the 200, the 500 and the 2000 v. s. tuning-forks and the Galton whistle by air, and for the 200 fork by bone-conduction from the mastoid and from the nose; for the Politzer's test of Eustachian patulency and for the lateralization from the middle line. Add the findings of the otoscopic examination, of anterior and posterior rhinoscopy and the response to inflation and pneumatic massage. These, added to the name, age and occupation, form a record concise, quickly obtained and pregnant with meaning for correct diagnosis and prognosis.

DISCUSSION.

Dr. J. Holinger, Chicago—The Doctor showed us his series of tuning screw-drivers. They are undoubtedly irregular in their intervals and the time they keep on ringing is too short. To overcome these two cardinal points was the effort of Bezold and Edelmann for over ten years. Why did he not use those beautiful sets of tuning-forks of Bezold-Edelmann? They contain from sixteen vibrations up to the highest, without interruption. The number of vibrations is given on each tuning-fork. They are mathematically correct. It would be impossible to compare the Doctor's records of cases with the sounding screw-drivers with the records obtained by anyone else. Then as to the square opening in the Galton whistle, it has long been proven irrational and the oval opening has been found much more sharp in its results. Edelmann had to provide for an opening that could be made smaller or larger. If the opening is unchangeable the oval opening is preferable, and its results are *not* worse, as I can prove with Koenig-Schwendt's dust-figures.

Dr. Edwin Pynchon, Chicago—The paper has been very instructive. Two months ago I heard a similar one read before the Western Otolaryngologic Society, at St. Louis, and I then called attention to a little procedure which has been of assistance to me when the patient is in doubt about the Weber test. Supposing the left ear is affected and the patient claims to hear the test best with the right ear. I then stop up first the right ear and then the left, repeating the test. Afterwards, without stopping either ear, I again place the tuning-fork upon the top of the head, when the patient correctly tells in which ear the test is best heard.

Dr. E. Amberg, Detroit, Mich.—We know that Politzer's instruments are in general use, but I have heard on good authority that they *do not compare* accurately one with another. I thought I could overcome this difficulty by having an apparatus constructed on a different principle. There came to my mind the apparatus which is used for the measurement of the depth of sleep in the psychophysical laboratory. I had such an apparatus constructed in Berlin, and I think that these instruments may compare more favorably one with another. However, I do not know whether those fine points are of such great value in our daily work. At any rate, we should make it a matter of principle to try to be as exact and correct as we can. Therefore, I would take exception, at least for the use of the specialist, to this little instrument which is intended to replace a tuning-fork, shown to-day. Professor Loeb, in a conversation, if my memory serves me right, told me that experiments had been carried out under his direction. years ago, with the aid of an instrument similar to the one I have mentioned. If I am not mistaken, the experiments to which Professor Loeb referred were intended to establish facts as to the acuteness of hearing under various conditions. It is important, I think, to consider conditions under which hearing tests are made. I remember that one time when I had overworked myself I thought I heard the clock at 11 p.m. strike twenty-seven times. It was, if I remember correctly, after I was fatigued through study. The time of the day and the other conditions of the patient, I think, should be taken into consideration when a hearing test is made.

Dr. B. A. Randall, Philadelphia—I have the Edelmann tuning-forks and they are very nice, very useful and pretty, and as specious as any that are made, for, like the Politzer acoumeter, they are apt to differ in tone and loudness and other essentials, so that in a dozen you could hardly find two that do not differ. I have not tried to split hairs, but only to get at the diagnostic points that are of value in treatment. So I have not tried to lay down just what should be the precise limits as to time and distance that the fork should be heard. As to the Galton whistle, I have brought that forward because the prime essential lies in the fact that we are dealing with a closed pipe and must have a definite length and that length can not be defined if the opening is not rectilinear. Edelmann's new whistle may be as specious in many respects as the set of rods I have, which he said he had made for Koenig's rods; but they were inaccurate, arbitrarily numbered and what they stood for he could not tell. I have much respect for the good work done on the other side of the water, but the very bad work I have seen emanating from Edelmann and other men has made me favor the work done on this side of the Atlantic.

EFFECT OF ALCOHOL ON THE NERVOUS SYSTEM, THE MIND AND HEREDITY.*

ALBERT E. STERNE, A.M., M.D.

Professor of Nervous and Mental Diseases, College of Physicians and Surgeons; Neurologist to the City Hospital, Etc.

INDIANAPOLIS, IND.

Alcohol has a twofold effect on the nervous system, a direct or primary, and an indirect or secondary. Either of these may act physiologically, i. e., functionally, or pathologically, i. e., structurally. Either may and does unfold its force upon every part of the nervous system, brain, cord, and peripheral nerves; in fact on every organ and tissue of the body, notably upon the blood-vessels, particularly of the brain, the kidneys and the liver. The subject is too large to render justice to it within the limits of a paper like this, and I shall, therefore, be forced to confine my remarks to a narrow domain.

Upon the nerve tissues alcohol has an acute influence. This can best be studied by experiments on animals, and by the effects shown in fatal poisoning with large amounts of alcohol in persons unused to its influence. Of the ordinary state of acute intoxication, I need not speak. That picture is familiar to all of us.

In a very able paper, Dehio,[1] some years ago, demonstrated changes in the ganglion cells of the cerebellum produced by acute alcohol poisoning. A year later, Stewart[2] confirmed and extended the observations of Dehio, which consisted in the diminution of the chromophile granules of the nerve cells of the cerebral cortex, the Purkinje cells of the cerebellum, and the large multipolar cells of the spinal gray matter. The importance of these changes is vastly increased in the light of the theory that the ganglionic cells possess certain powers of mobility of an ameboid nature, which permits them to extend and to retract their cell-prolongation to a slight degree, producing normally a contiguity of structure *without* continuity. I believe in this theory, for it is the only one which explains to me the phenomena of life, both in rest and in activity. Into that, however, I can not enter further at present.

I have in mind a unique, unpublished case which may bear a close relation to the observations of Dehio and Stewart. It is that of a young man who, about one year ago, was referred to me. The patient presented a most curious complex of symptoms, which I have nowhere found described, and which I herewith take the opportunity to record.

F. W., white, a farmer, aged 19 years, had up to about seven months previous to my seeing him been quite well, and constantly engaged at work on his father's farm. During a period of perhaps a year before any symptoms had become manifest he had been drinking somewhat, but had never indulged to intoxication. Gradually a general lack of nutrition set in, he began to lose weight and strength, and almost imperceptibly, at first, peculiar spasmodic seizures supervened. These attacks were wholly motor in character, occurring, as the malady developed, more and more frequently until, when he came to my sanatorium, they were almost constant, recurring at the actual rate of about once every two minutes, day and night. During the entire period of the affection the appetite was excellent, no symptoms were shown by any of the internal organs, no sensory changes were manifest, nor were the secretions altered, save that the urine was somewhat scant and perspiration slight. In fact, all symptoms related to the motor nerve sphere, though at no time was there the slightest degree of paralysis noted. The seizures were characterized as follows:

Every few moments the muscles became tense and rigid, apparently all over the body—trunk and limbs—face neck, eyes, tongue, larynx, esophagus, etc. During the attack, he could usually make voluntary movements, but he could walk, talk, breathe and swallow with difficulty. The facial muscles and masticatory muscles became "set" and the neck stiff. There never was any inclination to opisthotonus, nor the slightest loss of consciousness. No vasomotor signs were present, the cutaneous and pupillary reflexes were normal, but the deep tendon reflexes were somewhat increased. He suffered no pain whatever, but some muscular soreness existed, doubtless due to the muscular contractions.

At the first examination, I declined to give a positive opinion of his case, but expressed the conviction that the malady would not remain stationary, that it would either prove rapidly fatal, or he would recover under proper treatment within a few weeks, advising careful observation and treatment at the sanatorium. At that time I felt sure I could bar out an hysterical affection of which no symptom was shown. My advice was followed, and the patient remained under my immediate care for nine weeks. During this period he steadily improved under static electricity, massage and the use of tincture of gelsemium, ten drops thrice daily, until complete recovery occurred. The seizures gradually decreased in frequency and intensity until they ceased altogether. I would perhaps not have mentioned this case in this connection except for two facts. 1. The only etiologic factor to be elicited was that he had used alcoholic drinks before the affection obtained. 2. On three separate occasions, when he had almost recovered, friends came to visit him and he indulged in a glass of wine with the result that, each time, the attacks recurred with their former force and frequency, proving to me conclusively that there existed the most direct relation between the seizures and the use of alcohol which produced this peculiar multiple paramyotonic condition. I have never heard of a similar case.

---

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Heinrich Dehio: Experimentelle Untersuchungen über die Veränderungen der Ganglienzellen bei der acuten Alkoholvergiftung; Centralbl. f. Nervenheilkunde und Psychiatrie, 1895, N. F. 6-113.

[2] Colin C. Stewart: Influence of Acute Alcohol Poisoning on Nerve Cells: Jour. of Experimental Medicine, vol. i, 1896, p. 623.

Undoubtedly, many other examples of the toxic character of alcohol and its influence on the nervous system could be cited. I need merely make mention of the analogous states known as delirium tremens, due to the excessive use of spirits containing large amounts of fusel oil; of the ordinary phenomena of acute intoxications in which the loss of inhibitory power in all spheres is of such common occurrence that it is usual to accept the opinion of the stimulating effect of alcohol on mental activity. This opinion I regard as decidedly erroneous. There is a vast difference between increased functional brain power and diminished inhibitory power, but momentarily the apparent effect may be similar.

When we come to speak of the more chronic condition called "alcoholism" we meet with a very different entity. Here can best be seen the effect of the poison on the nervous system, owing to the fact that widespread changes have taken place in the central nervous organs.

Of these changes those of the vascular system of the brain are by far the most common. It would appear, therefore, that the effect on the nerve tissue itself is purely secondary, due, in other words, largely to malnutrition of the nerve elements. The alterations in the structure of the artery walls are widespread and frequently reach a high degree, even to obliteration of the lumen of the blood-vessel and consequent softening of the brain tissue. Even a slight degree of textural change in the arterial structure is apt to be followed by an array of symptoms, made up chiefly of those in the motor field, such as tremors, weakness, etc., and those appertaining to the highest functions of judgment, memory and other intellectual faculties.

Of the many pathologic conditions supervening on the use and abuse of alcohol through a long period of time, it is surely unnecessary to speak at length. I need merely mention the frequent inflammatory processes of the peripheral nerves termed "alcohol neuritis," and reiterate the importance of the structural alterations of the blood-vessel walls with increased arterial tension, loss of vascular elasticity, consequent infiltration with calcium salts producing arteriosclerosis and endarteritis, which makes the danger of apoplexy lie close at hand. It must be recollected that *no healthy blood-vessel ever bursts save* and *alone* as *the result* of *traumatism. Whenever* and *wherever an artery breaks,* except it be due to injury, *the vessel must be diseased.* Moreover, no single factor contributes so largely to disease of the blood-vessels as much as the chronic use of alcohol poison. I have already alluded to the psychic changes of such individuals, to the loss of judgment, memory, and the other intellectual faculties, inducing changes in the products of the brain—the mind and morals. It is this which brings this question into close relation to civic life, which makes it the greatest civic psychosis.

Before speaking of the influence of alcohol on the mind, let me preface by saying that there exists in almost every case of insanity a well-marked predisposition of the individual to the development of mental disease. It would follow, therefore, that few persons of actually sound condition, anatomically and physiologically, ever fall victims to these affections. Again, it naturally follows that the weaker the inducing cause, the more pronounced should be the tendency toward deterioration. Conversely, it may be said, the more marked the atavistic tendency is, the less will be required to assist in the transition from the realms of sanity to those of mental disease.

Of the minor, practically merely contributing factors may be mentioned overwork, overstudy, emotional effects of an occasional character, the strain of acute diseases, and religious influences. You will understand that I nowise underrate the dignity of these elements, whose import is disproportionately increased if they become coincident with the physiologic periods of life.

Among civilized peoples, it has for generations been rightly deemed necessary to segregate the mental sewage of humanity. It should, therefore, be recognized as equally incumbent to thoroughly inquire into the chiefest causes through whose malignant influence these channels are kept full to overflowing. By such investigation, and by the lesson it teaches, can we hope to stem the steadily—if slowly—increasing tide of human forces whose awful effect is best seen in our insane asylums and in their close relations, the penitentiaries.

I have long held to the view that every disease has a basis to start on, and that no so-called "drug habit" forms an exception to this rule. Chronic alcoholism and its sister maladies, like morphinism, develop on a pronouncedly neurotic basis, and it seems to me the lack of success in the treatment of these affections is largely due to the fact that this neurotic element has been neglected. Allow that foundation to remain and the malady recurs. Alcoholism and similar vices belong to the realm of borderland, that great expanse abutting on insanity, and it takes but some slight contributing cause to pass over into the latter.

It has already been intimated that every individual case shows more or less predisposition to deviation from normal mental and moral standards. While the fact is true, the import of this is almost lost in comparison with noxious social and civil influences which are unfolding widespread effects. I fully realize the importance of this assertion, when I say that society and its social laws, civil life and its license are almost wholly responsible for the overcrowded condition of the insane hospitals and prisons, homes of the mental and moral degenerates. A charge so serious should be well founded. I shall seek to justify it.

The evolution of the human race is but the evolution of the individuals composing it. To evolve a perfect race, perfect individuals must be evolved. No nation passes into decadence and degeneracy save through the decay and degeneration of its components. Such truths must be quite apparent. Let us ask ourselves, then, what elements are mainly at work in the production of individual mental and moral deterioration, for the time being leaving entirely unheeded the many minor incidental factors.

The main causes I have already stigmatized as social and civic evils. To these I count habits of all kinds, yet most of all the use of alcoholic drinks; to these I count lack of hygienic principles which permits the gross spreading of diseases; to these I count, most important of all, the total disregard shown throughout the world to the bringing into it of human beings unfit to live. Daily, thousands of poor bundles of humanity are born into life with infinitely less concern for their future welfare and perfection than is exercised in the breeding of our most common cattle.

Alcoholism is a disease, an enormously frequent one, whose ravages are tenfold worse than any other known to me, for unlike them its effects are not arrested by death. It is neither my purpose nor my desire to inveigh against the use of alcohol, but to bring to your notice the malignant effect of its abuse. You must recognize alcoholism in its chronic form as a disease. It is attended by a huge array of symptoms. Suffice it to say that chief among them is the material change in the structure of the blood-vessels, notably in the brain and kidneys, and that secondarily, and sometimes primarily, minute alterations in the intrinsic nature of the brain cells occur, which ultimately bring about total wreckage, physical, mental and moral. Unfortunately, there is nearly always a marked tendency of neurotic character present which permits the development of any vicious habit, and this tendency is decidedly transmissible and augments by transmission. The appalling truth of the latter statement is amply verified by experience with the innocent offspring of alcoholists. Go into our homes for feeble-minded, enter the reformatories for boys and girls. There, surely, personal histories repeat themselves. There, surely, the traits and tendencies of ancestry can best be studied and the secrets of hereditary burdening and bondage be learned.

The influence of heredity has never been questioned in the domain of psychology, normal and perverted. Yet it must be plain that to speak of heredity means simply to accentuate certain phases of transmission, good and bad. With a few specific exceptions, disease is never handed down to progeny from the ascendants. As we inherit peculiar quantitative traits, so we assume peculiar qualitative elements from those to whom we owe existence. As children inherit looks and features so, too, they show certain characteristics of disposition, which, when they become predominant, form a predisposition or tendency in the one or other direction. That this predisposition can be checked or fostered is a well-known fact to every student of evolution; it is even known to every breeder of livestock who studiously seeks to eliminate the bad and foster only the good qualities of sire and dam. Shall we, human beings, gifted beyond all other forms of animal life, be less faithful in the pursuit of developing ideal offspring? Yet, as a rule, that is exactly what is being done. Mental cripples crowd our asylums for the insane, moral ones constitute our criminal classes, and these crowd our prisons and reformatories. The two are closely related and both are manifestly the results of existing social and civil principles. I most earnestly believe that the factors I have spoken of are the main causes —aided, it is true, by many of the lesser degree—which make it necessary to maintain the many institutions for the care of the insane and the imprisonment of the criminal, all for the sake of protection to the welfare of the general public.

In conclusion, let me emphasize by repetition the import of the foregoing. As I frequently tell my students, "it is not the man who occasionally becomes intoxicated who gets into trouble, but the man who drinks much and never gets drunk, or he who is nearly always drunk, that becomes a candidate for disease." His are the blood-vessels that early grow less elastic and more brittle, his are the chances for apoplexy and consequent infirmity, his are the weakened will-power and moral force, his are the nerve tissues that show slight vitality. His, again, are the offspring of stunted intellectual mold, who lack the ennobling qualities of men and women, but show to a marked degree the signs of mental and moral and physical degeneracy, which make them easy victims of epilepsy, imbecility and idiocy on the one hand, and, on the other, gives them the inherited and acquired right to a berth in the insane hospitals, the jails and the penitentiaries.

If but the true import of the alcohol question were understood and a proper conception of the effect of alcohol on the physical and mental qualities were gained, I believe few generations would pass before we would find in place of our institutions for restraint and punishment, hospitals for the care and cure of a class of patients more ill often than those whom we generally regard as sick or diseased.

DISCUSSION.

Dr. A. J. Pressey, Cleveland, Ohio.—The Doctor has covered the ground very completely, and I would say "amen" to what he has said.

Dr. G. W. Drake, Hollins, Va.—I would like to ask the speaker to tell us the difference between the effects of pure alcohol diluted, and the various preparations of alcohol in the form of whisky, brandy, etc. I have never had any experience, but I always had a desire to know whether it is more injurious or dangerous to use pure alcohol diluted or whisky or brandy. I notice he spoke of fusel-oil. Alcohol has the advantage of not containing it. I am only entering a protest against the idea that the mind is capable of becoming insane, drunk, intoxicated or affected by any material disease. The brain may become diseased, but the mind is not subject to any effect from material objects.

Dr. Albert E. Sterne, Indianapolis, Ind.—I only wish to apologize to the Section for cutting up my paper the way I did. I have taken the standpoint that nobody ever forms a habit except from a neurotic predisposition. It always has a basis to develop on, like any other disease, and the use of morphin and alcohol must be looked upon in its chronic form as a disease. Whether mind or matter is diseased is immaterial, it does not make much difference, and so far as the mind being capable of disease, that is something which I do not feel able to speak upon. My conception of mind differs from that of my colleague.

As regards the use of small doses of alcohol and alcohol in any form, I may simply reply that a poison is a poison no matter how it is taken. Mercury is mercury, no matter in what form we give it. The more refined the spirits, the less side issue will prevail, but the intrinsic effects of alcohol are never altered. There is a vast difference in the use of alcohol, say in the form of whisky, and beer as used in Germany. In the use of beer there is a mechanical effect observed. The large quantity of fluid dilates the blood vessels, and this insult to them renders them less elastic and, in addition to that, there is a large nutritive element which, if it is taken up as nutrition, means more work for the heart, because the new tissue must be nourished. You are overburdening the organ and, therefore, the effect on the ventricle is weakening; this is seen in beer drinkers, where it is not seen in alcohol drinkers or morphin habitues.

The question is entirely too large for me to cover in such a manner as this. I took it for granted that the alterations were all well known to members of this section. I have spoken to several neurologists about the peculiar case reported, and they have not been able to throw any light on it, or add to my conception of it.

Accidental Vaccination.—Apropos of a case of accidental vaccination reported in The Journal of March 2 (p. 584), another reported in *The Lancet* of February 23 is of interest. It was that of a man of 45, who, on Sept. 14, 1900, received a slight scratch on the outer angle of the right eye. A week previously his child had been vaccinated, and, in caring for the child at night, during the mother's illness, the scratch became inoculated from the child's arm. The man's eye became very painful and irritable, with symptoms of septic poisoning.

A CASE OF COMBINED GASTRIC AND AURAL VERTIGO, WITH A DISCUSSION OF THE PATHOLOGY OF SUCH CASES.[*]

G. W. McCASKEY, A.M., M.D.

Professor of Clinical Medicine and Nervous Diseases, Fort Wayne College of Medicine; President of the Indiana State Medical Society.

FORT WAYNE, IND.

The pathology of the symptom known as vertigo is obscure in a great many cases. It seems quite clear that in some, and that a rather large number, it is the direct or indirect result of general causes acting on the nervous or vascular mechanism. As a temporary phenomenon it is often present in states of general debility, from whatever causes arising, especially on assuming, or suddenly relaxing from, constrained positions, or making sudden movements of the head. To a variable extent it forms a feature of the various acute and chronic intoxications both heterogenetic and autogenetic. It is a very frequent symptom of organic brain disease. Mendel says that every focus of organic brain disease will necessarily influence the cerebral circulation, and may consequently be associated with vertigo. This is especially true where the lesion is situated in a posterior fossa.

The present tendency on the part of some writers, Gowers among them, is to assume, where it can not be demonstrated, the existence of labyrinthine disease in practically all cases of so-called definite vertigo. While the relation of the labyrinth to the sense of equilibration, as well as to the equilibration itself, is clearly proven, yet it seems to me that the clinical evidence in favor of morbid conditions elsewhere being the efficient cause of definite vertigo is entirely conclusive. For instance, Osler has recently reported a case of vertigo of eighteen months standing entirely cured by properly-adjusted glasses. That such cases are necessarily due to co-existing latent labyrinthine disease is an assumption which lacks adequate support; and rests mainly on the clinical fact that an ever-increasing number of cases of vertigo, formerly attributed to various causes, have been shown to be connected with labyrinthine disease, which is the admitted cause of a very large majority of all cases of paroxysmal vertigo; and in part to the assignment of a too exclusive rôle to the labyrinth in the function of equilibration. It seems more probable that the superior olivary body, with which both the third and eighth nerves are intimately associated, and which, it appears probable, plays an important part in equilibration, has much to do with both labyrinthine and ocular vertigo. Ewald's experiments in which dogs slowly recovered the power of equilibration, after the extirpation of the labyrinth on both sides, seems to indicate that the essential mechanism resides in a ganglionic center. But in any event, whether the hypothetical labyrinthine disease is always present or not, it is obviously true that without the ocular strain or other condition so often occupying the relation of an obvious immediate cause, the vertigo would not exist. With reference to vertigo from oculomotor disturbances, Mendel has called attention to what he believes to be an important anatomic fact in relation to vertigo of ocular origin. He finds that the nuclei which preside over the movements of the ocular muscles are supplied by fine terminal branches of the posterior cerebral arteries, which do not anastomose, and that the vascular supply of these nuclei is therefore easily interfered with. It would seem as though involvement of these vessels might possibly be one reason why vertigo is so constant and early a symptom of arteriosclerosis—especially in those cases of comparatively rapid type, and especially if, as Mendel believes, true vertigo is always associated with disturbances of the eye muscles.

The nature of gastric vertigo, to which attention was long ago called by Trousseau, has given rise to considerable controversy. No one denies the frequent clinical combination of gastric disease and vertigo, and in apparently close relationship. Gowers, however, while admitting that paroxysms of severe vertigo are caused by gastric disturbances, doubts its purely gastric origin.

It is probably true that in some cases of undoubted labyrinthine vertigo the paroxysms are precipitated by gastric disturbances, and that many of the cases formerly regarded as gastric are really aural. But I do not at all believe that the assumption of labyrinthine disease in every case of apparently gastric vertigo is sustained by the facts.

In the first place it appears to me that a sharper distinction should be drawn between the balancing power and the balancing sense, and that it is the former rather than the latter with which the labyrinth is essentially concerned, although both functionally and anatomically the two must be closely correlated. Whether the cortical center of this balancing sense is in the temporal lobe or elsewhere, it is perfectly natural that it should or might be disturbed by any perturbation of the cerebral circulation—an inference which is fully borne out by clinical and pathologic evidence. That such disturbances do arise from oculomotor mechanism appears perfectly plain, and that they may arise from disturbances of more distant organs through more circuitous nervous channels is not in itself improbable. With reference to the relation of the stomach to vertigo it has been suggested that the latter may be caused by a morbid stimulation of the terminal filaments of the vagus in the gastric mucosa, reflexly exciting the motor nerves of the labyrinth and thus affecting the pressure of the endolymph in the semicircular canals. It is worth while bearing in mind that there appears to be a close relationship between the vomiting center and the sensori-motor mechanism concerned in equilibration. In most forms of severe vertigo nausea and vomiting sooner or later supervene. Whether we are able, therefore, to demonstrate the modus operandi of gastric disturbance in the production of vertigo, their clinical relationship rests on evidence which is apparently conclusive.

In this connection I desire to present the following case: Mr. S., a farmer, aged 55, was referred to me by Dr. H. A. Deumling, Jan. 22, 1900, complaining of vertigo and stomach trouble, the latter of 1½ years duration. Prior to that time his health had always been good. Shortly after the beginning of the stomach trouble he began to have left-sided tinnitus aurium, which has been a constant feature ever since. A few months later there appeared paroxysms of severe nausea and vomiting, which would begin with intense vertigo and severe aggravation of the tinnitus mostly limited to the left side. These attacks would last several hours, and some of the more severe ones for nearly a day.

In the intervals between these attacks his condition was fairly satisfactory, there being only slight evidence of gastric disturbance with an intensification of the tinnitus occurring invariably within an hour after every full meal. If he ate an unusually large meal the exacerbation of the tinnitus would continue, and in a short time vertigo would supervene, and, finally, vomiting with complete relief of all symptoms, with the single exception of the slight persistent tinnitus. There had been no headache at any time.

---

[*] Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

He had frequently found that a fairly full meal, which he would regard as about what he ought to eat, might not cause any immediate exacerbation of symptoms, but in the course of twenty-four hours the tinnitus would become exaggerated. This had proved to be the case so constantly that taken in connection with the frequently immediate exacerbation of symptoms he had restricted his diet to such an extent that great emaciation had occurred and was constantly progressing. In ten days preceding my first examination he had lost six pounds in weight.

The bowels were somewhat constipated. The dejections contained no pigment whatever visible to the naked eye and were of the type usually, but absurdly, designated acholic. At the time of the paroxysms of vertigo he had to keep absolutely still, in a recumbent position. If he raised or turned his head quickly, or even looked up suddenly, it would produce severe vertigo followed by vomiting. The hearing was greatly impaired, especially in the left ear. The hearing distance of my watch, which should be heard at sixty inches, was twenty inches in the right ear and four in the left. During a few months the tinnitus became less in the left ear, and at this time he could hear much better. Otoscopic examination showed marked thickening and fibroid change in the left tympanic membrane. Tests with the tuning-fork showed that he could hear all the tones from C to C4 with both aerial and bone conduction. The vibrating tuning-fork was correctly located at the vertex or on either side.

Vision was 20/20 in both eyes, without any correction. Ophthalmoscopic examination was negative, excepting that the right field seemed rather congested; but both discs were clear and well defined. The pupillary reactions were normal and symmetrical.

The knee-jerk was very active on both sides; perhaps slightly exaggerated, and there were no Rhomberg symptoms, and no paresthesia or other sensory disturbances. The sexual, bladder and rectal functions were normal.

Urinalysis: Total quantity in twenty-four hours, 400 c.c.; sp. g., 1020; total solids, 18.64; reaction, acid, the acidity 60 degrees; color and odor normal; somewhat cloudy, considerable quantities of light reddish-yellow sediment; no albumin nor sugar; urea, 12 grams; uric acid, .6 grams; ratio of uric acid to urea, 1 to 18; total chlorids, 1.68 grams; total phosphoric acid, .92 grams. bile pigment present and from .02 to .04 per cent. of indoxyl potassium sulphate; no phenol nor acetone reaction.

The fecal matter, although, as already noted, presenting no color indicating urobilin or other pigments, was found by spectroscopic examination to contain unaltered bile in small quantities.

Blood examination: The centrifuge showed 39 per cent. of red cells, indicating a little less than 4,000,000 to the cubic millimeter; leucocyte count, 6000; hemoglobin, 75 per cent., rouleaux formation good.

Ewald test breakfast: The total quantity obtained was 30 c.c., the Gunsberg reaction positive; dimethyl titration showed 15 degrees of free acid indicating .05 per cent. of free hydrochloric acid, the total acidity 30 degrees; the biuret reaction was positive and strong, and the starch reaction also present and strong, indicating defective starch transformation.

The fasting stomach was found to contain considerable quantities of mucus and food debris, the former containing a fungus morphologically identical with actinomycosis. The fungi assumed the radiating form, with club-shaped bodies, numerous granules and, macroscopically, the whitish-yellow spherical bodies characteristic of this growth.

The liver was somewhat tender and slightly enlarged, with irregularities in the contour of its lower border, which, taken together with the putty-colored stools, led me to fear that I might have to deal with a case of actinomycosis involving the liver.

The patient was placed on gastric lavage, colon flushing and general hydrotherapeutic procedures consisting chiefly of hot and cold douches. The improvement began at once, and complete recovery ensued within two months. The only symptom remaining was very slight tinnitus in the left ear, which is sometimes absent for several days. No vertigo or gastric disturbance has been present for several months.

The relationship existing between digestion and the paroxysms of vertigo was so constant as to leave no reasonable doubt as to the causal relationship of the former. Added to this we have the complete disappearance of the vertigo consecutive to stomach treatment. So far as the aural findings are concerned, the case corresponds to a group described by Dr. C. H. Burnett, in which he says the vertigo is the result of chronic catarrhal otitis media. These cases he describes as paroxysmal in character, always associated with tinnitus and a certain grade of deafness, and followed sooner or later by nausea, vomiting, reeling, and falling. It is quite possible, in this case, that without the middle ear disease the vertigo might not have occurred. It seems equally certain, however, and indeed much more certain, that without the gastric disturbance the vertigo also would not have occurred.

From a clinical point of view, therefore, the stomach must be regarded as a necessary, and possibly an efficient, cause of the severe paroxysmal vertigo present in this case. It is reported because of the combinations of gastric and middle ear disease, the probable absence of labyrinthine disease, and the obvious relief of the vertigo as a result of intragastric treatment. In dealing with several hundred cases of chronic gastric disease I have found a considerable number in which vertigo was a more or less conspicuous symptom, developing *pari passu* with the gastric symptom and disappearing as they did. As a general rule, however, the vertiginous attacks have not the fulminating character shown by the group of cases commonly designated Ménière's disease, in which group some writers, L. C. Gray among them, include the vertigoes of external and middle ear as well as those of internal ear disease. In some of these cases of gastric vertigo, however, the attacks are distinctly cyclic in type. In one recent case the patient fell to the ground on several different occasions, and yet the most critical examinations failed to reveal any cerebral or ear disease.

Note—The patient above recorded called at my office about December 15, 1900, and reported that he had been entirely well during the interval since he quit treatment, with the exception of one or two attacks of vertigo of the same type, both preceded by obvious gastric disturbances.

DISCUSSION.

Dr. D. I. Wolfstein, Cincinnati, Ohio—I wish to report in connection with this paper a case which presents almost identical symptoms. The case was referred to me by an ear specialist, after having been treated by physicians, and he had not been able to find anything abnormal in the ear after careful examinations. The symptoms were almost constant, tinnitus aurium with such attacks of vertigo as the essayist describes, except that the attacks were as many as thirty or forty a day. The patient was a city salesman, and his business necessitated driving around through the city. He successfully treated himself after adopting the ordinary methods for mild stomach disorder, lavage, and the giving of an antiacid. He recovered completely and remained so until two months afterward, when he again presented himself with the identical symptoms he had had before. In the interim of recovery, the tinnitus was not relieved. He was given an aloin, belladonna and strychnin pill, and now presents himself for treatment, but he is not in a condition of recovery. These conditions of vertigo and tinnitus aurium make me think that they are probably to be compared with some other conditions we group under the idea of perverted ideas or symptoms that have become cerebral and not attached in any organic way.

Dr. H. H. Levy, Richmond, Va.—I offer my unqualified commendation of the Doctor's exhaustive research in this case; it commends itself to us for the method pursued in regard to the elucidation of the etiology. One thing that he stated was suggestive. From the examination of the urine he determined the proportion of uric acid to urea to have been 1 to 16. Uricacidemia is productive of varied nervous symptoms, and it may not be unlikely that that was a provoking cause of the nervous symptoms in this particular case. It is very common, as all of us know, to see cases of vertigo that we attribute to the stomach and liver. I should say in these cases that there is some defect in the working of the liver. We may have failure of performance of some action of the liver, even if we do not have jaundice. The liver is intimately concerned in the formation of uric acid and urea, and where we find cases of excessive uric acid, the proper process of digestion of the intestines is not taking place, and also excretion is probably imperfect. It is very common to see persons affected with vertigo, who are quite comfortable in the supine position. They are not at all anemic; the blood examination shows that, and the pulse indicates that there is no lack of blood, but they become very dizzy upon rising. Treatment directed to the proper action of the liver, as for instance the administration of hydrochloric acid and strychnin, has afforded complete alleviation of this condition. Another question is whether vertigo may not be due to real ptomain poisoning. I think it sometimes is, but that hinges on one point, namely, imperfect disposition of the food in the alimentary canal. Unless we can limit the patient to one meal a day, we can not tell whether a certain meal is productive of certain symptoms. If we can give the patient one meal, and in six, ten, twelve, fourteen or twenty-four hours, regularly and uniformly, certain effects are produced, then we have a right to say that there are certin ill effects produced by that particular meal. A great many cases of vertigo are simply due to improper digestion.

Dr. Hugh T. Patrick, Chicago—I should like to ask Dr. McCaskey to state a little more carefully the character of the vertigo in this case. Probably I did not get it fully as he read it. It is exceedingly important, in writing of the nature, cause or origin of any case of vertigo, to very definitely define the vertigo itself. I should like to say, for myself, that I have come more and more to look with great skepticism on vertigo of gastric origin and on liver or intestinal vertigo, and symptoms coming under that general head. Where there has been a real turning or rotary sensation, with inability to stand steadily or at all, the cause has ordinarily been found in the ear or somewhere in the cranial cavity, or it has been a case of heart disease, or a bad case of anemia—in other words, something strictly and determinably of organic origin. I do not remember seeing a case of well-defined, unmistakable vertigo of gastric or abdominal origin. A general feeling of lightness in the head, a general feeling of uncertainty and discomfort, which patients describe as dizziness or as vertigo, as well as the cases spoken of by Dr. Wolfstein, approximating agoraphobia, in which the patient is terror-stricken or panic-stricken and can not find himself, are exceedingly frequent, but they are separate and distinct from real vertigo.

Dr. G. W. McCaskey, Ft. Wayne, Ind.—Referring to Dr. Patrick's expression of his own skepticism as to the existence of vertigo of gastric or intestinal origin, I would say that the gentleman simply voices the sentiments of the average neurologist of to-day. This is undoubtedly the trend of neurologic thought, and in reaching a different conclusion I have done so on the basis of a rather large experience with gastric disease. A case which I have not quoted is one among a great many others I have seen—a case in which there was no suspicion whatever, of either cerebral or aural disease; one of the worst cases of gastro-intestinal disease I have ever seen. There was very intense gastric-motor insufficiency. That patient was taken into one of my rooms and placed on a table for examination, and it would take him two or three minutes to get up or lie down, the vertigo was so intense. So far as the adequacy of the gastric or gastro-intestinal causes is concerned, the patients have recovered without exception, and in this one the vertigo remained permanently cured upon curing the gastric disease. We must take into account the conditions to which Dr. Patrick has referred, as associated anemia, etc. —but why do they recover without recovery from the anemia? And why does the vertigo take place in the absence of anemia? I do not think it is fair on the part of physicians or neurologists to assume the existence of cerebral or aural disease, unless they can be positively demonstrated by examination. This case has been observed over a period of three years, and is absolutely well; no return of the vertigo or any development of what might have been at that time latent cerebral or aural disease. It is fair to assume that it does not exist in that case.

As to the character of vertigo, in this case it was a very sudden loss of balancing power. The patient would have fallen if he had not been supported, and when he had once lain down, he could not move his head from one side to the other. He could not look up suddenly without severe aggravation of the vertigo. Here is a case in which this symptom develops with the ingestion of a large quantity of food, and disappears with its rejection. I assume that we can attribute such a series of events one to another. I think the *post hoc* in this instance is fairly demonstrable to be a *proctor hoc.*

There was hepatic disease in this instance. There was bile pigment in the urine and feces, as demonstrated by the spectroscope. The presence of bile in feces is pathologic, not physiologic. The normal coloring matter present in the feces is not bile. There was no jaundice whatever. The only evidence of hepatic disease was enlargement and tenderness of the liver, with bile-pigment in the urine and fecal matter. I did not attach much importance to the large quantity of uric acid. The proportion of uric acid—the ratio—to urea was too large; it was 1 to 18. The absolute quantity was small, only 0.6 gram, which is less than 10 grains and is below the average. Even if it were 20 or 30 grains, I would regard it as a relatively unimportant phase of the case.

Dr. Wolfstein spoke of recurrence. I recognize the pertinence of that point, and I told this patient that, in my opinion, he was not well. He will return to me with this vertigo, because the gastric disease will recur. I confess that it is very difficult to determine the essential pathology of such a case, and yet, at the same time, I am forced by the honest study of the facts in these cases, to the conclusions that gastric disease is an efficient cause of vertigo, and while in this case there was associated aural disease, in many it does not exist, as far as examination will enable us to determine.

HEART TONICS.*

BY JOHN N. UPSHUR, M.D.
RICHMOND, VA.

In discussing the subject of this paper I must at the outset claim the license to consider it in its broadest sense, studying it from the standpoint of the clinician and therapeutist rather than from the technical ground of the physiologic action of drugs.

The term "tonic" should mean, when discussed in this way, the broad principle evolved by the therapy of any remedy, which shall have the power of regulating heart action, whether its irregularity be functional or organic or that modification of its conditions which renders the heart action a source of discomfort or danger to the patient. In dealing with functional disturbances which are the result of impaired reflexes, coming as they most commonly do, from disturbance of digestion or some uterine derangement, the indications for relief are plainly the removal of the gastric or uterine disorder back of the perturbation or irregularity, not forgetting that prolonged and persistent functional disturbance may result in organic change of the walls or valves of the heart.

Again, intelligent consideration of these agents and skilful exhibition must be absolutely based on an accurate knowledge of the pathology of the affection in which a heart tonic is indicated. A conviction that many times an improper drug for the fulfillment of the indications is selected and given, either with no benefit or with directly harmful results, has been the inspiration of this paper.

Selecting those drugs most popular as heart tonics, and most frequently exhibited, I shall consider their physiologic action and then the indications for their therapeutic application, reserving to myself, as I have already indicated, the right to discuss agents which, under a strict classification, are to be considered as cardiac depressants, but yet are, in the broadest sense, indirect heart tonics, because they regulate heart action.

---

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Why not if it be excessive and too strong. I emphasize this point, because it is not a new thing to see digitalis given to relieve a patient suffering from disturbed heart action, excessive in tension, because of hypertrophy—the result of valvular or renal lesion or of long-continued and excessive stimulation of the vagus due to excessive use of tobacco—when really it is emphatically contraindicated, and the truest tonic, calmative and comforting to the patient, is an agent like aconite, nitroglycerin or veratrum viride belonging to the class of pronounced motor depressants.

On the other hand, agents like these, nitroglycerin especially, are frequently exhibited to sustain heart action when strychnin or digitalis may be imperatively demanded to prevent sudden and absolute heart failure.

Digitalis.—Physiologic action is most pronounced in the beginning by slowing of the heart's action, increased arterial tension and lengthening of the diastole. These are due to the stimulation of the vagus, cardiac motor ganglia and inhibitory centers, though some authorities claim its action is directly on the muscular walls of the heart which act with increased power, filling the bloodvessels more perfectly and fulfilling the conditions of a perfectly normal circulation. But continued administration results in greater frequency and diminished arterial tension, due to exhaustion from over-stimulation of the vagus, etc. In the first stage of its action there is a contraction of the arterioles of the kidneys, diminished elimination, consequent on over-stimulation of the vagus, and secondary cardiac depression. As a result of these conditions, digitalis is a remedy of uncertain value, because a secondary condition of depression may result from its exhibition, and at a time when it would jeopardize the welfare of the patient.

To be more explicit, in mitral regurgitation, the lesion in which it is conceded to be most useful, in the earlier stage when we wish to sustain heart action until compensation is established by a physiologic hypertrophy, I question whether the drug can be limited to its first effect until compensation is established; and in the later stage, when compensation fails and the heart is already depressed and exhausted, digitalis is evidently contraindicated. Digitalis is, to say the least, a remedy of transient benefit in mitral regurgitation and may be positively harmful in its ultimate results. But this is the most favorable standpoint from which to consider the drug. In fatty change in the heart walls, the stronger contraction of the heart in systole on the contained blood results in a muscular strain, thus increasing the dangers of rupture of the cardiac wall.

In the threatened heart failure of typhoid fever, benefit must accrue from the exhibition of such an agent as can be continued long enough to tide the patient over the critical period. The heart muscle, as the result of long-continued high temperature and impaired nutrition, is in a condition of granular, degenerative myocarditis. Any agent which stimulates the cardiac ganglia, inhibitory center or vagus under such conditions must be harmful to the patient in the highest degree; and when the exhaustive stage is reached, serious danger of fatal syncope may be expected as a legitimate consequence. Hence in fevers, septicemia and like affections, digitalis and all agents of similar physiologic action are positively contraindicated. Nor is this all: Careful observation has demonstrated that digitalis does not increase pulse tension in pneumonia. It is suggested because of the febrile condition. But another patent fact must be considered, namely, that with the lesion in the lung—hepatization, most probably—the threatened heart failure is the result of exhaustion. The heart tires from an ineffectual effort to keep up the circulation through solidified lung, and the compensatory respiration carried on by the remaining or partially congested tissue does not aerate the blood rapidly enough to save the strain on the tired heart muscle. It is like lashing a foundered horse to force him to renewed exertion of which he is incapable.

Again, in mitral stenosis, benefit is to be expected from the exhibition of digitalis because prolonged diastole allows the ventricle to receive a larger quantity of blood. Its greatest field of usefulness is in lesions of the mitral and tricuspid valves, with their resulting secondary lesions. But in aortic stenosis, the forcible contraction of the ventricle during systole, with obstruction ahead of the column of blood, is risky, because rupture of the heart wall may result. Nor is the danger less in aortic insufficiency. Lengthened diastole permits overloading of the ventricle, and again danger from heart rupture is at the maximum. I believe that it is commonly routine practice to prescribe digitalis or kindred remedies when valvular lesions are detected, without making a discriminating diagnosis, and this ought not to be.

Convallaria.—In its action this drug is similar to digitalis and it is used under similar therapeutic indications. A fact of some importance is that it may be used as supplemental to digitalis. Its advantages over the latter are: 1. It is more strictly limited to the heart. 2. It does not prolong the diastole to the same extent, but slows cardiac action while augmenting the force of ventricular contraction. 3. It is probably free from the danger of cumulative action, and therefore may be given for a longer period. 4. It is probably better borne by the stomach, though the experience of observers differs in this respect. 5. Its diuretic action is not so distinct as digitalis. 6. It is of value in correcting cardiac rhythm. It must, however, be acknowledged that it is not so strong or reliable as digitalis.[1]

Spartein.—This is a true stimulant to the muscular substance of the heart, acting through the cardiac ganglia, and in my hands has been valuable, when the heart walls were flabby and weak. It has been recommended as a heart stimulant in anesthesia.[2] Spartein, too, has the advantage of being slowly eliminated.

Strophanthus.—There is diversity of opinion among observers as to the true physiologic action of strophanthus; some claiming that its effect is less permanent than that of digitalis. If it be given in combination with strychnin, this objection is obviated, and it possesses the advantage of acting on the heart muscle and muscular coat of the blood-vessels, thus avoiding the reaction which comes from exhaustion of the vagus when digitalis is used. I am not, however, prepared to admit, as the result of my observation, that its action is less permanent than digitalis. After compensation has failed, stimulation of the tired heart muscle by strophanthus, while the vagus is still active, is of considerable value. In the threatened heart failure of typhoid fever and the septicemias, given with strychnia, it will be found a very useful agent.

---

[2] Cotton, G. C.: N. Y. Med. Jour., Nov. 26, 1896. Foster's Practical Therapeutics.

Atropin.—Its physiologic action is to stimulate the cardiac sympathetic, the accelerator apparatus of the heart, producing increased frequency and increased tension and at the same time to lessen the inhibitory apparatus. It must not be pushed to the point of exhaustion. Its greatest usefulness is in tiding the patient over an emergency, in cases of sudden collapse and threatened heart failure. Some of the cases of flabby, fatty heart, especially those in which we have bronchorrhea as a sequence of the impaired action of the heart, and in which also there is risk to the patient from threatened stoppage of the heart, and from interference with respiration by the flooding of the bronchial tubes with mucus, are peculiarly benefited by atropin because it deals with both these conditions. A respiratory stimulant as well as a cardiac, it strengthens respiration and stops the effusion of mucus by its drying effect on the bronchial mucous membrane. I think, however, it is always important that it should be combined with strychnin. Potter recommends its use hypodermically in threatened heart failure from chloroform narcosis.[3]

Caffein.—Caffein stimulates and then depresses the cardiac ganglia as well as the cardiac muscle. Its chief field of usefulness is in functional heart affections, or as an adjuvant in those cases of organic heart trouble in which the function of the kidneys needs to be stimulated, to get rid of dropsical effusion. It is not curative in this instance but adds much to the comfort of the patient and aids in prolonging life. I have found caffein, when given in combination with benzoate of lithium and sulphate of spartein, especially useful in the dropsical conditions of parenchymatous nephritis, associated with secondary heart involvement.

Strychnia.—Close clinical observation has constantly increased my confidence in this agent, and demonstrated its reliability for definite results. Not the least part of its adaptability as a heart tonic is that, like other bitters, it is a stomachic tonic also, strengthening digestion and improving assimilation and nutrition. "It stimulates the motor nerve cells of the spinal cord, the cardiac motor ganglia, the respiratory and vasomotor centers in the medulla, and the sensory nerves and their terminal elements. The result is that respiration is deepened and quickened, the action of the heart is increased and the blood-pressure raised."[4] In the enfeebled heart action from chloroform narcosis, it is a valuable remedy, and it has become almost routine practice with me to precede the administration of chloroform by giving, hypodermically, 1/30 to 1/20 gr. of nitrate of strychnia. Its value, administered as a safeguard, will be appreciated, when we remember that death from chloroform is due to paralysis of respiration, or paralysis of the heart, or to the two combined plus the shock of operation. Strychnia directly antagonizes these conditions. In the enfeebled heart of typhoid fever, the septicemias and pneumonia, or in the syncope due to heart failure I know no remedy so potent and prompt to sustain heart action. In functional reflex cardiac disturbance, weakened irregular heart action, the cardiac disturbances of the climacteric complicated by exhausting hemorrhage; in the weakened heart action in the later stage of Bright's disease, after compensation has failed and arterial tension has given way, resulting in an ischemic condition of the blood-vessels; strychnin in all these conditions fortifies heart action. The superiority it has over digitalis and other heart tonics of its class is demonstrated by the fact that there is no cumulative depressant second or third stage. Nor will its ability be disappointing in organic valvular lesions of the heart when the heart muscle needs support in the performance of its function. The fact that it may be pushed for a longer time and gives satisfactory and definite results places it at the head of heart tonics.

Nitroglycerin.—We hear this agent spoken of, and see it mentioned in many articles of current medical literature, as a heart tonic. Experiment has demonstrated that it produces death by general paralysis, especially of the muscular system; and autopsy shows the ventricles of the heart unequally dilated, the right more so, and the venous system engorged with blood. It lowers arterial tension, and in an engorged right heart is useful, combined with strychnia. Physiologically we have languor, nausea, rapid, weak, dicrotic pulse. It also impairs muscular contractility. Its most beneficial action is found in angina pectoris, both true and pseudo. I am persuaded that its use is contraindicated in the weak and impaired heart of typhoid fever, septicemia, and surgical shock. No agent can be safely administered to sustain heart action, and avert death from heart failure whose physiologic action is known to be first, depression of the medullary center, consequent threatened paralysis of respiration and marked paralysis of the muscular system.

Opium.—In conclusion, I would say a word on opium as a reliable heart tonic. The clinical significance of its beneficial action on the weak heart I have seen repeatedly exemplified. When, after a long continuance of typhoid fever, the stage of coma vigil, vasomotor paresis, general, but especially marked in the accumulation of gas in the intestines; feeble, dicrotic pulse; dusky hue of the cutaneous surface, especially the face; in fine, that clinical picture so familiar to us all, and indicative of the great jeopardy of the patient, opium in a commanding dose, repeated in a few hours if necessary, has changed the whole aspect of the case, and proved the pivot on which the case has turned to a prompt and sure convalescence.

210 West Grace Street.

DISCUSSION.

Dr. W. D. Garlock, New York City, said that there is one point which is frequently overlooked in the treatment of weak heart, i. e., the state of the blood. We have a mechanical problem of an engine—the heart—driving a weight of blood through the blood-vessels. If the blood is poor, the required quantity of the blood in increased, and the weight being thus increased, more work is thrown on the heart. If we, by appropriate treatment, improve the quality of the blood, we to that extent reduce the labor of the heart, for the tissues will not demand so much blood for their nutrition.

Dr. Reilly, New York City, asked if the reader had an opinion to communicate as to the value of cactus grandiflora as a heart tonic?

Dr. J. N. Upshur said that his experience with cactus grandiflora had been very slight. He had used it, especially in one condition in which there was a condition of debility, a depressed condition of the heart, the result of excessive use of tobacco. In his part of the country he often sees cases of tobacco heart. He likened it to the fiddler who keeps constantly tightening up the string, until the string snaps. In the same way, the persistent overstimulation of the heart by the tobacco finally leads to heart failure. In the case of a prominent clergyman in Richmond, who did not respond well to strychnin, he had given cactus, but it did not give him as much relief as it should and he finally got relief from strychnin in large doses. We see so many patients who are stimulated too much with tobacco, but none of them will admit that they are slaves to the habit. He has one challenge by which he can prove to them that they are taking too much and are under its stimulating effects. He challenges them to stop using tobacco, for a time, to see what an outcry there will be of the system against the stoppage, and the consequent gain in the pulse-beat after using the tobacco. If you take any machine and constantly drive it from one-third to one-half above its capacity it will break down. In the heart we have the same thing. There is a certain influence of the living tissue against the tobacco, but it will finally break down. The consequence is depressed action of the heart, and especially in young men, and particularly from excessive cigarette smoking. When such a person is taken sick with some serious illness, like pneumonia, then the heart tonics fail us, and they die of heart failure, when they should get well.

---

[3] Potter: Practical Therapeutics, p. 131.

[4] Potter: Foster's Practical Therapeutics, p. 26.

Dr. J. T. Melvin, Saguache, Colo., said that he had used cactus as supplementary to strychnin, but not as a substitute for it. His own experience is that the best results from cactus are obtained when the disturbance of the heart is functional. In all cases in which the disturbance is unconnected with organic disease, we have in cactus a useful agent. In digestive and genital disorders we often have reflex disturbance of the heart, also in tobacco and coffee habits. He gives, in such cases, the fluid extract in five-drop doses several times a day.

Dr. Leonard Corning, New York City, said that he had used strychnin and found it beneficial on a smoker. The only objection is that when using strychnin he smokes twice as much.

Dr. Heinrich Stern, New York City, said that the author of the paper under discussion had omitted any reference to adonidin. In his investigations adonidin proved the very best and the most efficient of the so-called heart tonics we possess. Adonidin is not a mere succedaneum of digitalis. It is true, the physiologic action of both agents is identical to a certain degree. However—and this part he wished particularly to emphasize—adonidin, in spite of its more prompt and energetic action, may be safely administered in such cases where digitalis and the so-called other heart tonics can not be employed at all or only with the greatest caution; such, for example, as fatty degeneration of the heart, pericarditis, atheroma and heart lesions accompanying chronic cases of nephritis. He said he had never noticed a cumulative action of the drug, and in all instances in which he employed it, whether it was administered in the form of powders, tablets, pills or solution by the mouth, or in that of suppositories by the rectum, or by hypodermic injection, it was always well borne. The dose of the drug varies, according to the object desired, from .002 gm. to .01 gm. Those who are interested in the subject were referred to his original article, in *Merck's Archives*, April and May, 1900. He said, too, that adonidin deserves a place right on top of our list of heart remedies.

THE THERAPEUTIC APPLICATION OF THE ORGANIC EXTRACTS.*

O. T. OSBORNE, M.A., M.D.
Professor of Materia Medica and Therapeutics at Yale University; Member of Connecticut Medical Society, Etc.
NEW HAVEN, CONN.

A few years ago we listened with interest, wonder, and often incredulity to a paper on organic extracts, but since that time we have heard so many papers and read so much on the use and abuse of these extracts, that one feels like apologizing for talking on this subject.

We can no longer treat of these internal secretions together, but each one now claims a separate discussion, and if you will bear with me I will try to present a few facts and thoughts concerning the thyroid, thymus, pituitary and suprarenal glands.

Though Schiff had experimented in 1859,[1] he did not impress upon the profession, the scientific value of his experiments on thyroidectomized dogs until 1884.[2] Horsley and other observers[3] have confirmed Schiff's work, and Halsted[4] has shown the interesting fact that removal or injury of a portion of the thyroid can stimulate the rest of the gland to furnish secretion enough for the whole body. In 1878, Ord[5] showed the relationship between the thyroid gland and myxedema. Horsley, in monkeys, and Reverdin,[6] in man, described the symptoms of operative myxedema, while Kocher[7] noted these symptoms of operative myxedema did not occur when the thyroid was removed in old age; a very interesting fact.

Schäfer[8] describes the symptoms of operative myxedema as tremor, mental apathy, unsteadiness of gait, diminution of the cutaneous sensibility, lowering of the temperature, drying of the skin, falling out of the hair, and an increase of mucin in the connective tissue, especially of the skin. These symptoms known to be caused by the removal of the thyroid, are all exceedingly interesting when we realize that a diminished secretion of the thyroid in man can be the cause of similar symptoms and yet the diminution of secretion perhaps not be sufficient to cause an actual myxedema. It is also therapeutically noteworthy that all of these symptoms can be prevented in thyroidectomized animals and men by feeding thyroid extracts.

In 1895 Baumann discovered iodin in the thyroid, which has since been proved to be the only part of the human body in which the iodin is normally contained, and Weiss[9] estimates that the adult thyroid contains .004 of this element, the amount varying at different times and in different localities and at different ages, the greatest amount being found between the ages of 25 and 55.[10]

The feeding of thyroid extract or Baumann's iodothyrin causes loss of weight and an increased nitrogen, sodium chlorid and phosphorus—P_2O_5—excretion and marked diuresis.—Ross.[11] It is very probable that this diuretic action is due to the increased amount of urea excreted, although all of the nitrogen increase is not in urea formation.

Cyon,[12] finding vasodilator fibers in the thyroid nerves and that their stimulation lowers the pressure in the carotid arteries, infers that a function of the thyroid is to regulate the circulation and prevent hyperemia of the brain.

Oliver and Schäfer[13] have shown that the thyroid contains a substance which will cause marked fall of the blood-pressure, and J. L. Smith[14] says that thyroidectomized animals show abnormally rapid reaction to changes of temperature, in other words, show a disturbance of the heat-regulating mechanism. This latter is to me a very important fact when we consider the lack of development of the thyroid in the young child and the child's susceptibility to every change in the atmospheric temperature.

The thyroid also seems to be a regulator of connective-tissue formation, and the less the thyroid secretion in the adult, the greater the connective-tissue growth.

In partial support of the theory that it is the purpose of the thyroid gland to render innocuous certain toxic substances circulating in the blood, is the fact that the urine of animals after removal of the thyroid becomes more toxic than that of normal animals.

So much for thyroidal experiments, but unlike other drug investigations we have the pathology of the thyroid to aid us in formulating the therapeutic indications. In cretins this gland is either absent, very small, or cystic, and the colloid material, the representative of thyroid activity, is absent from most of the alveoli—de Coulon.[15]

---

* Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In myxedema the thyroid is found atrophied and the glandular parenchyma replaced by more or less connective-tissue formation, the colloid material diminished, and the iodin content decreased or nearly absent.

In the beginning and during the activity of Graves' thyroid disease—exophthalmic goiter—there is a hyperplasia of the thyroid parenchyma, and therefore an increased glandular output.[16] Later, which is probably the normal cure of the condition, we may find a fibroid or connective-tissue degeneration, and the gland ceases to excrete in excess.

If any one doubts that Graves' disease is a hypersecretion of the thyroid, he has only to consider that in at least 90 per cent. of all cases this disease occurs between the ages of 20 and 40, or the most active period of the thyroid-gland secretion. Also that this increased secretion, like thyroid feeding, causes loss of weight and that there is lowered blood-pressure, cardiac palpitation, hot flashes, profuse sweating, great mental activity, insomnia, diminished peripheral electrical resistance, which symptoms are the exact antithesis of those of myxedema. Also in explaining many of our neurotic conditions and so-called neuroses, we can but presume that there can be all ranges of thyroid secretion, from sufficient diminution to cause myxedema to the excessive amount which causes Graves' thyroid disease, and hence we may have the thyroid as a cause of many of our cerebral, vasomotor and cardiac functional disturbances.

To sum up the physiological action of the thyroid: It seems necessary for the proper equilibrium of the central nervous system, and perhaps nutrition and development of it; to the proper quantity of mucin that shall appear in the tissues, principally the connective tissues; to regulate the proper amount of connective tissue, especially of the skin; to the proper organization of P_2O_5 for the assimilation into bone salts; and by its vasodilator power, to the proper regulation of the peripheral circulation, thus regulating the heat loss at least and the normal insensible perspiration which, if disturbed, shows, on the one hand in the drying of the skin in myxedema, and on the other hand in the increased sweating in Graves' thyroid disease. Also this gland seems to have some power of regulating the rapidity of the cardiac contractions.

This gland is easily excited to hyper-secretion temporarily by emotion, and normally by menstruation and pregnancy, this probably being the cause of the more or less persistent increased secretion and consequently more frequent hypertrophy in women than in men, and 80 per cent. of all cases of Graves' thyroid disease occur in women. It is also interesting here to note that this gland normally seems to be a cause, if not the cause, of the dilated condition of the blood-vessels of the uterus, periodically allowing the leakage from the blood-vessels, or menstruation.

Also between the ages of 40 and 50 this gland shows signs of overwork, and atrophies more frequently in women than in men, as shown by 80 per cent. of all cases of myxedema occurring in women.

In the normal individual a small dose of thyroid would be little noticed, at least not for a long period, but when large doses of either thyroid extracts, thyroid glands, or iodothyrin are given for some time, there will be nausea and vertigo with increased cardiac action and tendency to increased sweating and diuresis, with possibly faintness, cerebral irritation and tremor, and according to Betmann,[17] an alimentary glycosuria may be produced.

As to the therapeutic uses of thyroid substance, its value in cretinism, myxedema, and operative myxedema requires no discussion, as all of the symptoms are kept in abeyance by thyroid feeding.

The use of thyroid extract in simple goiter is still subject to investigation. Theoretically, we could only expect that thyroid feeding would act in this condition as when fed to any normal individual, and I can not but doubt the special value of thyroid treatment in simple goiter, and think if the treatment was pushed it would do considerable harm, and if any good was done such a case by thyroid extract, it might be just as much benefited by small doses of other forms of iodin. As the size of the goiter will so frequently diminish under varied treatments, especially the iodin treatment, and then relapse and perhaps again diminish, it makes the statistics of any one treatment very doubtful and the subsequent watching of the case very important.

Believing as I do that Graves' thyroid disease is due to a hyper-secretion, the thyroid extract would be contraindicated during the continuance of the active symptoms. Clinically, I believe this to be well borne out, as all of the symptoms, such as nervous excitability, headache, sweating, flushing, sleeplessness, and loss of weight are increased by thyroid treatment during the activity of the disease. On the other hand, we know that this disease tends to recovery, that this hyper-secretion reduces to normal secretion sooner or later in most cases. Also it is barely possible that a hyperplastic gland may take on the next stage, as is so perfectly typical of other organs of the body, and perhaps have connective-tissue formation, and if not actually diminished in size, may have its glandular elements lessened so that we get a condition of under-secretion with the putting on of weight, muscular weakness, and mental sluggishness, in other words, possibly the first stage of myxedema, which goes no farther. These cases will be benefited by thyroid extract.

The rule I wish to suggest in regard to thyroid treatment in Graves' disease, is: If there is cerebral excitement, palpitation and progressive loss of weight, thyroid treatment is contraindicated; if the patient is sleepy, apathetic, palpitation is not bad, has no headache, and is putting on weight, thyroid treatment will probably benefit the case.

Leichtenstern and Wendelstadt[18] were the first to use thyroid in the treatment of obesity, and there seems to be no question that in favorable cases the fat diminishes, but at the same time there is a large increase in nitrogenous elimination. It is probable that every case of over-weight especially after 40 years of age can be reduced by larger or smaller doses of thyroid extract, daily, provided that there are no ill effects from the treatment; but unfortunately there is considerable risk of causing more or less persistent and troublesome debility. The patient may not begin to lose weight for the first two weeks, and then he loses more or less rapidly, from two to five pounds a week, or even more, and it must be remembered that he will continue to lose weight for some weeks after the treatment has ceased. The starting dose should be about 3 grains and perhaps run up as high as 10 grains two or three times a day to get the best results.

The unpleasant symptoms are nausea, loss of appetite, and easily excited heart, with short attacks of palpitation, troublesome weakening perspiration, at times *cold* hands and feet, and a general muscular relaxation and debility, possibly with attacks of syncope, and in one case the writer has seen an epileptic form of convulsive attack which he could attribute to no other cause. These symptoms are very similar to the early symptoms of Graves' thyroid disease, in other words a hyper-secretion of the thyroid.

The loss of weight, as above stated, will continue for some time after the thyroid feeding has ceased, unless the feeding has been given too long. In either case there comes a time when there seems to be no more loss of weight. With the diet the same and the feeding the same, there are weeks during the treatment in which there is no loss at all, but the next week may bring the loss of weight up to the average. For the treatment to be successful, a modification of the diet does not seem necessary. Whether the improvement in weight becomes permanent or not can not be foretold, but the majority of patients who continue their habits of over-eating, or in whose families obesity is hereditary, will quickly again put on weight.

If, as I think possible, one of the factors in causing the over-weight in adults after 40 or 50 is the diminished secretion of the thyroid, especially in women, it would seem physiologically correct that after this weight had been reduced by thyroid feeding, a small daily dose would prevent the recurrence of the fat. In other words, treat the case as we do a cured case of myxedema, only the dose of the thyroid required will probably be less. Thyroid extract has been satisfactorily used in juvenile obesity.[19]

As to the use of the thyroid in skin diseases, we could expect it to cause a better nutrition of the skin and more active superficial circulation and stimulation of the sweat glands, and possibly sebaceous glands, and a consequent increase of the activity of the corium and throwing off of the epithelium, thus getting rid of an old epidermis. This action of the thyroid has been demonstrated to be of practical value clinically in such conditions as dry scaly eczema and in psoriasis.

Although this treatment has come somewhat into disrepute with dermatologists owing to its debilitating properties, I believe that too large doses have been used, and that smaller doses would answer the same purpose and cause no debility. In fact when we consider the amount of secretion which a ductless gland gives to the circulation daily, we can not but see that the use of large doses, except in certain conditions, is entirely unjustifiable.

Thyroid will probably be found to be especially good treatment in the dry eczemas of old age, possibly in the itching due to the drying of the skin at this time of life, and the writer has found it of value in the so-called strumous conditions of young children.

I think very probably that young children with dull heavy features, fat, with flabby condition of the flesh, tendency to mucous discharge from the nose, with persistent cracks and fissures either at the openings of the nares, at the corners of the mouth, or back of the ears, and with recurrent irritation of the skin on the nates, may have diminished thyroid secretion, but not sufficiently diminished to cause a cretin. Such cases I have found to improve under the treatment of thyroid. I have also found enlarged glands in the neck to become normal in size under this treatment.

The fact that the hyper-secretion of the thyroid, as in Graves' thyroid disease, increases the cerebral irritability, causes excitation and even in some few instances mania, and on the other hand the mental hebetude which occurs in cretins and in myxedema, has caused this substance to be used by alienists[20] in cases of insanity.

It is easily supposable that a secretion which has a vasodilator substance and therefore, perhaps, power to regulate the circulation of the brain, might cure functional mental derangements, but we do not believe that it could cure actual cerebral degeneration. In line with this suggestion, alienists have found that a prognosis can often be made in cases of insanity by the results of trial with this treatment. Certainly in cases of melancholia where the brain needs to be excited and stimulated, or in cases of hypochondriasis, thyroid treatment would seem to be indicated, and Starr[21] believes in the use of this drug in the mental disturbances occurring at the time of the climacteric. I have recently had a patient with melancholic hysteria who had not spoken for five or six weeks, who, under the treatment of small doses of thyroid, began to act more like herself and answered questions put to her after five days of the treatment. During these five days absolutely no other treatment, method or suggestion was used.

The thyroid function being so closely allied to the menstrual function, it can not but show disturbance at the cessation of the latter, i. e., at the menopause. If the thyroid should rapidly diminish its secretion at this time, we have the condition of myxedema which occurs, as above stated, in 80 per cent. of all cases in women. If the thyroid at this time gradually diminishes its secretion, we probably have a most comfortable establishment of the menopause. If, on the other hand, as is fairly supposable, it does not diminish its secretion synchronously with the stoppage of the menstruation and therefore relatively hyper-secretes, we have all of the disturbances of hot flashes, nervousness, palpitation, etc., which are so characteristic of many women during the climacteric, which condition I believe should not be treated with thyroid. If, on the other hand, there is a marked putting on of weight at this period, we probably have too rapid diminution of thyroid secretion and small doses of thyroid extract would probably be good treatment.

As the thyroid atrophies in old age, the question occurs: Is it one of the factors in producing the conditions present in old age?[22] It is not supposable that increased blood-pressure might be due to diminished thyroid secretion and therefore diminished dilator power, and that the suprarenal with its blood-pressure raising power has now full sway, and as a consequence we get the diseases and conditions due to increased blood-pressure, such as endarteritis and all of its manifold consequences. Also the diminished secretion of the thyroid can increase connective-tissue formation and therefore sclerosis in various parts of the body, as we see no exaggerated myxedema. Also is not the drying and wrinkling of the skin in old age due to this same diminished secretion? Certainly it would be worthy of trial to see if with small doses of thyroid we could keep the blood-pressure down and render the dangers of atheroma more remote.

Bell's[23] suggestion that carcinoma of the uterus developing at the time of the menopause, as it most frequently does, is due to diminished thyroid secretion and that the growth is retarded by thyroid feeding, is certainly very interesting. As carcinoma, and especially the epitheliomatous variety, is largely a condition of middle and later life, and as we know that a wart or irritated spot, either fissure or cicatrix, becomes liable to carcinomatous growth most frequently after 40, the possibilities of thyroid treatment perhaps tending to prevent recurrence after extirpation of the local lesion, I believe should certainly be considered.

Thymus.—As this gland atrophies in childhood and disappears after puberty, it is probable that it performs some important function in the development and growth of the young child. If it performs any other function, some other gland or glands evidently assume such work after the age of puberty.

We know little of the physiological action of the thymus gland preparations, although Svehla[24] found that venous injections of extracts from this gland caused acceleration of the pulse by direct action on the heart, and the lowering of the blood-pressure by paralysis of the vasoconstrictors.

Good clinical results from thymus feeding in Graves' thyroid disease in cases where the thyroid treatment caused an increase of the symptoms, would seem to show that any vasodilator substance contained in the thymus was not absorbed from the stomach, but Cunningham[25] has demonstrated that thymus tissue can modify the acute cachexia in thyroidectomized dogs as well as the thyroid treatment.

Mendel[26] has lately proved that thymus gland both in man and animals contains no iodin, and traces found in any given specimen are as accidental as are traces found in any other part of the body outside of the thyroid. The thymus gland contains a large quantity of nuclein, and hence a large amount of phosphorus.

The pathology of this gland is but little known, neither do we know what relationship some of the earlier functional diseases of the infant may bear to it, such as rickets. So-called strumous conditions of young children are perhaps related to malfunction of the thyroid more than to the thymus.

The use of thymus extract therapeutically as yet is empirical. The writer has given the thymus treatment of Graves' thyroid disease a careful trial, and feels convinced that it is often of decided value, but that it is not curative.

Kinnicutt's[27] report of a trial of thymus in pulmonary tuberculosis is certainly suggestive. If the thymus has something to do with the formation or the preparation of the salts for bone growth, it may furnish earthy salts in an assimilable form for the natural cure of tuberculous deposits, at least it may work similarly and perhaps better than hypophosphite treatment. I believe that the subsequent loss of weight after the primary gain in Kinnicutt's cases may have been due to too large doses having been given. As the thymus is so rich in nucleins and phosphorus, it could be used as a substitute for any nuclein treatment.

Pituitary Body.—Not only [illegible] and hystologically, but also [illegible] d is divided into two parts. The anterior part or hypophysis is decidedly glandular, and resembles thyroid tissue. The posterior lobe or infundibulum is largely composed of nervous elements, and Howell[28] has found that it is this part that furnishes an extract which when injected into a vein will raise the blood-pressure and increase the heart's action. This constrictor action of the blood-vessels is a peripheral one.[29] The hypophysis has been found not to furnish any such secretion.

Pathologically we have not yet separated the consequences of the disease of one part of the gland from the symptoms due to disease of the other part. Physiologists[30] have simply shown that when this gland is removed from cats and dogs, death occurs with symptoms not unlike those of thyroid extirpation, which symptoms are ameliorated by injections of pituitary extract.[31]

The pituitary body is, I believe, always diseased in acromegaly. I believe that acromegaly is probably in the beginning always a condition of giantism; in other words, *sooner or later in every case of giantism the condition of acromegaly or asymmetrical growth will more or less markedly develop.* I believe that the pituitary furnishes a secretion which has something to do with the normal growth of the body, and that giantism is due to a hyper-secretion of the pituitary, and that acromegaly is due to a disordered secretion of this gland.

In well-marked cases of acromegaly, the pituitary is generally found in an adenomatous or sarcomatous condition or in cystic degeneration. Reported cases of tumor growths in the sella turcica without symptoms of acromegaly probably had normal secretion furnished by some portion of this gland, as has been so many times instanced in tumors of the thyroid, pancreas and suprarenals.

The relationship of the hypophysis to the thyroid gland we do not know, but it is interesting to note that in many cases of thyroid disease the hypophysis is hypertrophied, and also in most cases of acromegaly, I think always, the thyroid is found enlarged.

I have tried pituitary feeding in three cases of acromegaly. In the first case the disease was in the very last stage, and as I treated him at a distance, and as he died in three or four months after I first saw him, I was unable to note the results of the treatment. In the second case the persistent headache and a considerable amount of the hypertrophy of the lips, hands and feet disappears under the pituitary treatment. If the pituitary is stopped, these symptoms again return to again disappear on return to the treatment. This case has also been greatly improved in muscular power since beginning the pituitary tablets. The third case, which is in the beginning of the condition, although the symptoms are well marked, is in the case of a boy 15 years old, who has been a semi-idiot all his life, and has lately grown enormously, and gives all of the external marks of acromegaly. About a month ago he developed intense and persistent earache, but examination of the ear could give no cause for such pain. I then began pituitary treatment and the pain has entirely disappeared, whatever this may mean.

It is fairly supposable that with this treatment in acromegaly we can prevent the continued growth of the body and the subjective symptoms of headache, neuralgia, muscular weakness, etc.

Suprarenal.—In 1856 Brown-Séquard[32] showed that removal of the suprarenal bodies from animals caused them to die with symptoms of shock, but that feeding of suprarenal tissue to such animals prolonged their lives, but did not prevent death, this being a different result from that obtained in operative myxedema, where thyroid feeding will prevent death. This is in perfect harmony with the later experiments which show that all of the active principles of suprarenal are not absorbed from the stomach and intestines. Later experimentation showed that if the suprarenals were injured by crushing[33] symptoms similar to Addison's disease will develop.[34] Addison, as early as 1855, pointed out the relationship between pathological conditions of the suprarenals and profound anemia with brown pigmentation of the skin and mucous membranes.

Schäfer and Oliver[35] were the first to show that the medullary part of the suprarenals contained an element which, when injected intravenously, would raise the blood-pressure higher than could be accomplished by any other known substance. Moore and Purinton[36] seem to have proved that this crude medullary extract is many times more powerful than any so-called pure product yet obtained.[37] They also showed that no blood-raising effects could be obtained from suprarenal administration by the mouth, although this is denied by other observers.

It is interesting to note that this active blood-raising principle is absent from the suprarenals of the human fetus,[38] although we do not yet know the exact age at which this gland furnishes such a secretion.

Boruttau[39] says that when dilatation of the arterioles has been caused in the muscles by their activity, the suprarenal secretion causes vasoconstriction, especially of the splanchnic system, which gives compensation and protects the brain and spinal cord from anemia, as the thyroid gland protects the brain from hyperemia. This may be an explanation of the sudden stupefying hyperemia which occurs when severe and violent muscular exercise is suddenly stopped, as is seen so many times in the crew of the racing boat after the finishing point has been passed.

The literature on the subject of the relationship of Addison's disease to the suprarenals is vast,[40] but we have Addison's disease with degenerated suprarenals and with intact suprarenals, and extensive degeneration of the suprarenals without Addison's disease, showing, like the relationship of diabetes to the pancreas, that there may be several functional or pathological causes for the condition, one of which seems to be unquestionably the disease of the adrenals. This has been well pointed out by Adami.[41] It is interesting to note that in Addison's disease with degeneration of the suprarenals an extract of this gland is devoid of any blood-pressure raising element.

Through Dr. Bates'[42] and Dr. Swain's[33] efforts, the action of suprarenal extract in the eye and nose, respectively, is pretty generally understood.

The writer has had repeated success in aborting follicular tonsillitis by cleansing the tonsils with a saline solution, swabbing with peroxid of hydrogen, and then spraying with suprarenal, and repeating this treatment in twelve hours. The congestive stage of acute urethritis will also be benefited by injections of suprarenal solution. The strength of this solution for local application on the mucous membranes varies from 5 to 10 grains of the desiccated suprarenal to a fluid dram of water.

While the local use of suprarenal is positive, the results of internal administration of this gland are still, in my opinion, problematical, except for the possible absorption of other constituents of this gland than the blood-raising principle. Certainly in Addison's disease suprarenal extract should always be administered for the possible good from the elements of the gland which may be absorbed.

Reasoning by analogy from what we know of the action of the thyroid, we can believe that the secretion from the suprarenals could be so decreased as to give typical Addison's disease, or any degree between the normal and that degree of diminution, and give symptoms accordingly. Also it is reasonably supposable that these glands could furnish a hyper-secretion similar to a Graves' thyroid disease when the symptoms, instead of being those of vasodilatation as in the latter disease, would be of persistent high blood-pressure. It is barely possible that a hyper-secretion of this gland is one of the causes of general arterio-sclerosis and gout.

Moderate feeding of thyroid extract in these conditions, as stated under thyroid, not sufficient to produce much loss of weight; in other words, in very small doses, might be a physiological antagonist of no mean value in preventing trouble from high blood-pressure.

Unfortunately I do not find that we can raise the vascular tone or combat cardiac weakness with suprarenal extract given by the stomach or hypodermically. On the other hand, strong solutions of it should be used for any capillary bleeding surface that can be reached, such as the stomach, large intestine, rectum, bladder, vagina, and perhaps uterus, for mucous membrane congestion, cancer, etc. From the uterus or bladder I should advise its being washed out in a short time on account of the decomposition of the suprarenal extract which soon takes place.

Tetanus Infection Through the Nose.—Experiments have been reported by Thalmann, from the Leipsic Institute of Hygiene, in which it was found impossible to induce tetanus infection through the sound or even the diseased alimentary canal or urinary passages, but that nasal lesions afforded favorable conditions, also catarrh. Tetanus germs or toxins can be inhaled without infection if the air-passages are sound. In idiopathic tetanus in man, therefore, he suggests (*Berliner klin. Woch.*, January 28) that the entering point of the infection should be sought for in the nose.

TREATMENT OF ADDISON'S DISEASE.

WITH CASE.*

JOHN V. SHOEMAKER, M.D., LL.D.
Professor of Materia Medica, Therapeutics and Clinical Medicine in the Medico-Chirurgical College of Philadelphia.
PHILADELPHIA.

On Nov. 11, 1898, a lad, 19 years of age, came under my care in the out-patient department of the Medico-Chirurgical Hospital of Philadelphia. The history which he gave was rather indefinite and incomplete. He seemed to be an unobservant youth and was probably rather below the average in intelligence, although this slight deficiency may have really been due to the disease with which he was afflicted. He was a mill operative by occupation. His weight at that time was 122 pounds, and he was about 5 feet 5 inches in height. He stated that within no long period he had lost about 5 pounds. The lad belonged to a tuberculous family and his mother had died of pulmonary involvement when he was about one year old. The patient gave a vague account of having had chills about a year previously and at the same time he suffered from pain in the back and limbs. He had not received any injury. About ten days before he presented himself for treatment he had experienced an attack of nausea and vomiting. There was also some cough. Nevertheless, he did not realize that he was seriously ill, thought himself as strong, or nearly as strong, as ever and went to work every day. His pulse was 102 and rather weak, but not extremely so. At this time he complained of lumbar and abdominal pains. He was decidedly nervous. The apex of the heart beat tumultuously against the chest. The face of the patient was of a very pronounced dark reddish-brown, or bronzed, hue. Even the hair was dry and of a similar tint. Discoloration of the skin had existed for a year. It first appeared as dark blotches upon the forehead, whence it spread to the cheeks and other parts of the face. The blotches gradually extended and became confluent, until finally the bronzing was entirely symmetrical. No other portions of the body were thus affected, except the forearms and hands. With the exception of the discoloration there were no other alterations of the surface. The trunk and lower limbs were of a peculiar deep-yellow color. Upon the mucous membrane of the mouth were some small purplish spots. In other respects the mucous membrane was pale and indicative of anemia.

Examination of the sputum and urine threw no light upon the case. The former contained no tubercle bacilli. In the urine were found some pus-cells—leucocytes; numerous crystals of calcium oxalate; some epithelium, probably from the pelvis of the kidney, though possibly from the bladder; a few shreds of mucus; one or two spermatozoa; bacteria, and a few yeast plants.

Diagnosis.—The conspicuous and very peculiar discoloration of this lad's skin furnished a clue to the diagnosis. It was of that distinctive hue which, when once seen, can never be forgotten. The color was that of bronze, that is a deep brown with a tinge of red. It resembled that which may be seen in a machinist's face after a day of toil by the furnace, discolored under the influence of heat, soot and metallic particles. The patient's employment, however, was of a very different kind and did not expose him to such sources of temporary discoloration. The pigmentation, moreover, was indelible and located in the organic substance of the integument.

A disease which produces an excessive deposit of pigment in the rete mucosum is chloasma. This affection of the skin may be due to local or constitutional causes. The latter variety, known as symptomatic chloasma, may depend upon anemia, chronic malaria, tuberculosis, cancer, or chronic disease of some important viscus. Such cases, consequently, present signs and symptoms pointing to impairment of general health and stamping the malady as much more serious than a mere disease of the skin. Symptomatic chloasma is, however, much more common in women than in men. It is associated particularly with altered conditions of the sexual apparatus. It is witnessed in pregnancy and utero-ovarian disease. Our patient was too young to be the victim of carcinoma. It is true that malignant disease attacks the youthful in rare instances, but no form of abdominal growth could be detected and no sharp pain existed. The characteristic hue of cancerous cachexia is a shade of yellow. Chronic malaria likewise imparts a sallow tinge to the skin. Although country people, originally sunburned, acquire a singular hue after having long been sufferers from malaria, yet the surface never assumes that bronzed aspect so noticeable in the patient whose case I describe. Patches of chloasma are generally of an irregular outline; the color may exhibit all shades from light-yellow to nearly black. In fact, the pigmentation may be variously colored on different parts of the same person. Idiopathic chloasma may affect robust individuals and simply present itself as an abnormal distribution of pigment in the Malpighian layer of the skin. Symptomatic chloasma is preceded or accompanied by symptoms denoting serious constitutional impairment.

A bronzed discoloration of the skin is occasionally encountered in exophthalmic goiter, abdominal tuberculosis, diabetes, cirrhosis of the liver and abdominal tumors. These various affections, however, could all be eliminated. There is a condition known as "vagabond's disease," in which the skin assumes a dark-brown shade. The increased deposit of pigment simply occurs in consequence of long-continued irritation by pediculi and scratching of the skin. This discoloration of the surface is not infrequent among tramps.

The prolonged administration of arsenic may produce a diffuse pigmentation varying in hue from brownish-yellow to deep brown. In such instances we should either perceive, or should obtain a history of, other evidences of arsenical intoxication and the patient should have been a victim of some chronic affection, such as malaria or a disease of the skin for which arsenic had been prescribed. This history does not correspond to that of the present case. The indelible stain of the skin and mucous membrane caused by silver when given for too long a period need only be mentioned. The discoloration of argyria is a bluish-gray and bears no likeness to the dusky hue observable at a glance in the subject of this paper. A bluish line due to deposit of silver is also seen upon the gums and mucous membrane of the mouth.

Chloasma generally occurs in patches, although these may extend and coalesce until large tracts are involved. As a rule, however, the discoloration is not as diffuse as in the case of which I speak. After having excluded other sources of discoloration, the diagnosis of Addison's disease was made. I have, indeed, witnessed some cases of chloasma in which the pigmentation was so diffuse that they had been mistaken for Addison's disease by experienced observers. Even in such extreme instances, however, minute inspection will reveal traces of demarcation which originally separated patches of disease from the healthy skin. When the bronzing is decided it is not, in fact, usually difficult to recognize Addison's disease. The task of identification is not so easy, however, when this distinctive discoloration is absent. There are some clinical features which justify us in suspecting the existence of Addison's disease prior to the appearance of the pigmentation. One of these is marked and progressive anemia in the absence of the usual causes of that condition of the blood. The conjunctivæ and other mucous membranes are decidedly pale. There is, furthermore, a debility so extreme as to cause syncope upon the slightest exertion or even when the patient is at rest in bed. The power of resisting fatigue is almost absolutely lost. The tracings of Mosso's ergograph show the curve falling away suddenly, differing altogether in this respect from other wasting diseases, even from pulmonary tuberculosis. From leukemia and pseudoleukemia the early stage of Addison's disease may be distinguished by the absence of enlargement of the spleen and lymphatic glands. Other symptoms suggestive of Addison's disease are palpitation of the heart, dyspnea, loss of appetite, nausea, vomiting, epigastric pain and other evidences of gastrointestinal disturbance.

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Etiology, Pathology and Pathogenesis.—Addison's disease results from lesions which interfere with the functional activity of the suprarenal glands. These ductless bodies doubtless perform a function important to the nutritive processes. When both are removed from frogs the animals perish, although if one is left in place the subject of experiment survives without hypertrophy of the gland which is spared. The removal of one gland from guinea-pigs is often fatal and ablation of both always causes death, according to Brown-Séquard. The adrenals are highly organized structures, abundantly supplied with blood-vessels, lymphatics and nerves. Swale Vincent[1] writes that the adrenals are regarded by the best authorities as double glands, the medullary portion being derived in some way from the sympathetic system and the cortical substance being related to the reproductive system. Both the cortex and medulla are composed of glandular tissue. The organs are supplied by the solar and renal plexuses. In the majority of autopsies of patients who died of Addison's disease fibro-caseous lesions due to tuberculosis have been found in the suprarenal bodies. In other cases the glands have undergone simple atrophy. In a third class there was interstitial inflammation, leading to atrophy. In some instances malignant disease had invaded the capsules; in others they contained extravasated blood. Finally, in a certain number there was no lesion of the suprarenal bodies themselves, but the semilunar ganglion was compressed or inflamed. This disease of the sympathetic may have led to atrophy of the adrenals. M. Raymond, in March, 1892, reported to the Medical Society of the Hospitals, the case of a woman, 27 years of age, who died from Addison's disease. In front of the spinal column was a hard, bosselated ganglionic mass, which extended from the diaphragm to the promontory of the sacrum. The right semilunar ganglion was adherent to the ganglionic mass; on the left side the structures were fused. The right semilunar ganglion was sclerotic; the nerve cells were pigmented and vacuolated; some were atrophic. The spinal cord and suprarenal capsules of both sides were intact. The relationship between the sympathetic system and the suprarenal glands is also shown by the fact that stimulation of the splanchnic nerve stimulates the activity of the glands under consideration. Tumors in this situation, however, do not always give rise to the symptoms of Addison's disease. Vincent concludes that the medullary substance of the suprarenal glands contains an active toxic principle specific to themselves and found in no other tissue. Concerning the physiological function of the adrenals two theories have been advanced. A French school of observers argues that the office of these organs is to destroy the toxic substances which accumulate in the blood as a result of the tissue changes which go on in the body. On the other hand, Oliver and Schaefer, as a consequence of their experiments and studies, believe that these organs elaborate a secretion which is taken up by the blood and is of importance to the nutritive processes of the body. They conceive that the internal secretion has a direct influence upon the muscular tissue, both of the striped and unstriped variety. Professor Howell, of Johns Hopkins University, indeed, accepts the hypothesis fully, and in a paper read before the New York Academy of Medicine, in April of this year, states that it has been demonstrated conclusively that the adrenal vein contains more of the secretion than the other veins of the body. Swale Vincent suggests that the two theories are not so antagonistic as has been usually believed, and that the secretion of the capsules may destroy waste products of muscular metabolism and may also form an active material by means of which an increased muscular tone is produced.

It has been found experimentally that the intravenous injection of suprarenal extract causes a very remarkable constriction of blood-vessels by its direct influence on muscular fiber. This action occurs even when all the nerves leading to a part are cut. Contraction of the caliber of the arterioles causes an enormous rise of blood-pressure. The muscular substance of the heart is also directly stimulated. The decided rise of arterial tension was confirmed by Prof. Isaac Ott, in his valuable experiments relative to the animal extracts, performed in the physiological laboratory of the Medico-Chirurgical College, his subjects being rabbits. Large doses of the extract excite the pneumogastric center, the consequence of which is that while the auricles continue to beat, the contractions of the ventricles are arrested. Other effects of these injections are paresis, paralysis, hematuria, hemoglobinuria, convulsions and low temperature, the paralysis being of central origin. It is thought that the vasoconstrictor action is probably due to the substance lately isolated from the medullary glandular substance by Abel, and termed epinephrin. Whether the central effects are caused by the same principle is as yet unknown. The experimental evidence appears to indicate that a healthy condition of the suprarenal glands is essential to the nutrition of muscular tissue and serves to explain the extraordinary debility characteristic of Addison's disease, in which the functions of those glands are inhibited.

A second point of clinical and pathological interest relates to the source of the coloring matter deposited in the skin and mucous membranes of patients suffering from Addison's disease. Pfoerringer[2] has recently reported a case in which he particularly studied the abnormal pigmentation. Nothnagel, Riehl and von Kahlden had already referred the origin of the pigment to the blood. Pfoerringer found in the capillaries supplying the papillary layer of the derma collections of pigment granules, some of which were free and others were situated in the interior of leucocytes. This author hesitates to draw any conclusions in reference to the manner in which pigment is produced. In this connection MacMunn's experiments and conclusions are interesting and suggestive. This author believes that the function of the adrenals is to select from the blood effete pigments with their accompanying proteids, viz., hemoglobins and the histohematins. This points us to their origin in the iron-bearing and oxygen-bearing erythrocytes, or red corpuscles of the blood. Consequently, disease of the adrenals themselves or, possibly in some cases, suppression of their function by disease of the great abdominal plexuses of the sympathetic, allows these pigments to remain in the blood unaltered, from which they are deposited in the skin and mucous membranes. It assists us also to comprehend the anemia which accompanies the disease.

In view of all such facts and investigations how are we to explain the case reported in 1896 to the French Congress of Medicine, by Dr. A. Rispal, of Toulouse? The patient was a man, 24 years of age, healthy until ten months previous to death, during which period he became afflicted with pigmentation of the skin and mucous membrane, progressive asthenia, and gastro-intestinal difficulties. At the autopsy there was no visceral tuberculous lesion; there was said to be congenital absence of both suprarenal capsules; the branches and ganglia of the abdominal sympathetic nervous system were entirely unaffected. Dr. Rispal stated that he had found a record of two similar cases. Is it possible that in these cases there were accessory glands which had escaped notice at the autopsy?

Treatment.—Until a few years ago the treatment of Addison's disease was most unpromising. We stood in its presence almost utterly devoid of hope. It was formerly the custom to administer iron, arsenic, strychnin and other reconstituent remedies with the view of making a favorable impression on the blood and nervous system, but it seldom exhibited any efficacy. Agents for the relief of vomiting, diarrhea, pain and other symptoms were given according to indication. Now and then a case may have been benefited. A few are said to have recovered. I find the record of a case presented by Dr. Neumann[3] to the Berlin Society of Internal Medicine. The patient was a man, 57 years of age, who had been suddenly atacked, fourteen days before he was brought to the Moabit Hospital, by somnolence and weakness, with bronzing of different parts of the skin and mucous membrane. The patient was treated by means of the continued current and iron. The man gradually, though slowly, improved and it was not until two years from the beginning of the attack that he was able to remain out of bed all day. He then began to recover rapidly and during the following year he was able to resume his occupation. The skin gradually grew paler, the spots disappeared and at the date of the report, six years after his return to work, the color was normal. This fortunate result, however, can only be looked upon as very exceptional. Guided by the analogy between ductless glands and the brilliant effects of organotherapy in myxedema and cretinism, it was proposed that an analogous method should be attempted in the treatment of Addison's disease. The idea was advanced that the use of suprarenal extract might be found to have a beneficial influence in the last-named malady. Accordingly, it was determined to make use of the extract of the adrenals in the case of which I now write.

In view of the marked asthenia, with the tendency to dangerous syncope, which are such prominent features of Addison's disease, this patient should, either at his own home or the hospital, have been confined to his bed. In this respect, however, we could not control our patient. He was a poor, working lad and felt himself obliged to remain at his employment as long as his strength permitted. Moreover, he did not realize the gravity of his condition. To him it seemed rather a matter of curiosity that his skin should be turning so dark. As the most promising means at our command, he was immediately placed upon the suprarenals in the form of an extract. Each tablet contained 5 grains. Of these two were given each day, and the number was gradually increased. Under this treatment he began to improve. On Jan. 6, 1899, he was again brought before the class and it was noted that the nausea, vomiting and cough had disappeared, while the discoloration of the skin semed less decided. On January 20 the report was still favorable. The bronzing was thought to be a shade lighter and the general condition was fairly good. This encouraging progress, apparently in response to the treatment, continued until the beginning of March, 1899, that is, for about three and a half months. During the first five weeks of this period the patient gained 6 pounds in weight and improved a little in strength. There was considerable amendment in the state of his digestive apparatus. Unfortunately, this amelioration was not destined to a long duration. The youth was suddenly attacked by severe pain in the left part of the epigastric region, extending into the left hypochondrium and around into the back. At the same time there was almost incessant vomiting, which was much aggravated when either solid or liquid food was taken. The patient lost flesh rapidly, medicine was without avail and at the end of the third day his sufferings were ended by death.

Post-mortem Examination.—The body was very much emaciated. The areas of discoloration were of a pronounced bronze hue, as has been described in the foregoing history. The right and left pleuræ and the pericardium were normal. The heart was slightly smaller than normal. There was no disease of the valves, but the myocardium was somewhat soft and flabby, showing marked fatty degeneration. The left lung was crepitant, with some hypostatic congestion at the base. The apex showed a few small encapsulated tubercular areas. These did not appear to be active, while in close proximity were evidences of a previous inflammation, possibly also tubercular in character. In the apex of the right lung were several sclerotic areas which had formerly been of the active tubercular type. The liver was fatty and of about normal size. The spleen was unaffected.

The suprarenal glands were only slightly enlarged. On section it was found that they had undergone more or less change throughout; some portions were hard while in others caseous degeneration was quite marked.

The stomach and intestines were normal. The right kidney was slightly enlarged and congested. The left kidney was about two-thirds the normal size; its pelvis was large; the left ureter was much thickened and of double the normal caliber. The opening of the ureter into the bladder was also very large, being at least thrice the natural size. No obstruction was observed in the ureter to account for this peculiar condition. The glands of the mesentery were likewise enlarged and showed caseous degeneration on section.

Remarks.—From the findings of the autopsy it would appear probable that there had originally been a primary tubercular process in the apex of the right lung and that this had healed. The suprarenals were subsequently involved and implication of the left lung followed, although it is possible that the condition in the suprarenals might have been secondary to the disease in the right lung and have remained latent for a time. The lesions of the right lung were certainly old.

This case agreed with the majority in being of tubercular origin and nature. The suprarenal capsules were not enlarged so decidedly as in most instances. The semilunar ganglia were removed for microscopical examination. The small size of the heart was also observed in a case under the care of Dr. F. Buzzard[4] at the Northampton General Infirmary. The patient was a man of 40 years and the suprarenals were extensively destroyed by tubercular disease. The heart was so small that it was rather to be compared to that of a child of 14 than of an adult.

The result of the treatment of Addison's disease by ingestion of glandular extract is by no means so uniform and satisfactory as that of myxedema. The evidence is, indeed, of rather a conflicting character. In some cases improvement has taken place; in other instances the method has failed. In a series of cases treated in this manner Oliver reported 6 cured and 22 improved. Professor Osler[5] has described the case of a man who had exhibited symptoms of Addison's disease for two years and whose sputum contained tubercle bacilli. Notable improvement occurred from the use of suprarenal extract. At the end of five months he had gained 19 pounds, was active and vigorous. The pigmentation, however, was unaffected. Three months later he remained well and was free from cough. I am not informed as regards the subsequent history.

Dr. L. W. Schwab[6] observed the extremely rare occurrence of two cases in the same family, which was free from tubercular tendency. The patients were brothers and resembled each other closely in habits and temperament. One of these was treated by extract of the gland for two weeks, but the agent had to be suspended on account of other symptoms. In a case described by Dr. C. W. Suckling[7] the same plan of treatment was followed by a very satisfactory improvement. The patient was a man, 40 years of age, who for three months had frequently fainted, and for seventeen nights consecutively had even fainted while in bed. The man suffered from nausea, great prostration, pigmentation and leucoderma. He was given tabloids containing 5 grains each of suprarenal gland substance, beginning with two and gradually increasing as long as they caused no ill effects. After taking them for a month the patient was no better and still fainted. The quantity was again raised until he was taking 35 capsules daily when he complained that they caused pain in the back and made his tongue sore. He had, however, gained strength. The remedy was continued, but in smaller doses. At the end of the eighth month of treatment he reportd that he had not fainted for six months. Thirteen months after he first came under observation the man was perfectly well. The pigmentation and bleaching were almost gone. The pulse was normal and he could do a heavy day's work.

No conclusion could be drawn from the interesting case published by Dr. Gilbert Tyson Smith,[8] as the patient was already in a desperate condition when first seen. A woman, 46 years of age, but looking much older, had been ill for two weeks prior to coming under Dr. Smith's observation. Pigmentation was not present until the sixth day of attendance and she died on the eighth. The woman was doomed and nothing could have saved her life. The case was remarkable by reason of its rapid course. At a meeting of the Medical Society of the Hospitals, M. Béclere[9] exhibited a patient, 28 years of age, who, in addition to pulmonary tuberculosis, had for three years presented signs of Addison's disease. The patient had been treated by means of suprarenal glands by the mouth and subcutaneous injections of a glycerin extract of the glands. The woman was benefited and at the end of three years the discoloration had almost entirely disappeared. The general condition was very good. At the same meeting M. Widal spoke of a case in which decided, though temporary, amelioration resulted from the same mode of treatment. The patient gained strength but the pigmentation was unaltered. M. Haymen also referred to a case in which there was temporary improvement without any change of color. Grainger Stewart encountered a case in which suprarenal extract was ineffectual. Dr. Middletown, of Glasgow, writes of one case in which there was some diminution of pigmentation from the use of the extract of the gland.

My own patient, whose case forms the foundation for this communication, was rather younger than the average sufferer from Addison's disease. This malady occurs most frequently in men and generally between the 20th and 40th year of life. Addison's youngest patient was 24 years of age. The affection is rare, but not altogether unknown among children. In an inaugural thesis on this disease among children Dr. H. Dezirot states that one case has been observed in a babe of seven days, and one in a child of 3 years. Osler mentions one in which the disease was congenital and the child lived eight weeks; the adrenals were large and cystic. The disease does not commonly develop among children until about the age of puberty. As among adults, most juvenile patients are male. The affection generally begins with ambiguous and insidious symptoms, but without pigmentation. Darier witnessed pigmentation as the first symptom in a child of 10. Addison's disease sometimes begins in young subjects with convulsions, chorea, chlorosis and heart trouble, and is often preceded by tuberculosis of the lungs, kidneys, glands or joints. Pigmentation usually occurs at the end of several months. In six of Darier's cases among children ingestion of suprarenal glands produced temporary improvement in two, but both patients eventually died of the disease. In three cases there seemed to be slight amelioration. The results of organotherapy would, therefore, appear to be as doubtful among children as in adults. Dr. Bury[10] has described a case of Addison's disease which had existed for a year in a child of 13. The surface was deeply and universally discolored. This patient was given a glycerin extract of the gland, but with no effect, as she died nine days after coming under Dr. Bury's care.

In contrast to the marked bronzing which occurred in my patient there was but slight discoloration of the mucous membrane. It is noteworthy that other anomalies of pigmentation sometimes accompany the distinctive discoloration. Thus, in Dr. Buzzard's case, "in contrast to the general darkening of the skin there were patches of pure white. . . The margins of the various patches were even more deeply pigmented than the surrounding skin, the appearance suggesting that the pigment had been carried out and heaped up peripherally." Dr. Suckling's patient exhibited both pigmentation and leucoderma. Moles sometimes occur. Renner draws attention to numerous wart-like eminences which he has perceived scattered over the surface. He also states that some cases are attended by atrocious itching. In a contribution to the study of Addison's disease, Dr. Rafaele Caporali[11] mentions, among other points of special interest, in a case under his care, the variable intensity of the bronzing according to the patient's general condition, the pigmentation of the finger nails, and that the regions usually bronzed were but little affected. Dr.

Tyson Smith's case was notable for the abruptness and rapidity with which the "bronzing broke out"—an eruption, indeed,

Though there was pain in the back there was no history of a blow or other injury in the case which I now report.

Addison's disease is not infrequently preceded by a traumatism of the back or abdomen. This may perhaps act as an etiological factor, for the experiments of Schueller have demonstrated that tuberculous disease will locate itself on a site, the vitality of which has been depressed by an injury.

In concluding this study, although I would advise that in all cases of Addison's disease it is proper to make trial of this suprarenal extract, yet as most cases depend upon tuberculosis of the adrenals we can scarcely expect that the extract can cure cases in which the tuberculous process is advanced or active. In earlier stages it may be beneficial by supplying necessary elements to the blood. It has undoubtedly in certain cases achieved very excellent results. The cases in which organotherapy are useful are probably those in which there is a certain amount of atrophy, sclerosis or inflammatory alterations, but in which a portion of the gland or glands are still functionally potent and in which the ingested extract may come to the assistance of disabled but not totally destroyed organs.

DISCUSSION ON PAPERS OF DRS. OSBORNE AND SHOEMAKER.

Dr. A. Bernheim, Philadelphia, mentioned a case he had had under treatment since last February—one of an acute vasomotor ataxia in which he had used suprarenal extract up to 60 grains a day with very good temporary results. The heart sometimes got up to 130, 140, 150, and one time to 160 in one minute, but while taking the extract it came down to below 100, and the tremor subsided, though there was excessive perspiration. He was a young man, 24 years of age, who had to change his shirt twenty to thirty times in the twenty-four hours. He weighed the shirt one day, and found that the difference between the dry and the wet shirts was up to 260 grams respectively. In connection with other treatment the patient has entirely recovered.

Dr. J. C. Melville, Grand Rapids, Mich., said that in his section of the country there are few cases of exophthalmic goiter and but few of cretinism. In a case of cretinism treated by thyroid extract, he observed the most marvelous effect from any therapeutic agent that he has ever seen; there was loss of weight, with clearing of the mental faculties, and return of ordinary intelligence; the progress was gradual but decided and uniform. In exophthalmic goiter, he has used the suprarenal extract with good results, in only one case. In a case of profuse menstruation, with very rapid pulse, the disease had existed for about a year, and many other lines of treatment had been followed without benefit. In regard to dosage, he said that he used 5-gr. doses of the suprarenal extract several times a day, for twenty-one days.

Dr. E. W. Mitchell, Cincinnati, Ohio, said that he had had experience in the treatment of two cases of exophthalmic goiter in which he used the thymus extract with apparently good results. One of these cases was that of a seamstress in whom the exophthalmus was marked. Having tried other remedies without any result, he put her on thymus extract with almost immediate improvement. The tumor, which had been very large, became smaller, the appetite improved, but the tremor was not improved and the pulse-rate was not much changed. He then put her on 25 to 30 grains of hydrobromate of quinin daily, and she made a very good recovery; the exophthalmus, however, is still considerable, but is subsiding under the administration of galvanism. In another woman, in whom quinin was inadmissible on account of ear trouble, marked improvement followed administration of thymus extract.

QUANTITATIVE TESTS FOR PROTEOLYSIS.*

A. L. BENEDICT, A.M., M.D.

Professor of Physiology and Digestive Diseases, Dental Department, University of Buffalo; Editor *American Therapist*.

BUFFALO, N. Y.

It is a remarkable fact that, after ten years' scientific —or, at least, experimental—study of the stomach, none of the methods of chemical examination of gastric contents in common use deals directly with the prime function of this organ. We draw inferences from the rapidity with which the stomach passes its contents into the intestine, often relying on fallacious tests, such as that with salol. We measure as carefully as possible the hydrochloric acid that is present in excess of that functionally active, and assure ourselves that more ferment has been secreted than has been utilized. We note how much or how little the gastric secretion has interfered with the digestion of starches by ptyalin We quantitate and qualitate abnormal accompaniments of digestion. In short, we tax our ingenuity to investigate all the circumstances and accessories of gastric digestion and ignore the direct question as to how well or how poorly the stomach has discharged its prime function of converting albumins into peptone.

The text-book methods of distinguishing one form of proteid from another are not adapted to clinical use. So far as the proteids which may be differentiated in the course of gastric digestion are concerned, no authority—so far as the writer has been able to learn—has attempted a quantitative analysis in the strict sense of the term, although many works on organic chemistry describe the reactions of acid albumin or syntonin, and the subsequent forms which proteid matter assumes during peptic digestion. In these manipulations, however, it is assumed that a comparative abundance of raw material is at hand, a condition which does not exist for the analyst of stomach contents and, explicitly or implicitly, the aim of such manipulations is merely the preparation of a bulk of more or less pure organic substances. The analytic chemist or the clinician, on the other hand, rarely desires a commercial product; he does not insist that analysis shall literally break up a mixed mass into its components, but only that the kind and proportions of these components shall be indicated. It is interesting to note how completely this practical object has been ignored by various writers who have considered the chemistry of gastric digestion, and how utterly lacking are the warnings that would have been indelibly stamped on the memory of any one who had attempted to estimate the proteids of digestion, with the object of obtaining clinical information.

Dr. Arthur Gamgee, in his most interesting and valuable work on "Physiological Chemistry," devotes pages 114-144 of Book II to the consideration of the nature, constitution and reactions of the products of digestion of proteids. In this discussion, he quotes from a considerable number of authorities, yet not a single quantitative statement as to proteid digestion is made, except as to the total dissolving power of pepsin under artificial circumstances. Pages 178-187 (including other pages by reference) are devoted to "Laboratory Work Connected with Gastric Digestion," and nine distinct methods of research are described in detail, but there is not a hint that any one might wish to know what the stomach had actually accomplished in the digestion of proteids.

* Awarded First Gold Medal in Medicine, by the Prize Committee of the American Medical Association, at the Fifty-first Annual Meeting, held at Atlantic City, N. J., June 5-8, 1900.

Ewald's "Diseases of the Stomach, first American edition, 1892, contains an elaborate table of reagents precipitating syntonin, albumose and peptone, but no warning is given of the quantitative difference in "propeptone" (albumoses) according as various reagents are used, nor to the obstacles to the use of mercuric salts and tannic acid, as will be explained later. On page 44, the absence of "propeptone" during the digestion of meat is noted and, on page 45, the subject is brought to a climax as follows: "According to our present knowledge, it is of considerable value to determine and estimate quantitatively, not alone the final but also the intermediate products at any given stage of digestion of albumin." Here the subject is dropped, except for an allusion to the possibility of drawing deductions from various qualitative tests. Nowhere in the clinical chapters is rêference made to this matter, in spite of its "considerable value." The writer confesses that for some years he conscientiously tried to estimate by the bulk of albumin precipitated by boiling, by the ring of albumose above nitric acid and by the amount of peptone and albumose precipitated by a final reagent, how well or how poorly the stomach was performing its function and that he occasionally referred with judicious vagueness to the importance of thus estimating proteid digestion. This period of self-deception passed and the method described in the present paper is due to an effort to obtain, at least, results that are objectively correct though not necessarily so important as to solve all the mysteries of the physiology of the stomach. In the second American translation of Ewald's work, prepared by Manges in 1896, Boas' statement as to the absence of propeptone in the digestion of meat is modified to apply to "that portion of propeptone which is precipitated by rock salt and acetic acid." The importance of noting the amounts of the various products of proteolysis is less emphasized, probably because the impossibility of drawing deductions from qualitative tests had become apparent. In accord with most modern authorities, this second edition mentions ammonium sulphate as the most complete precipitant of albumoses (propeptone) and the opinion is also expressed that very little genuine peptone is formed during gastric digestion. Hemmeter and other authors who have written on the stomach practically ignore the possibilities of quantitative analysis of the proteids of gastric digestion and the few allusions to the subject that may be found in medical periodicals are lacking even in the claim of practical experience in this direction.

Before proceeding to a description of an approximately accurate clinical method of estimating the amounts of proteid present in the stomach contents, in the three easily recognizable stages of digestion, a brief review of the physiologic function of the stomach may not be out of place. Gastric digestion is largely mechanical and, in this respect, deals with all kinds of foods, without reference to chemic classification, but according to their histologic structure, cohesion, solubility, etc., to the end that the entire mass of food may be reduced to a fairly homogeneous pulp. In regard to secretion, the stomach is passive as regards fats, to some degree inhibitive of carbohydrate digestion, active only for proteids and certain closely allied nitrogenous substances, such as hemoglobin, collogen, etc. While fats are essentially foreign bodies in the stomach, starch digestion may, under certain circumstances, be even more complete than proteolysis, though the small reliance placed on either salivary or peptic digestion is evidenced by the fact that the pancreas normally completes the unfinished part of both starch and proteid digestion. According as the meal is small, easily digested and liquid, rather than hearty, mixed and solid, gastric digestion becomes important as compared with pancreatic. Thus, after a meal consisting of a cracker and a cupful of beef-juice, probably nine-tenths of the proteid is peptonized in the stomach; after an ordinary dinner, probably nine-tenths of the work falls to the pancreas. Salivary digestion may be very important if mastication is deliberate and if food is not taken too hot. Under ordinary circumstances it is of very little practical importance. As the stomach empties into the intestine little by little, the first chyme to pass the pylorus is relatively undigested, then the successive outputs become more and more thoroughly freed from proteid by digestion, until, finally, the pylorus relaxes to allow the passage of the practically indigestible residue. This last may be decomposed by bacteria; cellulose giving rise to methane, and tough fibrous animal tissue to ammonia, hydrogen sulphid, etc. Most of the proteid taken by civilized man is coagulated by previous cooking. The only considerable exception arises from eggs—mayonnaise, egg-nog, etc.—and the albumin and caseinogen of milk. For the last, a special ferment exists, secreted both by the stomach and the pancreas, though what functional activity is left for the pancreatic rennet after milk has passed through the stomach, is not apparent. Reasoning on general grounds, one might suppose that the function of rennet was to insure the coagulation of all albumin ingested in the raw state, but simple experiment suffices to disprove this tempting theory. It is questionable just how far raw albumin follows the typical course of proteolysis. Dr. L. Duncan Bulkley's hypothesis that raw milk may be absorbed undigested is not proved, while it has been proved that this is not the usual occurrence. Raw egg-albumin, however, if administered in large amounts, is eliminated as such in the urine, indicating that at least some of it has been absorbed without digestion. Such facts as this—and saccharosuria is an analogous phenomenon on the carbohydrate side—must be borne in mind as qualifications of the general conception that the function of all digestion is to render insoluble substances soluble, so that they may be absorbed.

Peptic digestion requires an acid medium, free acid acting more energetically than acid salts, mineral acid better than organic, hydrochloric acid best of all. This fact should be considered therapeutically as well as physiologically. Under the joint action of pepsin and hydrochloric acid, the changes occurring in coagulated albumin may be divided clinically into three stages: 1, the production of soluble acid albumin or syntonin; 2, the formation of albumoses or propeptone; 3, the formation of pèptone. The exact transformations during proteolysis are so differently stated by different chemists—or by the same chemist in different editions—that no attempt will be made to bring them into harmony with the three demonstrable stages, nor can the moiety theory be applied clinically with our present knowledge.

The method of proteolysis here proposed, depends upon the separation of proteids into the three groups mentioned and on the estimation of the bulk of moist precipitate by the centrifuge. The method is comparatively inexpensive, easy and expeditious and it seems to be sufficiently accurate for clinical purposes. It must not be forgotten that a moist precipitate is very different from an anhydrous product. For example, the most compact moist precipitate of albumin which the writer could obtain by prolonged centrifugalization, contained 75 per cent. of evaporable water. As chemicals are necessary for precipitating albumose and peptone, foreign substances are introduced and, as will be shown later, the bulk of precipitate varies enormously according to the reagent used. Thus, the same technique must be used in successive experiments to allow comparison and, as in most other clinical methods of quantitation, a certain degree of empiricism is unavoidable.

The stomach contents, obtained in the usual way, are cooled under the faucet to prevent further digestion. The most tedious part of all investigations on stomach contents is the primary filtration. After trying various funnels, filter papers, cotton plugs and a small porcelain colander, it was found that there were, for practical purposes, only two alternatives: Either there must be a delay of an hour or several hours while filtration in the ordinary manner was going on, or the chyme could be prepared for rapid filtration by centrifugalization. After twenty to forty turns of the crank the chyme would be reduced to three layers. The uppermost, consisting mainly of esophageal mucus and butter, is removed with a swab of cotton. The middle layer is comparatively clear and readily passes through an ordinary filter. The lowest layer consists of the usual gastric detritus, starch cells, bits of muscle, other food remnants, bacteria, cellular elements, etc. Except as a matter of preliminary study, it is not worth while to investigate the sediment. If a search is to be made for organic proof of cancer, gastritis, ulcer, etc., the sediment from the jejune stomach must be used.

With a few exceptions made necessary by the small amount of stomach contents, all investigations by centrifuge were made on an original volume of ten cubic centimeters of clear filtrate. As will be seen by consulting the various tables, there can usually be obtained enough stomach contents at the height of digestion so that 10 c.c. may be used for the estimation of HCl, 10 c.c. for estimating total acidity (both these amounts are of unfiltered chyme), while there will remain just about enough to afford 10 c.c. of clear filtrate and a few cubic centimeters more for qualitative examination for sugar, lactic acid, starch, etc. The chromometric tests for combined HCl and other kinds of acidity are not very reliable. Gastric contents being almost always acid —always in the cases investigated in this connection—it was necessary only to boil in order to precipitate the syntonin. Control experiments with acetic acid showed that there was no appreciable amount of mucin present to swell the result, provided the process of centrifugalization and filtration was carried out as described. In slow filtration, without previous centrifugalization, a small amount of mucin might filter through, but it would not interfere materially with the tests for proteids. Boiling was done in an ordinary test-tube, on account of the thickness of the centrifuge tube. After cooling, shaking and pouring back into the latter, the albumin was separated by revolving 4000 times—corresponding to 200 turns of the crank of the Bausch & Lomb instrument—as rapidly as possible. Further revolving produced no diminution in the volume of the precipitate. As a matter of safety, the centrifuge was placed on a shelf so that the revolving parts were above the head of the operator. The liquid above the precipitate of impacted proteid could be decanted perfectly clear, filtration being unnecessary.

Ammonium sulphate, 1 gram to the 10 c.c., was added to the decantate from the precipitate of albumin, in order to produce saturation and carry down albumoses. To expedite solution, heat was employed and when the last crystal was dissolved, the tube was cooled by immersion in water. Albumose remains in solution so long as the ammonium sulphate solution is warm, but forms a turbidity when the temperature is reduced. While 4000 revolutions suffice to throw down all syntonin, 8000 were necessary in dealing with albumose. In fact, it was never possible, even by prolonged centrifugalization, to produce an absolutely clear supernatant liquid. However, all but the merest trace of albumose could be precipitated by 8000 revolutions. Nitric acid was used as a control test for albumose, after first removing albumin by boiling and filtering. Even when the white ring of the qualitative test was sharp, no appreciable precipitate could be obtained by centrifugalizing the mixture of chyme and nitric acid, the precipitate appearing to dissolve rapidly in an excess of acid. It is well known that the ring of albumin and albumose produced in Heller's test, dissolves gradually. Other reagents for albumose were not employed in this series of investigations, as none of them precipitates so completely the intermediate products of digestion before true peptone is reached, as does ammonium sulphate.

For peptone, a number of reagents have been proposed and, as usual in successive analysis, they also precipitate albumose and syntonin if the latter have not been previously removed. Tannic acid, the writer found to be objectionable while making some qualitative tests, several years ago. A solution rapidly changes to gallic acid, whose therapeutic value, it will be remembered, is due to its failure to produce precipitates with proteids. The preparation of a fresh solution is somewhat tedious and an attempt to save time by adding the powder to the chyme will only result in further delay. Most important of all, tannin precipitates starch, so that it is unavailable in many cases in which the stomach contents are being examined. While tannin does not precipitate erythrodextrin, small amounts of starch may be concealed by the latter so that it is not safe to use tannin as a reagent for peptone unless the iodin test applied to filtered chyme is free from blue, violet or red coloration. Mercuric chlorid and iodid were found to be extremely unsatisfactory as reagents, dissolving with difficulty and producing insignificant precipitates. On account of the tendency of mercuric salts to form compounds or to become reduced in the presence of all sorts of substances, organic and inorganic, one could not be sure that the small precipitate obtainable was really peptone or a peptonate, unmixed with other substances. Tanret's solution of mercuric iodid is stable and convenient, but of doubtful reliability for the purpose under discussion. On the whole, phosphomolybdic acid has proved the most satisfactory precipitant of peptone that the writer has employed, producing a very bulky precipitate, usually between a tenth and a fifth of the total contents of the tube. To avoid adding too much reagent, it is best to begin with about .5 c.c.—Merck's guaranteed solution was employed—and revolve 500 times. On adding another drop, it can be seen whether further precipitation occurs or whether there is already present sufficient of the reagent. Four thousand revolutions suffice to form a firm precipitate, not diminished by further centrifugalization, though it is probable that a more powerful instrument would have reduced the bulk still further.

In some instances, the decantate, after throwing down albumose, was divided into two equal parts, one being tested with phosphomolybdic acid, the other with Tanret's solution or tannin. No concordance could be established between the result by phosphomolybdic acid and that by Tanret's reagent. The precipitate of all forms of proteid by tannin was never equal in bulk to that of peptone alone, by phosphomolybdic acid. This fact aroused the suspicion that the precipitate by the latter might include something else than peptone, for instance the result of a reaction with ammonium sulphate or with some of the numerous inorganic or organic substances contained in chyme. Control tests, however, showed that no precipitate occurred with ammonium sulphate nor with substances present in the stomach contents after precipitation of all proteids by tannin. With normal urine, which contains most of the inorganic radicles and examples of the extractives that might be present in stomach contents, only a blue color was produced, never a precipitate. In several cases of albumosuria—formerly called peptonuria—phosphomolybdic acid precipitated nothing after the albumoses had been removed with ammonium sulphate, though, as was to be expected, heat and nitric acid still left proteids precipitable with phosphomolybdic acid. Entirely aside from these crude experiments, there is good chemic authority that the only substances liable to cause a confusion in using phosphomolybdic acid as a test for peptone in chyme, are alkaloids. It is impossible that alkaloids could be present in the stomach in sufficient quantity during life to interfere with the test for peptone.

The writer acknowledges, with thanks, information as to chemic reactions furnished by Herbert M. Hill, Ph.D., of Buffalo; J. Bergen Ogden, M.D., of Boston; Henry Leffmann, M.D., of Philadelphia, and Albert J. Leeds, M.D., of New York. The writer also acknowledges with the most hearty thanks, the sacrifice of time and convenience of the following-named graduates of the Medical Department of the University, of the class of 1898. For an overworked medical student to devote the only half-holiday of the week to laboratory study, not only on an empty stomach, but on a stomach which had itself been the object of experimentation, evinces a degree of enthusiasm not often found this side of the Atlantic. The takers of the test meals mentioned in Table 1 were: Drs. Richard J. Gould, Gifford Truesdell, Edith W. Stewart and H. M. Smith.

(To be continued.)

Experimental Spinal Cocainization.—The *Cbl. f. Chir.* of February 9, mentions the experimental work of a Russian confrère Golebski, who experimented on forty-six dogs and numbers of frogs, inducing analgesia by spinal cocainization. The results coincide in the main with those observed on man. Frogs first lost their sensibility to the effect of acids on the skin, and retained longest the sensation of simple contact. Electric excitability survived sensibility to pain in dogs. Ataxia of the hind legs always accompanied the analgesia. The temperature rose with large doses of cocain, but this could be prevented by injecting antipyrin with the cocain. He was able to ward off strychnin, picrotoxin and aconitin convulsions by means of this spinal cocainization, and even succeeded in making a stomach fistula on dogs that were not fastened in any way. The *Sem. Méd.* of February 20 states that Carini's experiments on dogs injected with as much as 20 cg. to 1 gm. of cocain, demonstrated changes in the nerve cells afterward, similar to those observed in the spinal cord after temporary compression of the abdominal aorta. These changes are merely brief, transient processes of reaction on the part of the cells, with complete restitution.

ANASTOMOSIS OF THE URETERS WITH THE INTESTINE.

A HISTORICAL AND EXPERIMENTAL RESEARCH.*

REUBEN PETERSON, M.D.
Professor of Gynecology Post-Graduate Medical School; Assistant Clinical Professor of Gynecology, Rush Medical College; President of the Chicago Gynecological Society.
CHICAGO.

(Concluded from p. 738.)

3. URETERO-TRIGONO-INTESTINAL ANASTOMOSIS.

Of the twenty-one dogs operated on, twelve died from peritonitis due to sloughing of the bladder-flap. Four died of peritonitis from other causes, and there were five operative recoveries.

This series of experiments was undertaken for the purpose of studying the changes resulting from the union of the intact vesical ureteral orifices with the intestinal tract. A supplementary object was to simplify Maydl's operation, which seemed unnecessarily complicated. In this series also the operative results were bad, but an entirely new field was being approached, and one slip in technique was responsible for the loss of twelve dogs. I have been unable to find in literature a record of a single dog saved after transplantation into the bowel of the trigonum with its ureteral orifices. Kalabin attempted the operation on five dogs, and Matas two, but they all died of peritonitis. In the first experiments care was taken to preserve the ureteral arteries, which could be seen running close to the ureter and approaching the bladder-wall close to the ureteral orifices. It was assumed that the trigonum, as well as the ureters, was supplied by these arteries. Accordingly, in the first twelve experiments the vesical arteries were tied before cutting out a rectangular flap containing the ureteral orifices. This was done in order to control hemorrhage, which was quite profuse when the bladder was cut across without previous ligation of the artery.

The dogs lived for a number of days, finally succumbing to peritonitis with sloughing of the transplanted flap. The specimen from the twelfth dog was subjected to microscopic examination and the flap demonstrated to be necrotic, although macroscopically it appeared in good condition, and there was no leakage of urine into the abdominal cavity.

The blood supply of the trigonum in the dog was then studied by plaster injections and dissection. It was found that the main blood supply to the trigonum was from the vesical arteries, each of which is given off from the internal iliac artery. These arteries anastomosed with the ureteral arteries, but not freely. This explained why, in the previous experiments, the color of the flap was markedly changed only in those dogs that lived quite a number of days. There was some blood going to the flap from the ureteral arteries, but not enough to nourish it. In the next nine experiments the vesical arteries were preserved, with five recoveries from the operation. Two of these dogs died respectively in eight and twelve days, from abscesses in the abdominal wound, but they proved to be just as valuable for studying the changes following the rectal implantation of the trigonum.

The four deaths were from peritonitis resulting from attempts to unite the vesical flap to the bowel by a simple continuous suture. The result was leakage, peritonitis and death. The operation is difficult to perform on the dog, because of the absence of a sigmoid flexure and the ficulty encountered in pulling down the gut to meet flap. The flap cannot be drawn up beyond a certain nt on account of the necessity of preserving the vesical arteries which are given off from the internal iliac low down.

---

* Read before the American Gynecological Society, Washington, D. C., May 1, 1900.

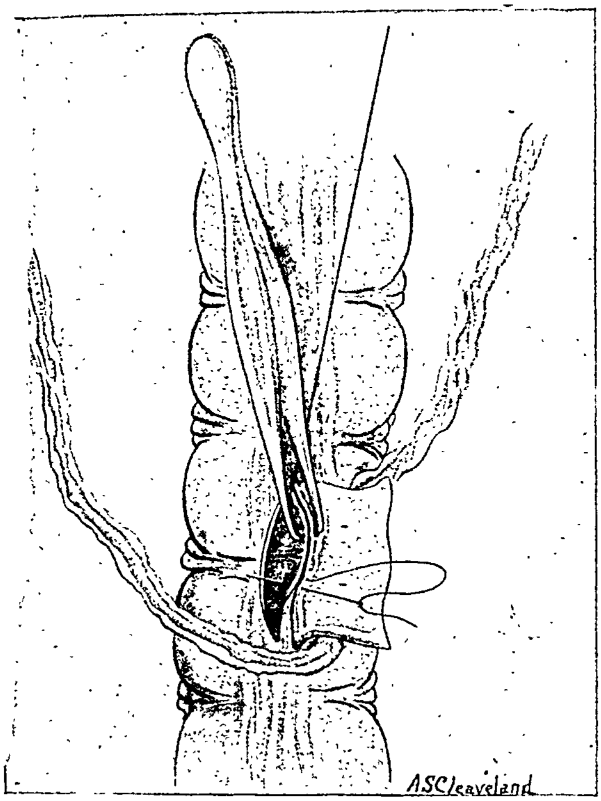

Fig. 16.—Showing incision through intestinal serosa and mus-.laris. Long margin of vesical flap united to one side of bowel .cision by right-angled through-and-through continuous suture.

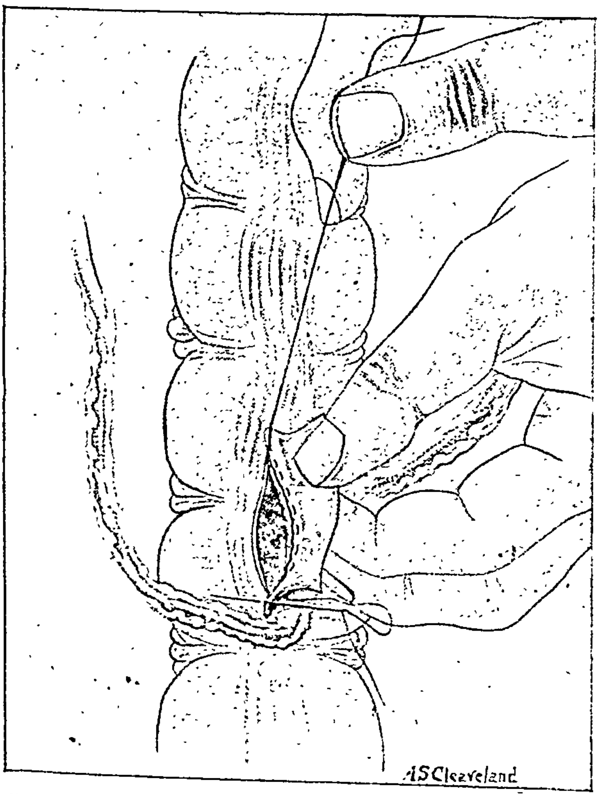

Fig. 17.—Showing method of turning angle and the inversion of the peritoneal surface of flap.

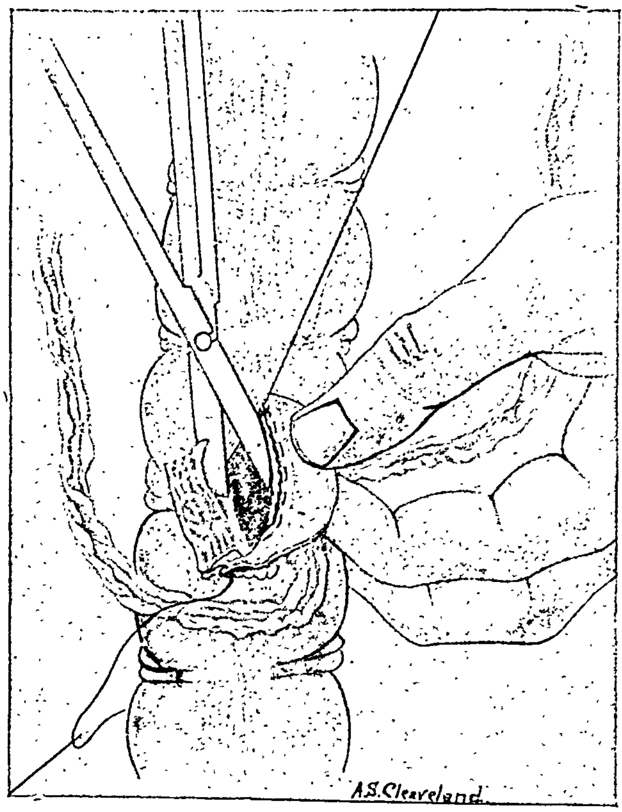

Fig. 18.—Showing the removal of the mucosa by the scissors Up to this time the bowel has remained closed.

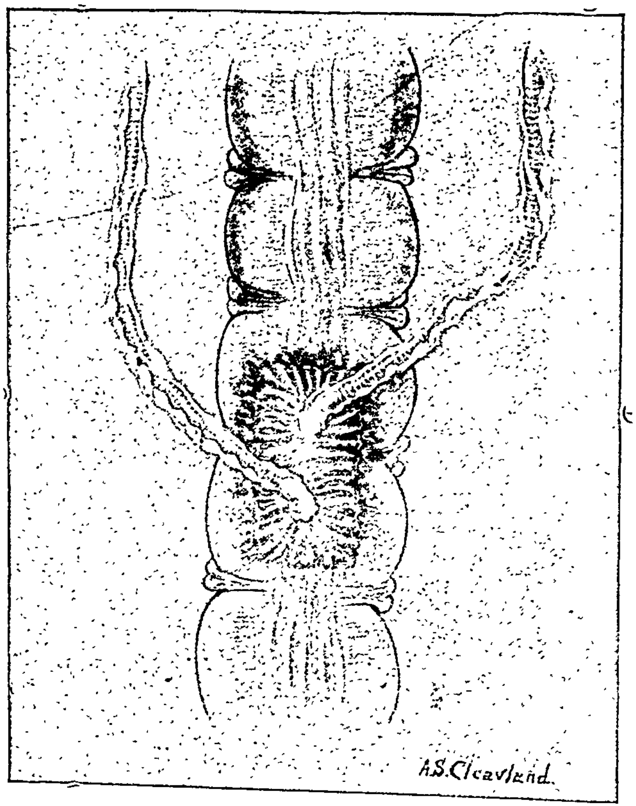

Fig. 19.—Suture of flap completed. Peritoneal edges still further rolled in by a series of Lembert sutures.

Operative Technique Finally Adopted. After opening the abdomen the bladder is brought into the incision and the urine evacuated by careful pressure. The urethra is ligated low down; in the male as near the prostate as possible, by passing the ligature inside the vesical arteries. The urethra is clamped just above the ligature and severed. The abdomen is protected by sponges and the clamp removed, the residual urine being expressed in a sponge. The urethra and bladder are now split with the scissors between the vesical arteries to the fundus of the bladder. A rectangular flap is now formed by cutting the bladder across, care being taken to leave a half-inch border around the ureteral orifices. (Fig. 15.) The ureters are not loosened from their peritoneal coats, as shown in the illustration. In fact, they are hardly to be seen, and are only avoided in the subsequent stitching by placing bougies in the ureteral orifices. A fold of the descending colon is now seized and drawn down and incised longitudinally at such a point as will be most convenient for meeting the bladder-flap. The incision should be just a trifle less in length than that of the flap, and should be made down to the mucosa. The flap should now be placed against one side of the incision with serosa against serosa and the two borders united with a through-and-through right-angled stitch. (Fig. 16.) This stitch includes on the bowel side only serosa and muscularis, but all the layers on the flap side. When the lower end of the incision is reached the same stitch is employed, only, to save time, a single bite is made on the bowel side. The mucosa is pushed toward the center of the vesical flap, so that part muscularis and part serosa are brought in contact with the bowel serosa. A perfect inversion of the edge is accomplished by means of the suture. (Fig. 17.) When one-third of the distance has been closed on the opposite side from which the stitch was started, as much of the bowel mucosa is removed by the scissors as may be deemed necessary to allow the ureteral orifices to fall within the incision. (Fig. 18.) After the low ends of the suture have been tied, another continuous suture, or a series of Lembert's sutures is applied in order to guard against any possible leakage. (Fig. 19.)

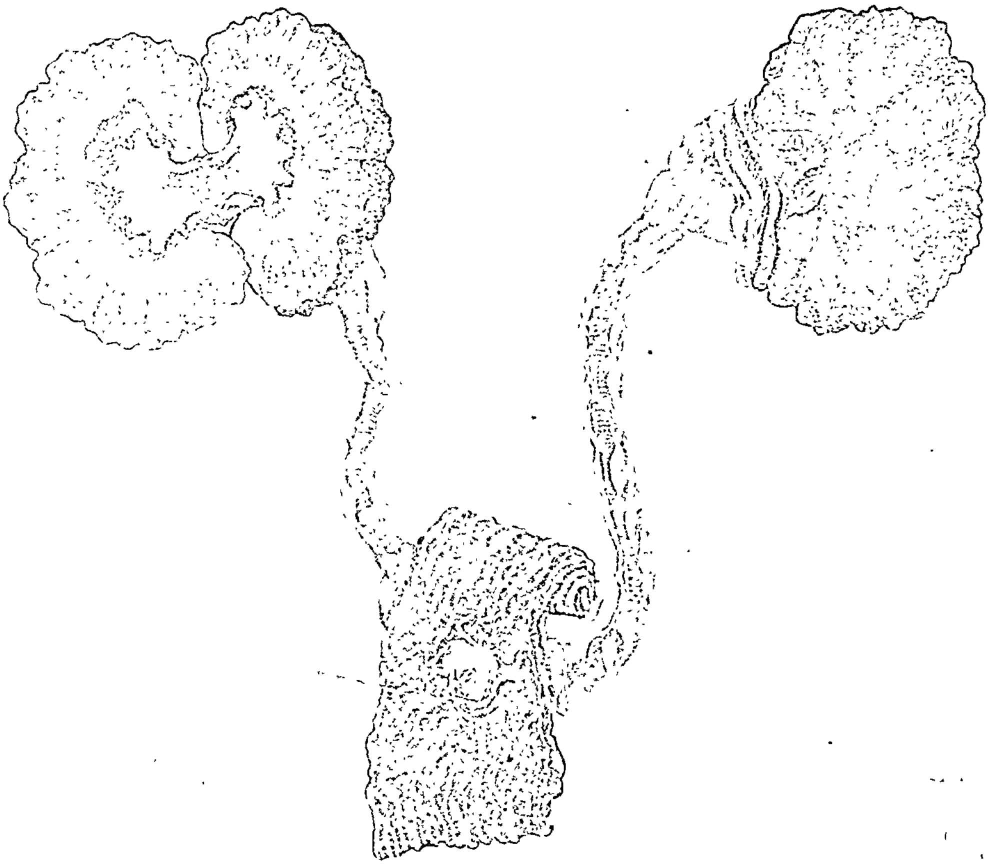

Fig. 20.—Kidneys, ureters and section of rectum of a dog killed thirteen months after bilateral rectal anastomosis.

Experiment 67. Dog IX. (Dog XI. Pathological Reports.) Large yellow male. Operated on January 18, 1900. One-half the trigonum, with left ureteral orifice, was anastomosed with bowel according to method described above, except the bowel mucosa was simply incised, and no portion removed. The bladder was sewed up with two rows of silk sutures. The dog made an uninterrupted recovery, and was killed March 24, 1900, sixty-five days after the operation.

Pathologist's Report. Atrophied kidney, due to occluded ureter. Capsule adherent, thickened, and opaque; kidney anemic, grayish-brown surface, slightly nodular. Left ureter twice the size the right and non-patent.

Bacteriology. Smears from liver, kidney, spleen, and heart negative.

In this case the incised mucosa had united, and after occluding the ureteral orifice had produced an atrophic kidney. This fault in technique was remedied after this case.

Experiment 66. Dog X. (Dog VI., Pathological Reports.) Small, yellow dog. Operation January 18, 1900. Right ureterrectal anastomosis by old method. Left trigonum with its ureteral orifice anastomosed with rectum. Died from sloughing of abdominal wound, giving rise to general peritonitis thirteen days after the operation.

Pathologist's Report. Left kidney: Capsule adherent; cortex and medullary portion equally thick; pelvis smooth. Right kidney: Opaque; capsule adherent; cortex shows hyperemia and yellow millet-seed sized areas—former surrounding latter. Swollen and congested cortex and purulent rays from pelvis to cortex; pelvis dilated; papillæ necrotic, pyelonephritis.

Bacteriology. Left kidney negative; right kidney contains colon bacilli.

Histopathology. Left kidney fairly normal, shows only some hyperemia, and slight cloudy swelling of lining epithelium of convoluted tubules; no bacilli found. Right kidney shows acute suppurative interstitial nephritis, with colon bacilli present.

Experiment 68. Dog XI. (Dog XII., Pathological Reports.) Small, yellow dog. Operation January 24, 1900; killed March 24, 1900. Same technique as above, except mucosa was denuded slightly about edge of the flap; good recovery.

Pathologist's Report. Very ill with mange when killed, two months after operation. Right and left kidney capsules non-adherent; normal; no pyelonephritis. Ureters normal; spleen large and soft; liver fatty. Fibrinous thrombi in left ventricle.

Bacteriology. All smears and cultures from the above organs were negative.

Histopathology. Kidneys show slight parenchymatous changes, due probably to mange. Thrombus in left heart; infected spleen and fatty liver. No pyelonephritis nor the sequelæ of a possible preceding pyelonephritis were found.

PLATE I.

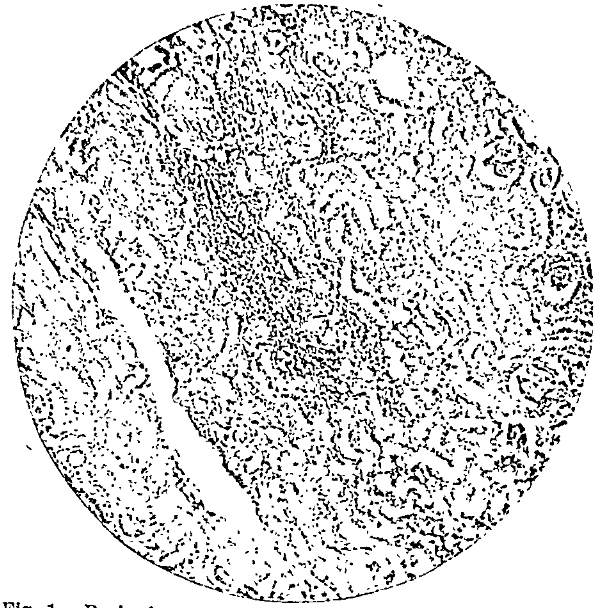

Fig. 1.—Beginning ascending infection after implantation of ureters in rectum. Leucocytic interstitial infiltration, surrounded by convoluted tubules, with beginning cloudy swelling.

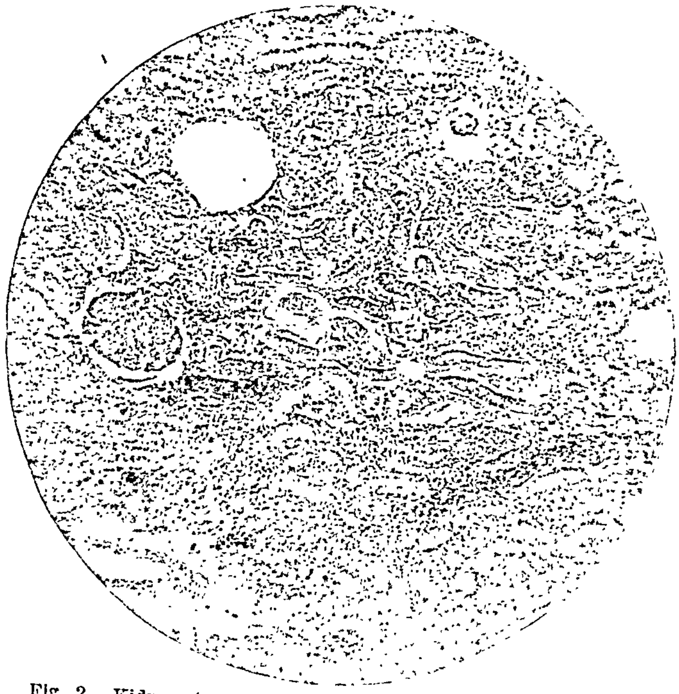

Fig. 2.—Kidney (ureters in rectum) showing invasion by the bacilli coli at an early stage of ascending infection. The dark masses in uriniferous tubules consist entirely of coli bacilli. Some contain casts which are sown with coli bacilli.

Experiment 69. Dog XII., (Dog VII., Pathological Reports.) Brown spaniel bitch. Operation January 25, 1900; died March 10th, forty-four days after operation. Ordinary technique was employed, except in trimming the vesical flap too much was removed and ureteral orifices were laid bare. Flap was sewed transversely across the bowel.

Pathologist's Report. Both kidneys show opaque adherent capsules and pyelonephritis. Both ureters patent; hydro-ureter right side; liver and spleen normal. Both kidneys show coli.

Histopathology. Necrotic papillæ. Polymorphonuclear leucocytes in tubules in great numbers, with small-cell infiltration in ureteral tissue. Some necrosis and much cloudy swelling and fatty degeneration of epithelial cells of convoluted tubules.

Experiment 74. Dog XIII. Brown female dog. Operation March 30, 1900. Left half of trigonum with mucosa removed, and right half with mucosa intact, anastomosed with rectum. Dog died in eight days from abscess of abdominal wall.

Pathologist's Report. Left kidney shows pyelonephritis; ureter normal, pyelitis, with slightly adherent capsule. Right kidney has a very adherent capsule. Organ slightly hyperemic; no pyelonephritis. Heart: yellow fibrinous thrombi in both ventricles.

Bacteriology. Smears of left kidney, cortex, and pelvis show pure coli. In the pelvis also a few tetanus bacilli. Left kidney: Cortex coli. Right kidney: Cortex contains a few very small, thin diplococci.

PLATE II.

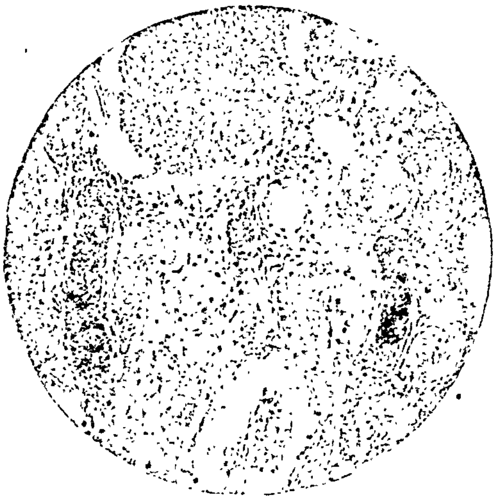

Fig. 3.—Kidney (ureters in rectum) showing invasion by the bacilli coli at an early stage of ascending infection. The dark masses in uriniferous tubules consist entirely of coli bacilli. Some contain casts which are sown with coli bacilli.

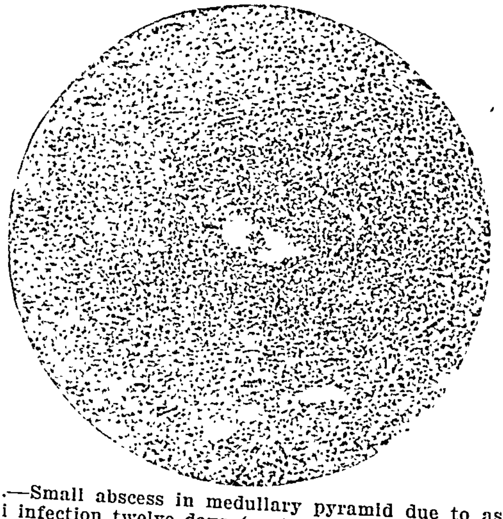

Fig. 4.—Small abscess in medullary pyramid due to ascending coli bacilli infection twelve days (ureters in rectum).

Summarizing the results of these five experiments, we find that in one case the ureter was occluded from faulty technique, with formation of an atrophic kidney. Of the four remaining cases, one had a non-infected kidney, where the trigonum was implanted intact; pyelonephritis on the other side, where a uretero-rectal anastomosis had been made. One died in forty-four days from active pyelonephritis, where the mucosa over the ureteral orifices had been accidentally removed. One lived two months without signs of infection in the kidneys. One had pyelonephritis after eight days, where the mucosa was removed from the ureteral orifice, and no signs of infection in the other kidney, where the trigonum was implanted intact.

The experiments fully confirmed the observations of others, that in the dog the rectum serves as an admirable substitute for the bladder. In most instances, directly after the operation, some rectal tenesmus existed, but this soon passed away, and the animal had perfect sphincteric control, and passed urine mixed with feces at regular intervals.

It seems questionable whether uretero-intestinal implantation without a vesical flap will ever be accomplished without a certain amount of resulting stenosis of the ureteral orifice. This stenosis may not be sufficient to entirely obstruct the urinary stream, but it will be enough to impede it somewhat and give rise to the dilatation of the ureter in varying degrees. Without having actually accomplished an anastomosis with the Boari or Chalot button, it would seem to me that the uretero-rectal union by these means would be open to the same dangers of stenosis as a union secured by the method detailed above. Boari, in the article describing his button, does not appear very sure that stenosis will not result from its use, for he speaks of a modification of the instrument whereby stenosis will be rendered impossible. The second series of experiments has proved that ascending renal infection is not prevented by an unobstructed flow of urine, since the case of lateral anastomosis without stricture was quickly followed by a violent infection.

PLATE III.

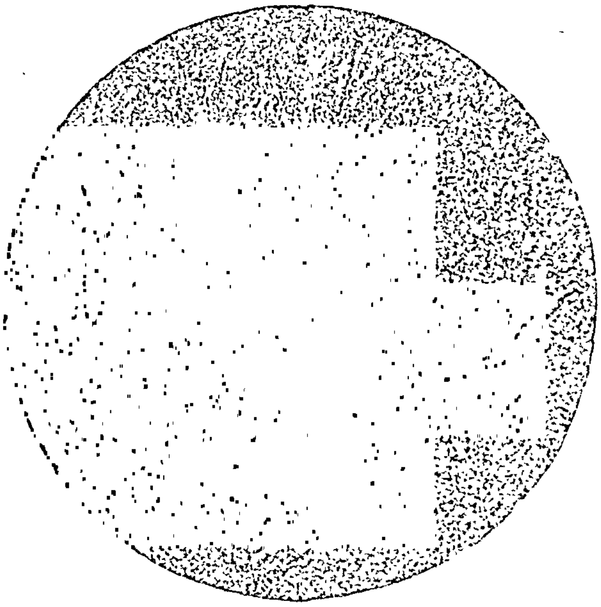

Fig. 5.—A later stage of ascending coli infection. Specimen from medullary pyramid. A central necrotic area with few bacilli, surrounded by a dense zone of leucocytic infiltration.

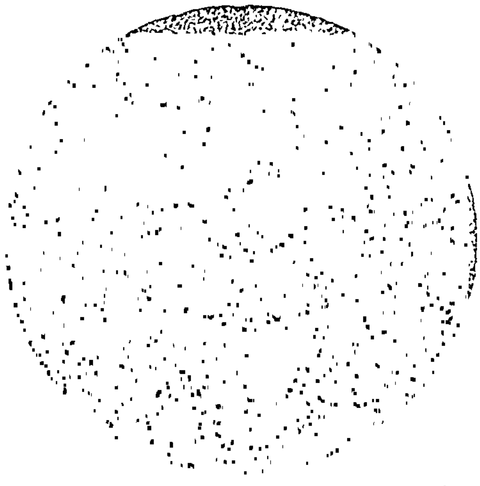

Fig. 6.—Ureter in rectum. Interstitial suppurative nephritis due to ascending coli infection. The leucocytic infiltration is so extensive that only little of the kidney structure can be seen. (Cortical portion.)

PLATE IV.

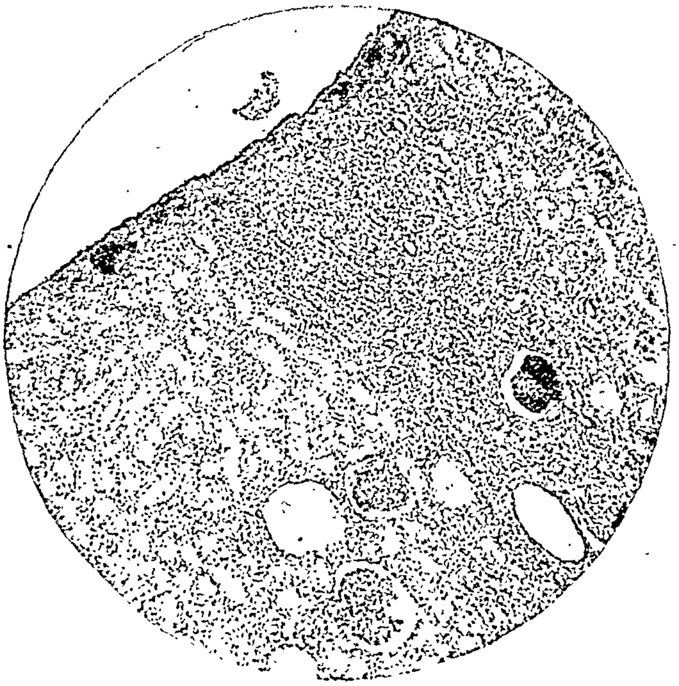

Fig. 7.—Thirteen-months dog. Granular kidneys. The dog had a pyelonephritis, became immune to coli bacilli, and the many small abscesses spread over the cortex of both kidneys resulted in retracting maturing scar tissue. The elevated portions surrounding these show fairly normal parenchyma. The retracted portions consist of matured new connective tissue with atrophic glomeruli, thickened capsules, dilated and desquamated tubules.

PLATE V.

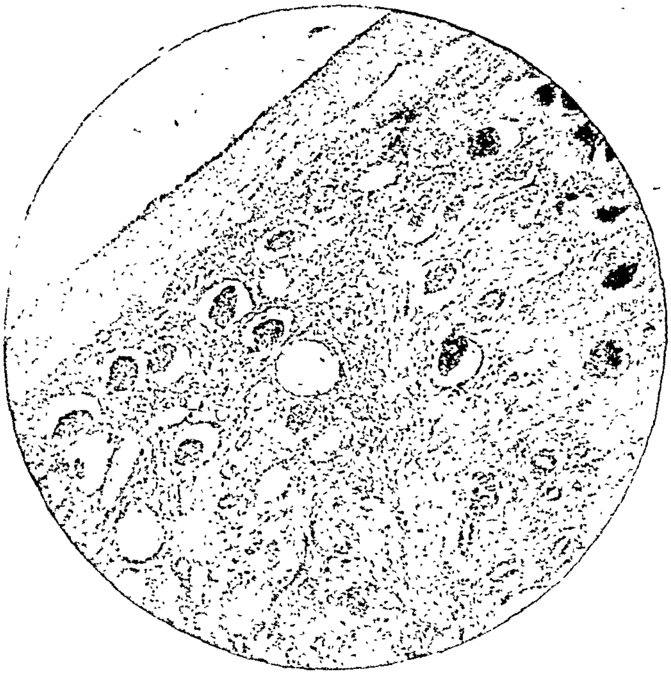

Fig. 8.—Results of healed pyelonephritis ten months after implantation of ureters into rectum. A cirrhotic contracted kidney. Only scar tissue with atrophic glomeruli, dilated desquamated tubules.

Tuffier claimed that if the ureter were cut off close to the bladder and implanted into the rectum, its musculature by forcing along the urine would keep the ureter clean and free from infection. In order to test the truth of this statement I intentionally severed the ureter as near the bladder as possible in Experiment 66, Dog X., yet pyelonephritis resulted thirteen days after the operation.

My experiments show beyond question that renal infection is not so rapid nor so severe when the vesicoureteral orifice is preserved. It is not claimed that infection will not occur after the operation, but that at least one case of uretero-rectal anastomosis where the orifices were retained intact did not show infection after two months. The animal surviving this length of time had to be killed for the purpose of this article. No amount of speculation will settle the question of infection later than two months after the operation. This must be determined by further experimental work.

PLATE VI.

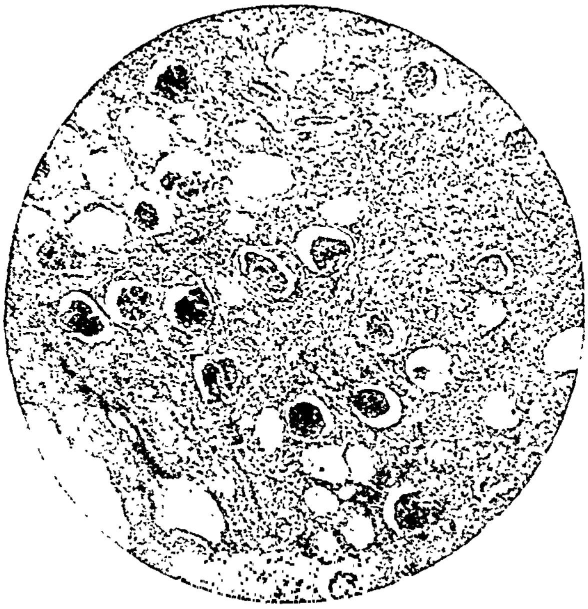

Fig. 9.—Results of healed pyelonephritis ten months after implantation of ureters into rectum. A cirrhotic contracted kidney. Only scar tissue with atrophic glomeruli, dilated desquamated tubules.

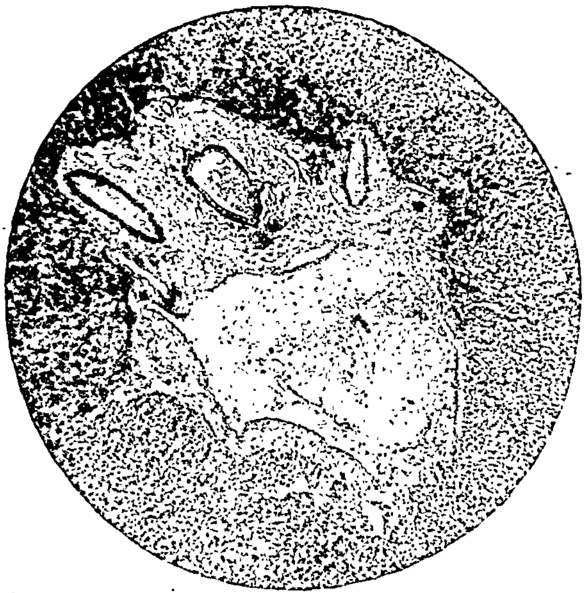

Fig. 10.—Thrombosis of portal vein. Liver. (Passive hyperemia. Atrophic areas.)

Why does not infection occur as readily when the ureteral orifice is implanted intact? Theoretically, it has been argued that infection has been prevented by the oblique course of the ureter through the implanted vesical flap, or that germs were prevented from ascending by the sphincteric or valve-like apparatus about the ureteral orifice.

That the oblique course of the ureter through the bladder-wall does not prevent an ascending renal infection has been proved conclusively by certain of my experiments. Whenever the mucosa was removed from the ureteral orifice infection resulted, although the obliquity was unchanged by this procedure. The oblique course of the ureter in the bladder-wall serves to effectually close the ureter when the bladder is distended and prevents any ureteral reflux. So perfect is this closure that a bladder can be distended with air or

PLATE VII.

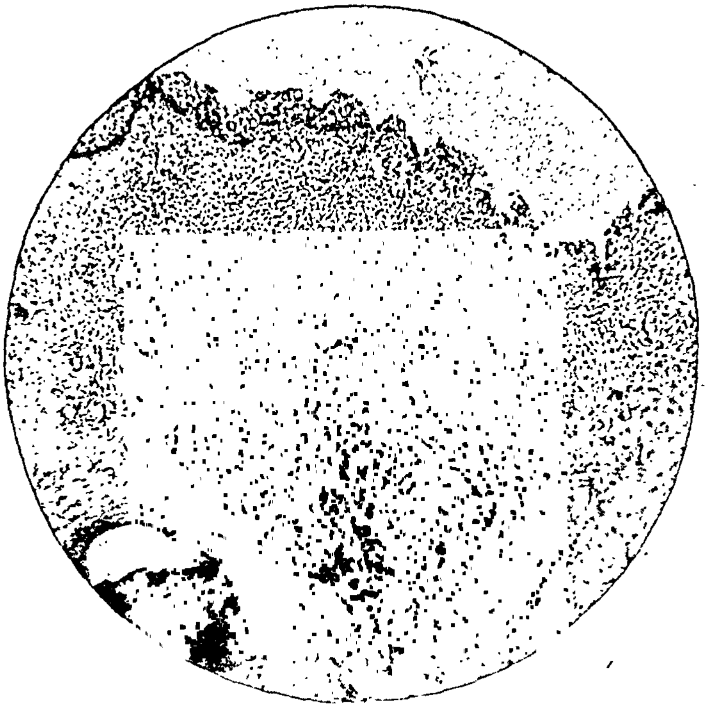

Fig. 11.—Bladder of dog with both ureters implanted in rectum. Ascending infection from urethra, causing cystitis. Much small cell infiltration of mucosa with desquamation of covering epithelium.

PLATE VIII.

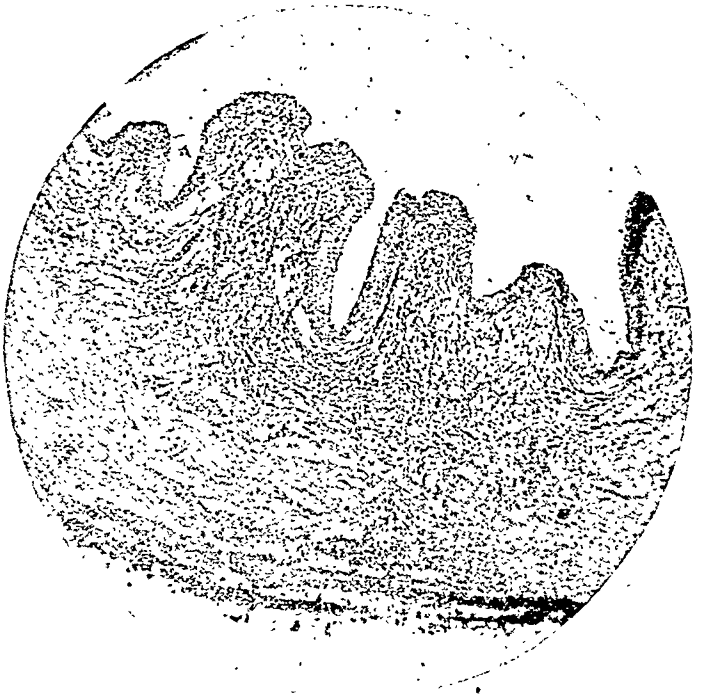

Fig. 12.—Ureter (implanted in rectum). The kidney showed pyelonephritis. The ureter looks comparatively healthy in strong contrast to the necrotic papillæ of same kidney.

water through the urethral orifice without any escaping through the ureters. This mechanical closure of the ureteral orifices does not take place after the transplantation of the vesical flap, since the rectum is not a closed cavity and the same forces are not called into play.

In order to determine definitely the relations of the ureter to the different vesical muscle layers and to ascertain the existence or non-existence of a sphincter or valve at the ureteral orifice, I caused to be made a set of serial sections through that part of the dog's bladder-wall through which the ureter passes.

The results of these microscopic examinations may be stated as follows:

1. The sections do not show a mucosal valve guarding the entrance to the ureter.
2. The circular muscle layer of the ureter is not especially prominent.
3. The bladder muscle fibers in themselves do not act as a sphincter, nor is there any sphincteric arrangement about the vesical ureteral orifice.
4. Sections of the ureter within the bladder-wall show a flat slit-like opening.

Thus it will be seen that all theories based upon the supposed action of a valve or sphincter apparatus guarding the ureteral orifice, whereby ascending infection is prevented, must be set aside from the lack of anatomical evidence. From this it will naturally follow that all attempts to prevent infection by imitating in the bowel-wall the normal course of the ureter will prove futile, as the post-mortem findings of Martin's cases have clearly shown. Beck's theory that in his case infection was prevented by inserting a portion of the ureter within the bowel has been shown to be incorrect by numerous experiments. The portion of the ureter lying within the bowel soon completely sloughs away, and, far from preventing infection, is one of the chief factors in its production.

What can be said of Fowler's mucous valve formation for preventing infection? As far as the case is concerned the patient is still living and apparently well after three and a half years, yet experimental work would lead us to conclude that the kidneys have been infected, but that the infection has been overcome with resulting contracted kidneys. In order to ascertain the value of such valve formation as Fowler recommends, I performed the operation upon a dog, March 31, 1900, carrying out his technique strictly, except that only one ureter was implanted. The dog recovered and was killed at the end of twenty-seven days. The kidney corresponding to the implanted ureter was decidedly smaller than the other and showed evidence of ascending infection. No bacteriologic or microscopic report on the specimen has yet been made. The ureter was slightly dilated. There was not only no vestige of the ureter which had projected into the bowel cavity, but the mucous flap itself had disappared, and the ureter, fairly patent, opened through a small slit in the mucosa.

The most plausible theory regarding infection or non-infection would seem to be that any traumatism to the ureter, whether in the form of its complete section or injury to its orifice by removal of the vesical mucosa, sets up an inflammatory action about the ureteral orifice which diminishes its power of resistance and allows of ascending infection. Whatever method of intestinal anastomosis of the severed ureter be employed, inflammatory changes are bound to be present, and infection will follow. Whereas, when the ureteral orifices are implanted together with the bladder flap, any operative traumatism is exerted upon the latter and the unaffected ureteral orifices are able to prevent the entrance of bacteria.

GENERAL CONCLUSIONS.

1. The primary mortality of uretero-intestinal anastomosis, both in experimental work on animals and in man, is exceedingly high.
2. The best technique is that requiring the least amount of suturing of the ureters themselves.
3. All efforts to prevent ascending renal infection in animals or in man where the ureter has been implanted without its vesical orifice have proved futile.
4. It is impossible to determine in advance the extent of the infection which will result from uretero-intestinal anastomosis. The patient may die in a few days of a pyemia or in a short time of pyelonephritis, or in rare cases may recover from the infection, with resulting contracted kidneys.
5. Hence the operation is unjustifiable, either for the purpose of making the patient more comfortable, as in exstrophy of the bladder, vesico-vaginal or uretero-vaginal fistula, or for malignant disease of the bladder.
6. The results of uretero-intestinal anastomosis through the formation of vesico-rectal fistulæ have not been favorable up to the present time.
7. The success of Frank's experimental work in vesico-rectal anastomosis justifies the expectation that the future results of this operation will be more satisfactory.
8. The primary mortality of utero-trigono-intestinal anastomosis is low for an operation of this magnitude.
9. While it can not be denied that ascending renal infection may occur after this operation, the infection, as a rule, is of such a type that the chances of the individual's overcoming it are good.
10. Hence the operation of implanting the vesical flap with its ureteral orifices into the intestine is a justifiable surgical procedure.
11. There is no valve guarding the vesico-ureteral orifice; nor does the circular muscle layer of the ureter nor do the bladder muscles themselves act as a sphincter.
12. It has been abundantly demonstrated by experimental and clinical work, that the rectum tolerates the presence of urine and acts as a good substitute for the bladder, and that good control over the anal sphincter will be maintained.

Quinin as an Oxytoxic.—McGee (*Bul. of Cleveland General Hospital*, ii, No. 4) believes quinin possesses evident power as an oxytoxic. He has "given it in almost a routine manner for years, in cases of uterine *inertia*." He finds that while it will not initiate labor pains in pregnancy, in the second stage of labor, when there is an obstacle to delivery or contractions are deficient in force, it frequently increases their power and so hastens delivery. He *ascribes* its effects to a general tonic action and increase of nervous energy, rather than to any specific power, such as ergot has, and he says it is devoid of the dangers of the latter. He gives 5 grs. every twenty minutes or so till about 20 grs. are taken; it is best prescribed in solution; added to a small quantity of brandy or whisky diluted with hot water and well sweetened, he finds it is rarely refused.

DIPHTHERIA.

There are few chapters in the history of medicine more interesting and more complete than that of the evolution of our knowledge of diphtheria; and the stages by which this advance has been made have been the result not of accident nor of chance, but of systematic and industrious investigation of the best scientific character, interpreted by a high order of intelligence. Ulcerous and membranous anginas have long been recognized and described, but the first severe and widespread epidemics of recent times are recorded as having occurred in the seventeenth and eighteenth centuries. During the early part of the nineteenth century France was assailed by numerous disastrous epidemics, which played sad havoc, even among the royalty, so that Napoleon I., in 1807, offered a prize for the best essay on croup. Great confusion regarding this disease existed until Bretonneau published his famous work in 1826.

Escherich,[1] in an interesting communication, discusses the changes that have taken place in the clinical conception of the term diphtheria in the course of the past century, especially as a result of bacteriologic investigation, as well as certain related topics. Bretonneau not only verified previous descriptions of the disease, its dissemination by contagion, the appearance of the deposit, the stenotic and toxic characteristics of its course, and the varying localizations and sequels; but he further established the pathologic-anatomic basis of these manifestations. From epidemiologic and postmortem considerations, he divined the specificity of the disease, and suggested the existence of a living contagium. Clinically he recognized the identity of croup and diphtheria, attaching the greater importance, however, to the effects of laryngeal obstruction, to the neglect of the symptoms of intoxication. He appreciated the utility of tracheotomy and practiced it successfully. Trousseau, a friend and pupil of Bretonneau, laid great stress on the toxic manifestations, and considered the disease a general one with local lesions.

Confusion arose from the application of the terms croupous and diphtheritic to fibrinous or membranous deposits upon mucous membranes in general, and the inclusion of all superficial necrotic lesions of wounds and the various mucous membranes, especially the tonsils in cases of scarlet fever, under true diphtheria. The final and decisive discrimination was, however, not reached until the discovery by Klebs, in 1883, and the cultivation by Lœffler, in 1884, of the diphtheria bacillus. This was followed by the isolation of the toxin generated by the bacillus, and this, in turn, by the development of immunizing methods in animals, and finally, in 1894, by the preparation of the antitoxin—the entire series of events constituting one of the most brilliant and most beneficent discoveries in the history of medicine. The severity and the course of the disease were at first attributed directly to the virulence and the number of the active bacilli, but evidence was soon discovered showing that those conditions are due in no small measure to the state of the body, and that this is probably dependent on the presence or absence of protective substances. An additional factor is to be found in the existence of mixed infection, in part with streptococci.

The most important feature of the advance in our knowledge of diphtheria consists in the treatment and its results. Debilitating and antiphlogistic means were superseded by general supporting and vigorous local treatment with astringents, caustics and antiseptics, while tracheotomy and later intubation came into practice for the relief of laryngeal stenosis. The use of steam for inhalation proved a useful adjunct. The results of treatment were, however, unreliable and unsatisfactory until the discovery of the antitoxin in 1894. Since then the mortality has been cut in half, the gain being most marked the earlier the specific remedy is employed and the dose chosen sufficiently large. The necessity for surgical intervention has also become less, and, when it has been required, the results have been better than heretofore, while complications and sequelæ are more uncommon. The prophylactic value of the antitoxin is somewhat impaired by the circumstance that the immunity conferred is of brief and uncertain duration, but evidence exists showing that it may nevertheless be successfully directed to the breaking up of epidemics in hospitals and other institutions, and in private dwellings. In the treatment, it can not be too forcibly emphasized that the dose to be employed is the largest that the severity of the case indicates, and its repetition will be influenced by the same criterion. An important point to be appreciated is the necessity for employing as concentrated solutions as possible, as such secondary effects as have been observed after injection of the antitoxin are due not to the active principles but to the serum in which they are dissolved. The two possible contraindications to the use of the antitoxin consist in the presence of nephritis and the so-called lymphatic constitution.

THE STEREOGNOSTIC SENSE.

In 1883 Charles Bell originated the term "muscular sense," and attributed the conception of place and position to a particular form of sensation located in the muscles. This sense was thought to be a primitive one, due directly to the "organic activity of the muscular contractions." According to Puchelt, it was assigned the rôle in the perception of form and was called, at the time, the stereognostic sense.

---

[1] Berliner klin. Woch., 1900, No. 2, p. 33.

It is to-day generally believed that the stereognostic sense is dependent on the use of the tactile and muscular senses. To examine the stereognostic sense of a patient methodically, one has only to use geometrical bodies, such as balls, half-spheres, octahedrons, etc., preferably made of wood, measuring from 3 to 6 cm. in diameter, and ask the patient to describe them, as they are placed in his hands.

As the result of a somewhat exhaustive study, Sailer[1] has concluded that the stereognostic sense is due to a complex sensory perception, the impulses of which are probably received in the parietal lobe of the brain and then recognized in consciousness by some higher center or group of centers; that it is lost if tactile sense is lost, is greatly impaired or lost if localization-sense is lost, and is usually, but not always, disturbed if the muscular sense is lost.

The nature of the stereognostic sense, upon which the faculty of orientation is in all probability based, is still thrown open to question by the doubt cast at the present d y upon the existence and nature of the muscular sense. This latter sense receives much attention in neurologic literature, though physiology has not yet fully recognized the existence of such a special form of sensation. Since Bell's first mention of it, there have been promulgated many views to explain the perception of active and passive motion, resistance, weight, solidity, volume and position. Some are inclined to regard it as an elementary sense inherent in the muscular fibers, or at least dependent on special nerves going to those fibers. Lewinski argued that the muscular sense was merely the sense of motion perceived by the tactile organs found in and around the articular surfaces of the joints. Schiff taught that the tactile organs in the skin overlying the contracting muscles, gave rise to the sense of active and passive movement. Others demonstrated that the muscular sense depended on a multiplicity of indistinct sensations, localized in the body segments, articulations, muscles and skin, the skin being by far the most prominent. It was taught by the psychic school that the sense of muscular activity is really due to a central perception of the effort exercised at the periphery; that there is a conscious perception of the muscular conditions in general; and that of course any change in those conditions will immediately be recognized and correlated in the sphere of consciousness. In 1893 Wundt declared that the muscular sense was in no way to be attributed to the exercise of the muscles, but rather to the "cellular function of the motor zones" in the cortex. Oppenheim recommends that the term "muscular sense" be dropped entirely; for, according to the definition by Goldscheider, it includes the sensation of passive movement, the sensation of active movement, the sensation of heaviness and resistance, and the sensation of position.

In a recent and noteworthy monograph Bonnier[2] frankly declares that there is no special muscular sense, but that the so-called muscular sense and all it includes is nothing more nor less than a modified form of ordinary tactile sense. We have a sensation of attitude or variation of attitude, due to a sensation of segmental or peripheral activity, and a sensation of central activity or innervation. This segmental sensation is an internal tactile sense—articular, aponeurotic, ligamentous, muscular, etc.—and is merely an adaptation and transformation of the external tactile sense. It is comparable to the involution of the tegumentary structures recognized in the evolution of the eye, ear and other special senses. The stereognostic sense, therefore, as well as the sense of orientation in its large acceptation, and even the abstract notions of time and space are, according to these views, to be attributed, in their last analysis, to the fundamental, universal, simple sense of touch.

BACTERIOLOGY OF INFECTIONS OF THE URINARY TRACT.

The bacteriology of infections of the urinary tract is a rather new subject. Thomas R. Brown[3] makes a report of an investigation of this subject in women, which was made under exceptionally favorable conditions. Most of the acute cases were post-operative and the conditions surrounding the infection were carefully studied; careful cystoscopic examinations were made in all the chronic and most of the acute cases; and thirdly in all suspected renal infections the urine was obtained directly from the kidneys by ureteral catheterization. A brief summary is given of the more important findings as the complete paper will be published later. The cases of cystitis are divided into acute, chronic and tuberculous. The cases of acute cystitis are of great interest because in twenty-four of twenty-six the infection was post-operative, the urine having been examined bacteriologically immediately preceding the operation. These cases, therefore, throw needed light on the question which micro-organisms bring on infection. B. coli communis was found fifteen times, the white pus coccus five times, the yellow twice, the bacillus pyocyaneus, typhosus, and proteus vulgaris once each. In all these cases the urine was acid except the one due to B. proteus vulgaris. Catheterization is held responsible for the infection, although the procedure was carried out with great care. The usually low pathogenic power of these organisms emphasize the importance of other and accessory etiologic factors, the most important, according to Brown, being anemia, pressure on the bladder, sagging of the bladder, trauma and catheterization with poor technique.

Thirty-one cases of chronic cystitis were studied with approximately the same general results as in the series of acute cases. In 7 a pyelitis coexisted. There were 6 cases of tuberculous cystitis, the majority being associated with tuberculous pyelitis or pyelonephritis. The urine was acid, usually rich in pus and red blood-cells.

---

[1] Jour. of Nerv. and Ment. Dis., March, 1899.

[2] L'Orientation, par le Dr. Pierre Bonnier. Scientia: Biologie, No. 9, Paris, April, 1900.

[3] Johns Hopkins Hospital Bulletin, 1901, xii, 4.

The cases of pyelitis and pyelonephritis are of exceptional interest because the urine was obtained directly from the kidney, and usually from both kidneys, so that the two sides could be compared. The only two acute cases were secondary to vesical infection with B. coli. Twelve chronic cases were studied and 5 of these were evidently ascending ureteral infections. B. coli was present in 6 cases, B. proteus vulgaris in 3, and a white staphylococcus in 2, one case showing sterile urine. In the cases not due to B. coli, the urine was alkaline and in all a renal calculus of calcium and magnesium phosphates and carbonates was present. This shows in a striking manner the relation between infection and calculus formation. Six cases of tuberculous pyelitis and pyelonephritis were met with, all associated with the tubercle bacillus in pure culture.

These details are given to show the general trend of the results obtained by this interesting work. In the discussion, Dr. Young refers to dissimilarity of the results obtained by him in a similar study in the male. Young has found a much greater number of different bacteria and among them the gonococcus several times. Gonococcus infections of the bladder are more frequent in men than women, owing to the greater severity of gonococcal urethritis in the former. The ease with which the male bladder may be aspirated for cultures offers good opportunities for studying gonococcal and other vesical infections.

As pointed out by Welch, it would be a one-sided view which failed to take into consideration in the etiology of cystitis and pyelitis the non-bacterial factors, because the bacteria found in the urinary infections have ordinarily very limited pathogenic activity. Finally, it may be mentioned that Hunner refers to 3 cases of pelvic stone associated with streptococci.

Enough has been mentioned to indicate that observations are accumulating which will do much to clear up the various unsettled contentions in regard to infections of the urinary tract and to place our therapy on a safe basis.

THE BACHELOR'S DEGREE AND THE MEDICAL COLLEGE.

The question whether the bachelor's degree should be required for admission to professional schools was considered at a conference of educators recently held in Chicago, and was the special topic of an after-dinner speech by Prof. Ira Remsen of Johns Hopkins University. This problem, while seemingly simple, is in reality quite complex. As Professor Remsen said, there is a great difference between B. A. degrees, the difference depending largely on the college from which the degrees are obtained. A bachelor of arts from a really first-class institution has had, it may safely be asserted, a broader and a more complete training than has one who has obtained a similar degree from some ill-equipped school unfortunately dubbed a college and authorized to grant degrees, but which is little more than a high school or seminary.

If a bachelor's degree could have some definite meaning attached to it, by an agreement among the colleges and universities, as to requirements, it could be unhesitatingly accepted as proof of qualification for admission to the medical or other professional school.

There is, however, another point to be considered. With the liberty allowed a student in our first-class institutions, it is possible for a man to graduate without having taken those studies best fitted to enable him to pursue most advantageously his subsequent medical course. A student may have taken, as his elective studies, only French or mathematics, or astronomy, or geology, and yet be graduated *magna cum laude* with the bachelor's degree, and claim a right to enter the medical college. It is clear that he would be better fitted had he devoted some of his time to certain other branches, as biology, chemistry, botany, physics, etc. It follows that the faculty of the medical college has a right to ask those who apply for admission on the B. A. degree not only from what college they come, but what studies have been taken in order to secure the degree.

This leads to a consideration of the important topic of premedical courses in our literary colleges. Should not students who contemplate the study of medicine be early guided into courses especially adapted to prepare them for the medical college, into physics, chemistry, biology, with histologic technique, German and French studies that can be made to have a cultural influence as well as philosophy, Greek, or higher mathematics? And should not the student in a university in which the medical school is a part of that university receive credit in both the literary and the medical departments for certain work? This is already done to a certain extent at not a few universities, so that when a man takes his bachelor's degree in art or science, he has also credits in his medical course for one or even two years' work.

LEGISLATION ON HYPNOTISM.

A bill has been introduced in the New York legislature for regulating the practice of hypnotism, mesmerism, suggestive therapeutics, and allied phenomena. License is required from the Board of Regents of the University, and to obtain it a good general education and at least two years in a medical school are required. Any unauthorized practice or advertising of ability for such is to be made a misdemeanor, and penalties of fine and imprisonment are provided for by the act. In regulating the therapeutic and otherwise employment of hypnotism, New York State will have a precedent in the legislation or local ordinances of several European countries which have prohibited the unauthorized practice of inducing the hypnotic condition. Its possible dangers are sufficiently well known, moreover, to fully justify the proposed measure.

ONTARIO'S VITAL STATISTICS.

The Registrar-General of the Province of Ontario recently published the complete returns of births, marriages and deaths, which are considered encouraging by the *Toronto Globe,* inasmuch as an increase of births is reported over the preceding year. The increase, however, is not great and still leaves the ratio lower than that of almost any other region of equal extent, viz., 19.9 per 1000, and less than that of 1898. It is to be presumed that vital statistics are kept more carefully in Canada than in some portions of the United States, but some of the small increase is attributed by the *Globe* to prosecutions of parents for neglecting to register the birth of offspring. Admitting a certain proportion of births not registered, the ratio is not encouraging, and the steady decrease of late years, only interrupted by the slight rise, is still less so. Even in the worst parts of the United States in this respect the birth-rate has not fallen so low as in Ontario. Though there, as elsewhere with a low birth-rate, the death-rate is still lower, the population would seem to be very nearly in a static condition, which from a political point of view is hardly a desirable one. The cause suggested by the Registrar, viz., the preponderance of the rural population, farm life not being conducive to early marriages, does not strike at the root of the matter. It would be better to assume an ideal of living generally above the universal possibilities, and this would apply as well to the town as to the rural population. The absence of a proletariat, while it indicates thrift and comfort, destroys the aggressiveness of a people and is a symptom to a certain extent of national decadence. Ontario seems, as far as this sign is indicative, to be approaching that condition.

OSTEOPLASTIC CARCINOMA.

In 1891 von Recklinghausen directed attention to the development of osseous metastases in primary carcinoma of the prostate gland. He showed that the metastases were associated with the new formation of bone. Since then several additional cases have been reported, and recently Erbslöh described five cases of osteoplastic carcinoma from von Recklinghausen's laboratory.[1] Three cases occurred in men, the primary tumors being prostatic, and two in women, the carcinoma in one being primary in the stomach, in the other in the bile-ducts. In all these cases the carcinoma had a marked tendency to infiltration. The metastatic nodules in the bones contained newly-formed osseous substance. The microscopic appearances indicated that the metastatic growths began in the form of an intracapillary infiltration which resulted in closure of the capillaries and passive congestion, the latter being regarded as the determining cause of the new formation of bone. Side by side with the osteoplastic process may be resorptive processes, which render the bone soft and porous. As far as can be told at the present time, the spinal column is the most frequent seat of this interesting metastasis, then come the ribs, the proximal end of the femur, the pelvis, the skull, the sternum, the humerus, and the radius, in the order named. It seems as if the cells circulating in the blood were arrested in the wide and sluggish capillaries of the bones. The only other metastases in these cases—except in one—were situated in the regional lymph glands. This remarkable peculiarity of certain carcinomas, especially those developing in the prostate gland, should be borne in mind in the clinical study of prostatic tumors.

A TREATY OF SANITARY PROTECTION.

Two South American States, Argentina and Uruguay, have made, what is perhaps a novelty in diplomacy, a treaty of sanitary alliance and protection as regards infectious diseases, especially bubonic plague. It provides for mutual provisions for inspection and quarantine arrangements sufficient to protect either country from invasion of disease from the other without any undue interference with communications or commerce, such as might easily occur were the efforts made independently by either without regard to the actions of the other. Each country is to be in its way the guardian of the other's health as well as of its own, and to cordially co-operate in all necessary measures. The advantages of such a mutual arrangement carried out in good faith are obvious; it would be well could treatises in regard to sanitation become universal. A uniform system of notification and in and out inspection throughout the world, though like every other good thing it might find its opposers, would be a step toward the millenium. At present each leading government keeps its sanitary spies on the others in the way of consuls, etc., and our own government has a corps of medical officers stationed in various parts of the world to supplement its regular consular officials in their lookout for disease that might be transmitted to us. Probably this will always be more or less of a necessity, but such treaties as the one referred to are steps in advance that give encouragement of better things in the future. That it is between two Spanish-American countries is evidence that in medical matters, however it may be in general political management, they are progressive and enlightened. What they do for and between themselves in this direction will undoubtedly aid in the protection of other countries, which in fairness should reciprocate and co-operate in the good work. Sanitary alliances are apparently a new thing in international law; they are unmentioned in most if not all text-books on the subject, but they are an innovation that is to be commended and it is to be hoped has come to stay.

PRACTICE ACTS AND RELIGIOUS LIBERTY.

The argument that medical practice acts interfere with religious liberty guaranteed by the constitution is an old one, but it still seems to be in use. The spiritualists and "Christian Science" people always make the most of it, and it does not appear to relieve the case much for them when, as in the Missouri law just passed by the legislature, they are allowed to practice provided they make no charges for their services. The remuneration is the important feature of the religious liberty of which the law deprives them; their religion, in its essentials, is like that of the sailor who, when in extremity, not knowing how to pray, preach or sing, passed the hat for a collection. The opposition to the ciated with tuberculous pyelitis or pyelonephritis. The urine was acid, usually rich in pus and red blood-cells.

---

[1] Virchow's Archiv, 1901, clxii, 20-44.

The cases of pyelitis and pyelonephritis are of exceptional interest because the urine was obtained directly from the kidney, and usually from both kidneys, so that the two sides could be compared. The only two acute cases were secondary to vesical infection with B. coli. Twelve chronic cases were studied and 5 of these were evidently ascending ureteral infections. B. coli was present in 6 cases, B. proteus vulgaris in 3, and a white staphylococcus in 2, one case showing sterile urine. In the cases not due to B. coli, the urine was alkaline and in all a renal calculus of calcium and magnesium phosphates and carbonates was present. This shows in a striking manner the relation between infection and calculus formation. Six cases of tuberculous pyelitis and pyelonephritis were met with, all associated with the tubercle bacillus in pure culture.

These details are given to show the general trend of the results obtained by this interesting work. In the discussion, Dr. Young refers to dissimilarity of the results obtained by him in a similar study in the male. Young has found a much greater number of different bacteria and among them the gonococcus several times. Gonococcus infections of the bladder are more frequent in men than women, owing to the greater severity of gonococcal urethritis in the former. The ease with which the male bladder may be aspirated for cultures offers good opportunities for studying gonococcal and other vesical infections.

As pointed out by Welch, it would be a one-sided view which failed to take into consideration in the etiology of cystitis and pyelitis the non-bacterial factors, because the bacteria found in the urinary infections have ordinarily very limited pathogenic activity. Finally, it may be mentioned that Hunner refers to 3 cases of pelvic stone associated with streptococci.

Enough has been mentioned to indicate that observations are accumulating which will do much to clear up the various unsettled contentions in regard to infections of the urinary tract and to place our therapy on a safe basis.

THE BACHELOR'S DEGREE AND THE MEDICAL COLLEGE.

The question whether the bachelor's degree should be required for admission to professional schools was considered at a conference of educators recently held in Chicago, and was the special topic of an after-dinner speech by Prof. Ira Remsen of Johns Hopkins University. This problem, while seemingly simple, is in reality quite complex. As Professor Remsen said, there is a great difference between B. A. degrees, the difference depending largely on the college from which the degrees are obtained. A bachelor of arts from a really first-class institution has had, it may safely be asserted, a broader and a more complete training than has one who has obtained a similar degree from some ill-equipped school unfortunately dubbed a college and authorized to grant degrees, but which is little more than a high school or seminary.

If a bachelor's degree could have some definite meaning attached to it, by an agreement among the colleges and universities, as to requirements, it could be unhesitatingly accepted as proof of qualification for admission to the medical or other professional school.

There is, however, another point to be considered. With the liberty allowed a student in our first-class institutions, it is possible for a man to graduate without having taken those studies best fitted to enable him to pursue most advantageously his subsequent medical course. A student may have taken, as his elective studies, only French or mathematics, or astronomy, or geology, and yet be graduated *magna cum laude* with the bachelor's degree, and claim a right to enter the medical college. It is clear that he would be better fitted had he devoted some of his time to certain other branches, as biology, chemistry, botany, physics, etc. It follows that the faculty of the medical college has a right to ask those who apply for admission on the B. A. degree not only from what college they come, but what studies have been taken in order to secure the degree.

This leads to a consideration of the important topic of premedical courses in our literary colleges. Should not students who contemplate the study of medicine be early guided into courses especially adapted to prepare them for the medical college, into physics, chemistry, biology, with histologic technique, German and French studies that can be made to have a cultural influence as well as philosophy, Greek, or higher mathematics? And should not the student in a university in which the medical school is a part of that university receive credit in both the literary and the medical departments for certain work? This is already done to a certain extent at not a few universities, so that when a man takes his bachelor's degree in art or science, he has also credits in his medical course for one or even two years' work.

The argument that medical practice acts interfere with religious liberty guaranteed by the constitution is an old one, but it still seems to be in use. The spiritualists and "Christian Science" people always make the most of it, and it does not appear to relieve the case much for them when, as in the Missouri law just passed by the legislature, they are allowed to practice provided they make no charges for their services. The remuneration is the important feature of the religious liberty of which the law deprives them; their religion, in its essentials, is like that of the sailor who, when in extremity, not knowing how to pray, preach or sing, passed the hat for a collection. The opposition to the

---

1. Virchow's Archiv, 1901, clxii, 20-44.

Missouri bill, however, as well as to a similar act just passed by the Indiana legislature, appears from an unexpected source; it is said that Catholic influence has been exerted against the medical practice act in those states. We have too good an opinion of the general good sense of the higher authorities and leaders in the Catholic or any of the Protestant churches to believe that they are at all responsible for such an action; it must be, if the reports are true, only a misled zeal of some of their more poorly informed adherents. "Christian Science," so far as its misty theology can be interpréted, involves the nullification of human responsibility and thus strikes at the basis of all religion. It is, as has often been said, neither Christian nor scientific, and is therefore without any claims for consideration on either side. Religious rites for the sick, as they are practiced in the Catholic church, are, as is generally understood, for the good of the soul, and therefore do not come properly under the prohibitions of the legal regulation of medical practice. The Catholic church does not teach dependence upon them to the exclusion of other measures, or that they are alone directly efficacious for bodily ills. That Catholics, therefore, should oppose medical laws, is not to be expected, and if they do so it must be attributed to individual ignorance, not to the church as a whole.

HAYCRAFT'S REACTION FOR BILE.

When sublimed sulphur—"flour, or flowers, of sulphur"—is added to urine containing bile, the sulphur immediately falls to the bottom of the tube. In the absence of bile the sulphur remains on the surface of the urine, sinking but partially or very slowly, if at all. This is Haycraft's reaction for biliary acids. This simple method, known to Eichhorst in 1887 and mentioned in the Physiology of Langlois and de Varigny in 1893, seems to have fallen into complete oblivion. The original publication of Haycraft, an English chemist, has been searched for in vain by Frenkel and Cluzet who, attracted by the interesting physical problems involved in the reaction and by its practical value, have studied the phenomenon both clinically and experimentally.[1] They find that Haycraft's reaction for biliary acids is an extremely simple method for determining the presence of bile in the urine and in certain other organic liquids. Its sensitiveness compares favorably with that of Pettenkofer's method and of Strassburg's modification of the latter, but it is not absolutely pathognomonic; for there are a number of other substances which also cause the sulphur to precipitate, such as acetic acid, alcohol, ether, chloroform, essence of turpentine, benzoin and its derivatives, phenol and its derivatives, anilin, and the soaps. In the case of urine, however, Haycraft's method is of great usefulness for the very reason that the substances just enumerated occur but exceptionally in the urine, and hence only rarely will they simulate the presence of the biliary acids. Frenkel and Cluzet state that Gmelin's test and Pettenkofer's and Strassburg's reactions may fail to indicate bile where sulphur gives a positive result. In the case of the contents of the stomach or of the intestines, the reaction with sulphur has not so much value because of the frequent presence of acetic acid, alcohol, and phenol and its derivatives, all of which throw down the sulphur.

Haycraft's reaction is explained by differences in surface tension. The authors have determined that all fluids with a surface tension greater than 50 dynes per centimeter do not allow sulphur to fall, and that in all fluids with a tension less than 50 dynes the sulphur rapidly settles. When the tension is about 50 dynes, the reaction is doubtful. Incidentally they observed that lycopodium bears the same relations to fluids with a tension of 30 dynes, as flowers of sulphur to fluids with a tension of 50.

A THEORY OF RELAPSES IN FEVERS.

In certain disease, such as typhoid fever, antibacterial substances, often in considerable quantity, appear in the blood toward the end of the fever and in convalescence. It is not unlikely that these substances begin to be formed soon after infection. The appearances of other substances, such as agglutinins, indicate that specific changes are taking place in the tissues and fluids of the affected organism. That relapses should occur, as they frequently do, in individuals whose blood contains substances inimical to the specific bacterium of the disease in question is certainly at first sight not clear. This question is discussed by Herbert E. Durham.[1] He bases his theory of relapse in fevers upon the consideration that a given infection is not to be regarded as the result of the action of a number of actually identical organisms, but rather as the result of the combined action of closely similar though not absolutely identical agents. Now, if the infecting agents consist of varieties and subvarieties, then the resulting antibodies in the serum may vary more or less in their general constitution corresponding to the varieties and subvarieties of the micro-organisms at work. The individual may become highly protected against a particular variety of pathogenic agent, whereas other varieties may multiply quite unchecked and thus cause a relapse. Is this refinement of bacterial variability a mere creation of fancy or does it rest upon actual observations? Durham thinks that such varieties as here supposed have been shown to exist. Pfeiffer and Kolle have found that the protective power of typhoid serum varies with different test cultures, and not only quantitatively but also qualitatively. There are also marked differences in the reaction of agglutination in different races of bacilli and different samples of serum. In studying different colonies of B. enteritidis (Gärtner) obtained from a fatal case of meat poisoning, Durham found that the bacilli in one colony were peculiarly aberrant in their behavior toward the serum from some of the individuals who had suffered from the poisoning. And two of the serum samples, which agglutinated the atypical bacillus, had comparatively less effect upon the other cultures. This points to a "varietally different" infection to that of the other patients. The aberrant culture was not more virulent than the other cultures. The problem ought to be studied by means of tests of the actual conditions in relapses in such disease as typhoid fever. Serum should be tested, as suggested by Durham, before, during and after relapses, upon a varied selection of cultures, both for agglutinating and protective powers. The literature of antistreptococcic serum contains much evidence confirmatory of the view advanced by Durham. Van der Velde has shown that the serum of a streptococcus-treated animal contains pronounced protective powers against a particular race of streptococci, but not against other races. Clinical experience shows that erysipelas is very likely to recur, and perhaps the renewed outbreaks are caused by streptococci that differ somewhat in character from the streptococci of the original attack. There is consequently considerable evidence to indicate that relapses may depend upon the varying preponderance of varietal forms, each capable by virtue of its complex structure to cause more or less specific antibodies. There are so many factors in the pathology of an infective disease that it is exceedingly difficult to determine the part of each in the final result. Bacterial variability seems to be competent to clear up some of the difficulties in the way of a clear understanding of relapses in fever.

Medical News.

ALABAMA.

West Huntsville has closed its smallpox hospital, as no new cases have developed in the last three weeks.

Dr. Thomas W. Ayers, wife and family left Anniston, March 9, and sailed from San Francisco, March 15, for China, where Dr. Ayers is to be stationed as a medical missionary.

Two Birmingham physicians have been fined $1 each for violating the city ordinance by failing to notify the city physician and county health officer, at once, on finding a case of contagious disease.

Hillman Hospital, Birmingham, received an addition of more than $6000 to its building fund in response to appeals made at a recent mass meeting. The assets of the hospital now exceed $31,000, not including a maintenance fund of $20,000, presented by Mr. Hillman.

CALIFORNIA.

A detention hospital for contagious diseases is said to be the most pressing need of Los Angeles, and the board of health has been petitioned to take steps to establish such an institution.

A "nervopathist," of Los Angeles, who was fined $100 a short time ago for practicing medicine without a license, and who appealed, has had the judgment of the lower court affirmed by the supreme court.

A leper, who had been selling candy in San Francisco since November, was taken from his place of business March 12 and admitted to the Harbor Hospital, whence he will be taken to the hospital for lepers.

The German Hospital, San Francisco, has invited architects to present competitive designs for the new hospital building, on which $250,000 is to be expended. Prizes of $2000, $1000, $750 and $500, respectively, are offered for the four best designs.

Seven graduates of the Pacific Coast Regular College of Medicine, comprising the first graduating class of that institution, which began its work only about nine months ago, have been refused licenses to practice by the board of medical examiners of the Medical Society of the State of California, on the ground that their Alma Mater does not meet with the minimum requirements for medical colleges, as adopted by the board Dec. 4, 1900.

COLORADO.

Dr. Uhler D. McDowell, Longmont, has been appointed medical inspector to the State Board of Health.

Lake City is to have a hospital, through the generosity of Col. C. F. Meek, who has purchased a suitable building and turned it over to the people of Hinsdale County for hospital purposes.

A compromise has been effected regarding the Denver & Rio Grande Railroad Hospital at Salida which is satisfactory alike to the officials and the employees of the railroad. By its provisions Dr. Frank N. Cochems is made surgeon-in-charge, with authority only limited by the trustees of the employees relief association.

An antivaccination circular is being distributed by the Colorado Medical Liberty League, signed by two "doctors," one of whom is a magnetic healer and the other is not known to the medical directory. Unfortunately, however, this propaganda makes the enforcement of the orders of the health commissioner regarding vaccination more difficult.

ILLINOIS.

St. Anthony's Hospital, Rock Island, held the annual meeting of its surgical staff, March 8, and re-elected Dr. George L. Eyster, president; Dr. Joseph R. Hollowbush, vice-president, and Dr. St. Elmo M. Sala, secretary and treasurer.

Chicago.

Dr. E. C. Dudley is taking a vacation tour on the Pacific coast.

Dr. Frank Billings has returned from a yachting trip of a month in the tropics.

"Dr." Gee Wo Chan, a Chinaman, has been prosecuted by the State Board of Health for omitting to comply with the formalities required by law before practicing medicine.

Dr. Gerry S. Driver, acting asst.-surgeon, U. S. Army, who has been stationed at Chicago for some time, has been made captain and asst.-surgeon of Volunteers, and ordered to the Philippine Islands.

Pneumonia Mortality.—The enormous increase of pneumonia mortality within the past decade is due to the fatal complications of influenza, the germ of which disease has been present in this city to a greater or lesser extent ever since 1890. The sufferer from pneumonia now has a much poorer chance of recovery than he would have had a dozen years ago, when there was no influenza infection in the air.

Chicago's Mortality.—The mortality last week was lower than for the week previous, and restores the average of eight weeks of unprecedentedly low winter mortality. There were 443 deaths from all causes, 35 fewer than the previous week and 104 less than the corresponding week of 1900. The death-rate was 13.14 per 1000 per annum for the week ended March 16. Of the 443 deaths, 104 were of infants under 1 year old and 88 of individuals over 60. Respiratory diseases caused 167 deaths and violence 24. On the basis of the first sixteen days of the month, the total March mortality will be only 1910, as against 2547 in 1900, 2343 in 1899, and 2316 in 1898. Taking the increase of population into consideration, this will make a remarkable showing for March, 1901. The most satisfactory and the most unlooked-for decrease is in the deaths from pneumonia, which were 13 less than the previous week and 48 fewer than in the corresponding week one year ago. The total pneumonia deaths for the month, up to the close of last week, number 161, on which basis the total for the month would be 328, as against 564 in 1900, 468 in 1899, and 378 in 1898.

INDIANA.

Riley has an epidemic of measles. One physician in the town reported 83 cases to the County Board of Health in February.

Dr. John A. Martin, for several years asst.-surgeon at the State Soldiers' Home, Lafayette, has been made surgeon-in-charge, vice Dr. Theodore Sargent, who resigned on account of ill health, but who will remain at the home as assistant-surgeon.

IOWA.

Cedar Rapids is to have a public hospital. Abraham Slimmer, of Waverly, has agreed to duplicate, up to $50,000, any amount the city may raise for this purpose. About $25,000 has been secured up to this time.

LOUISIANA.

Dr. Joseph A. O'Hara, New Orleans, has been appointed medical inspector of public school children by the local board of health.

Dr. D. U. Maes has been appointed assistant-demonstrator of anatomy, New Orleans College of Dentistry, vice Dr. Emil Regard, resigned.

The annex to the State Insane Hospital, for colored patients, has been constructed at a cost of $18,000, and on the day it was opened fifteen patients were received.

The State Board of Health has appointed Drs. David P Albers, William H. Carson, W. S. Cushman, J. E. Heidingsfelder, G. King Logan, and W. J. Rhymes medical inspectors on the fruit vessels plying between New Orleans and Central American ports.

Appointments as Internes.—On competitive examination, the following undergraduates of the medical department of Tulane University have been chosen to serve as internes in the Charity Hospital for two years from April 1: W. R. Callen, P. C. De Verges, A. C. Eustis, E. M. Hummel, A. C. Jacoby, R. C. Lynch, J. F. Points, and S. K. Simon.

Tuberculosis Camps.—There is a movement on foot to establish hospital camps for the tuberculous in the pine woods near Covington, St. Taminary Parish. Already a fifty-acre tract of land and $800 have been donated for the purpose, $300 of the latter having been given by members of the State Board of Health.

MARYLAND.

Smallpox.—Early in March a report came to the State Board of Health of the prevalence of an outbreak of supposed chicken-pox in Sussex County, Delaware, which borders on Maryland. A case was found on board a vessel in the harbor of Cambridge, Md., which was diagnosed by Drs. Mace and Goldsborough, of that place, as smallpox. Dr. John S. Fulton at once warned all county health officers of the Eastern shore, and also notified the Delaware officials of the discovery. It was then found that there were fifty or sixty cases, chiefly among negroes, at Seaford, Del. The disease is said to be of a mild type.

Baltimore.

Dr. Bosley, health commissioner, has had introduced into the city council an ordinance appropriating $25,000 for an infectious diseases hospital.

MICHIGAN.

Smallpox in Flint has assumed alarming proportions. Many cases have been reported, more than 100 are in quarantine, and this within ten days. All business is at a standstill.

Dr. Henry D. Thomason, Albion, who served during the Spanish-American War as major and surgeon of Volunteers in the South, Cuba and the Philippines, and returned to the United States a few months ago, has been re-appointed major and surgeon, U. S. V., and is on his way to his post of duty in Manila.

The State Mortality.—For February this was at the rate of 17.1 per 1000 per annum. There were 472 more deaths than in the corresponding month of 1900. There were 536 deaths of infants under 1 year of age, 185 of children 1 to 4 years old, and 1029 of persons 65 years and over. Important causes of death were as follows: Tuberculosis, 184; typhoid fever, 43; diphtheria and croup, 47; scarlet fever, 34; pneumonia, 474; influenza, 378; cancer, 121; violence, 100.

Hospital for Consumptives.—A bill has been introduced in the legislature, by Dr. Ames, to establish and maintain a state hospital for consumptives. It provides that the objects of the hospital shall be the proper care and treatment of consumptives; the training and education of those who leave the hospital in the restriction of the spread of the disease; the training of medical students in the methods of restricting tuberculous disease, and that physicians and others may be enabled to study the disease with a view to its restriction or extinction in Michigan.

MINNESOTA.

Bethesda Hospital, St. Paul, has paid off $20,000 of its indebtedness, leaving only $5000 outstanding.

Both medical bills, previously noticed in these columns, were defeated in the legislature, after long and fruitless debate, by a vote striking out the enacting clause of each.

A bill has been introduced by which the state hospitals for the insane are to be designated, not as "first" and "second," but by the name of the city in which *they are located. The* bill also provides for $200.000 to be used for the construction of two cottages at Anoka and two at Hastings.

NEW JERSEY.

Many physicians from various parts of the state gathered at Trenton to urge the appropriation of funds for the construction of a sanitorium for consumptives.

The State Hospital at Morristown is at last completed, at a cost of $500,000, or more than $5000 per bed. The formal opening will be deferred until later in the spring.

Smallpox has appeared in Hudson County, and at Mount Laurel. General vaccination has been recommended in the latter place, and in Paterson. The quarantine has been raised against certain districts of Woodbury, where smallpox has prevailed.

Regulation of Anatomy Courses.—A bill has been introduced in the house prohibiting any institution that gives instruction in human anatomy from graduating pupils in less than two years. It was referred to a committee and promptly reported with a favorable recommendation for its passage. The bill is aimed at a school in Trenton which advertises to teach its system of curing without drugs in ten months. Because it does not prescribe drugs in any way the school is exempt from examination by the State Board of Medical Examiners.

NEW YORK.

Dr. Ethan A. Nevin, Ogdensburg, has been appoinfed junior physician at the Long Island State Hospital.

The Amsterdam City Hospital staff met March 5 and elected Dr. Charles Storer consulting physician. Dr. James B. Conant was nominated on the staff, and Dr. Edward J. Collier appointed pathologist.

The bill giving the State Board of Health power to regulate the type and leading of books, newspapers and serial literature, to protect the public eyesight, has been reported favorably by the public health committee of the assembly.

Medical Examiners.—The following were appointed by the board of regents, at its meeting in Albany, March 14: Drs. Joseph P. Creveling, Auburn, and Eugene Beach, Gloversville; Drs. W. Gilman Thompson, Cornell Medical School, and Willis G. Tucker, Albany Medical School, were appointed members of the medical council for three and five years, respectively.

Buffalo.

Dr. Charles M. Burdick has been appointed medical interne in the St. Lawrence State Hospital.

The monthly report of the department of health for February shows a death-rate of 13.43 per 1000 per annum.

New York City.

A New Hospital.—The Hebrew Benevolent and Orphan Asylum Society will build a five-story hospital at the northeast corner of Amsterdam avenue and 136th street. It will adjoin the present building and will cost $70.000.

A Brooklyn policeman, exposed as a guard in a tenement district where quite a number of smallpox cases had appeared, has been sent to North Brother Island suffering from the disease. Other cases have appeared in Brooklyn.

A Projected Nurses' Home.—On March 11 plans were filed for the new nurses' home for the Presbyterian Hospital, to occupy a plot 124 by 102 feet on a site opposite the hospital. The structure is to be eight stories, paid for from a fund of $300,000 provided by the munificence of John Stewart Kennedy, president of the board of managers.

OHIO.

Dr. Homer C. Bennett, Lima, suffered a loss of about $1000 by fire, March 12.

Township physicians have been appointed as follows: Drs. Edward A. Flinn, Madisonville, and Ulysses G. Senour, Pleasant Ridge.

Dr. James F. Edwards, formerly of Portsmouth, but now an acting assistant-surgeon on duty with the 32d Regiment, U. S. V., in the Philippines, has been commended for conspicuous gallantry on the field of battle and recommended for promotion.

Lakeside Hospital, Cleveland, has selected the following house staff from the graduating class of Western Reserve Medical College: A. H. Bill and C. B. Wean, medical service; P. P. Carlisle, C. H. Hay, A. C. Ludlow and L. B. Zintsmaster, surgical; C. S. Hoover and D. W. Pepper, gynecology, and E. M. Ickles, private ward.

Meat Regulation.—Health Officer C. W. Davis, Cincinnati, has transmitted to the board of public service an ordinance providing that no person shall expose for sale any sheep, goat, lamb or kid that has been slaughtered, until the head, feet, etc., have been removed. The statement is made that meat from which the head, feet, etc., are not removed is liable to contain "germs and vermin."

St. Joseph's Hospital, Lorain, has organized its medical staff as follows: Dr. Abraham N. Garver, president; Dr. Olney B. Monosmith, secretary; Drs. William E. Wheatley, Samuel S. Cox, John F. McGarvey and Abraham N. Garver, on the surgical staff; Drs. Edward V. Hug, Charles H. Frederick, Frank Young, John R. Gilbert and H. P. Robinson, on the medical staff, and Drs. Olney B. Monosmith, Lorain, and H. Wooster Patrick, Elyria, in the eye, ear, nose and throat department.

PENNSYLVANIA.

Dr. J. Ralph Shook, Greencastle, has received an appointment as acting assistant-surgeon *in the army*.

Dr. Andrew Strang, for many years resident physician at Hillside Home, Scranton, has resigned and will spend several months abroad.

The State Hospital for the Insane at Norristown is so overcrowded, despite the two new buildings, that on March 1 260 patients were sleeping in corridors, 150 of whom had only mattresses on the floor.

The legislature has been asked for an appropriation of $60,000 for the establishment of free homes for consumptives in the mountains near White Haven. The idea at present is to erect about ten cottages where these patients may be treated.

The will of Christopher L. Magee, of Pittsburg, provides for the founding of a general hospital, to be known as the Steel-Magee Hospital, in honor of the testator's mother. The interest on $10,000 was also given to Mercy Hospital, of Pittsburg.

Fire in Hospital.—On March 11 a fire occurred in the Beaver County Hospital, at Rochester, and destroyed the first floor of the building. The hospital was completed last July, at a cost of $4000. The total loss will aggregate $3000. The patients were transferred to the Beaver Valley Hospital at New Brighton.

Warrants have been issued by Coroner Roberts, of Scranton, for the arrest of four "Christian Scientists" for alleged criminal negligence in the case of a man who recently died there while under their treatment. One of the accused is said to have received $1 a day for his services, and as he has no license to practice medicine, may be prosecuted.

Philadelphia.

Gifts.—By the will of George M. Troutman, $5000 has been given the *Presbyterian Hospital* for the endowment of a free bed; $1000 to the Maternity Hospital of Philadelphia, $1000 to the Northern Dispensary of Philadelphia, and $5000 to the Philadelphia Home for Incurables.

Hospital Funds.—The recent charity ball realized $11,200, which was equally divided between the University of Pennsylvania Hospital, the Maternity Hospital of the Jefferson Medical College, the Orthopedic Hospital and Infirmary for Nervous Diseases, and the Samaritan Hospital.

Free Hospital for Poor Consumptives.—This institution has announced that the total receipts for the year were $10,237.65, and the expenditures $10,048.27. The sum of $3327.14 was received through small contribution boxes placed in different portions of the city. The board of managers has purchased 215 acres of land in the Pocono Mountains, on which to erect a sanitarium. At the present time the patients are being treated in the University, German, St. Agnes', Rush and St. Mary's hospitals. It is hoped that the management will soon be able to erect a building of its own in the city. Dr. Lawrence F. Flick was re-elected president.

Tuberculosis Contagious.—The board of health has placed tuberculosis on the list of contagious diseases, and decreed that physicians treating such cases must report them. It is *not* the intention to isolate cases of tuberculosis, or to placard their houses. The work of the board will be educational, and will consist in sending to these patients instructions regarding certain precautionary measures to be instituted in order to prevent others from contracting the disease, and in other instances to supply patients dependent on charity with the required medicines. This work, for the most part, has resulted from the efforts of members of the Pennsylvania Society for the Prevention of Tuberculosis and the Philadelphia County Medical Society.

SOUTH DAKOTA.

Dr. Frederick W. Cox, Vermillion, has been appointed acting assistant-surgeon in the army.

The plans and specifications for St. Luke's Hospital building, Aberdeen, have been received and the construction of the hospital will be started in a few weeks.

The bill introduced by Dr. Charles W. Locke, of Minnehaha County, provides that no license shall be issued to any person who has not taken a full four-year course in a recognized medical college.

UTAH.

Smallpox is reported as follows: Salt Lake City, 112 cases, including 56 new cases; Sterling, 1; Eureka and Letitia, each 2 cases.

Dr. Joseph M. Heller, Winchester, late acting assistant surgeon in the army, has been appointed major and surgeon of volunteers, *on the recommendation* of General Otis.

Gunnison children were admitted to school unvaccinated in violation of orders of the State Board of Health, and the health officer, Dr. Hubert F. Andrews, has been instructed to prosecute the persons on whom the responsibility can be fixed.

CANADA.

Montreal's mortality record for the nine weeks following January 5 shows 129 deaths from scarlet fever. During the same time diphtheria only claimed 13.

Smallpox cases now number 136 in the province of Ontario. On March 1 there were 87. The number of cases at Sudbury has increased from 17 to 30.

Dr. Walter Wilkins, one of the resident staff of the Montreal General Hospital, has left for British Columbia, to accept an appointment as surgeon of the Cariboo mines.

An epidemic of scarlet fever is raging in the Baptist college at Woodstock, Ont. There are several hundred students at this institution, and the college is under strict quarantine.

Prof. J. George Adami, of McGill University, Montreal, has been appointed vice-president of the section of pathology and bacteriology of the International Congress on Tuberculosis, to be held in London, England, in July, under the patronage of His Majesty, King Edward VII.

Sanitary Legislation.—A deputation from the National Sanitarium Association waited on the local government recently, seeking an amendment to the sanitarium act, which will allow municipalities to contribute to the support of sanitaria outside the municipalities. If the act were so amended the association would immediately commence the erection of a sanitarium outside of Toronto.

Registration of Births and Deaths Opposed.—The Doukhobors and Gallicians, settled in the Northwest Territories, are commencing to make trouble in the community. They first objected to Canadian marriage laws, and now they are opposing the law in regard to the registration of births and deaths. They have issued "An Address to All Nations," seeking an asylum in a country where these "oppressive laws" do not obtain.

Victorian Order of Nurses.—The annual meeting of the Victorian Order of Nurses was held at Ottawa on March 15. The total receipts for the year amounted to $7638.53, and the expenditure was $5668.76. The Ontario government grants amounted to $2500. Six new branches were supplied with nurses during the year. Since the inauguration of the order, five cottage hospitals have been established in British Columbia and the Northwest Territories. A fund will be established for creating such hospitals, and it is proposed to invite the dominion and provincial governments for contributions for this purpose.

Dominion Medical Council.—On the 13th inst., Dr. T. G. Roddick, M.P., introduced his bill for a dominion medical council into the dominion parliament. In his address to the house, he explained the provisions of the bill, the details of which have already been published in The Journal. In going over the constitution of the board, Dr. Roddick gave a concise history of the repeated attempts to form this council. Each province will be given three members and the homeopaths will also have three representatives. Dr. Roddick gives the medical population of the provinces as follows: Prince Edward Island, 90 practitioners; Nova Scotia, 476; New Brunswick, 243; Quebec, 1400; Ontario, 2500; Manitoba, 344; British Columbia, 314; Northwest Territories, 95. The bill received its first reading.

Scientific Evenings.—Toronto University has inaugurated an *annual series of scientific evenings*, to afford the public an opportunity to become acquainted with the scientific resources of the university. In the physiological department, Prof. A. B. MacCallum and Dr. F. H. Scott exhibited the tracings from the external pulsations of the heart and blood-vessels of the human subject at the session held March 13. Dr. Miller and Dr. Kendrick, of the chemical department, showed experiments illustrating Goldschmidt's method of producing intense heat by the action of aluminum on oxid of iron. Prof. A. Primrose and Dr. Coutts gave a demonstration of the filaria parasite. One was exhibited in the living state, the filaria sanguinis hominis nocturna. Demonstrations were also given in the laboratories on radiographic experiments, microtomy and bacteriology.

Healthy Baking-Powder.—A deputation of the baking-powder men waited on the central government last week. They were accompanied by Dr. Peter T. Austin, a New York chemist, while the Inland Revenue Department was advised by its analysts, Messrs. T. MacFarlane and A. McGill. In a bulletin issued some months ago, noted in The Journal at the time, the employment of alum in baking-powders was condemned as being injurious to health. The contentions of the deputation were that whenever alum is used in making baking-powder it is mixed with bicarbonate of soda and, during the process of baking, goes off in the form of carbonic acid gas, and the residue left is not injurious to health. While a prohibitory law might be justified in England, where they employ a crude alum, it does not maintain in Canada, where the product goes into the manufacture. The deputation was promised a consideration of the question.

FOREIGN.

Dr. Henry Jellett, ex-assistant master of Retunda Hospital, Dublin, has been appointed editor of the *Medical Press and Circular*, to succeed the late Dr. Archibald Hamilton Jacob.

Snake-bites, according to the last annual report of the Indian Government, caused 24,621 deaths in India last year. The mortality from this cause does not seem to diminish in spite of all efforts of the government.

Deaths Abroad.—The death of G. A. Nordlund, professor of anatomy at Upsala, is announced, and that of C. J. Rossander, professor of surgery at Stockholm; of O. von Heusinger, professor of legal medicine and pediatrics at Marburg, and of J. Homan, assistant superintendent of the Kiel Institute of Hygiene.

Death of the Editor of "Vratch."—Prof. V. Manassein, who founded the leading Russian medical weekly, *Vratch*, twenty-one years ago, and has been its editor since, died at St. Petersburg, February 26, of apoplexy. He was in his sixty-first year. He served as professor of therapeutics and internal medicine for twenty-five years, and has published a number of important works.

Progress of the Plague.—According to the *British Medical Journal* of March 9, deaths from plague, for all India, for the week preceding February 9 numbered 4377, as compared with 3415 the previous week. For the week ending February 12, 923 died of plague in the City of Bombay, or 137 more than the preceding week. Since January 4, 5 Europeans have been attacked by the disease in Bombay. The deaths from this cause in Bengal for the week ending February 9, numbered 2491, the greatest mortality being at Patna, i. e., 1408. In Calcutta there were 129 deaths during this period, and on February 10, 11, 12, 13 and 14, they numbered respectively 17, 16, 30, 35 and 30. The deaths in Mysore, which is the only province in India in which the plague is not increasing, numbered 226 for the week ending February 9. In Mauritius 16 new cases occured during the week ending February 21, with 13 deaths. Cablegrams announce that 3 cases were reported in Singapore on February 22 and 24, and 1 case at Port Adelaide, Australia, on a transport which arrived from Cape Town, March 2. Reports also indicate 2 cases near Brisbane, Australia. Cablegrams of March 14 announce that 4 cases of the disease among Europeans have been officially reported in Cape Town, S. A., and 8 more among colored people, with 37 deaths to that date. The outbreak of plague at Cape Town threatens to become serious. The government is taking from the corporation full control of the measures for combating the disease and is engaging a large number of inspectors and scavengers to cleanse every quarter of the city and destroy rats and vermin. Professor Simpson, the plague expert; Dr. Gregory, the government health officer, and Dr. Fuller, the city health officer, will act as joint advisers in the treatment of the outbreak. Systematic cleansing of all houses has been begun. The city has been divided into districts, each in charge of a doctor assisted by a sanitary staff. For the natives, a location is being prepared, to which they will be removed from their hovels, the latter being cleansed or destroyed.

LONDON.

The Royal Commission on Arsenical Poisoning.

Under the presidency of Lord Kelvin, the royal commission appointed to investigate the amount of recent exceptional sickness and death due to arsenical poisoning, the extent to which this was due to the presence of arsenic in beer or other articles of food or drinks, and how such poisoning can be prevented in the future, has commenced its sittings in London. Most of the evidence given up to the present has been previously reported in The Journal. Dr. Tattersall, medical officer of health of Salford, an important town with a population of 222,000, near Manchester, described the outbreak there. The facts are exactly parallel to those of the Manchester outbreak. In June, 1900, a great increase was observed in the number of cases of peripheral neuritis, and in November a still further increase. All the sufferers were beer drinkers and took from 1 to 16 pints of beer daily. Lead poisoning was suspected, but analysis of samples of beer taken from fourteen breweries were negative. Dr. Reynolds' discovery of arsenic in the beer of Manchester revealed the cause of the peripheral neuritis; 996 cases were reported, and there were 107 deaths, probably due to arsenical poisoning. The outbreak lasted from June to the end of November. Moderate drinkers took about half a grain of arsenic weekly; in some cases as much as 4 grains was taken.

Intestinal Sand.

At the Royal Medical and Chirurgical Society, Sir Dyce Duckworth and Dr. A. Garrod related a case of this condition, which has been rarely recorded in England as compared with the Continent. A married woman, aged 33, lived in healthy surroundings, save for the supply of water, which was hard and contained organic impurities. The family history showed a gouty stock. In January, 1900, the illness commenced with intractable diarrhea, accompanied by internal rumbling and purring noises, there being six or eight loose motions in each twenty-four hours. In February the patient took to her bed and was ordered an exclusively milk diet and lime-water. This lessened the diarrhea to three or four motions daily, sometimes attended with the passage of mucus. In March sand was discovered in the motions and it was found subsequently in all in which it was looked for. Early in May she was pallid and sparely nourished. On examining the abdomen the colon and sigmoid flexure were found empty, too readily palpable and apparently thickened. The right kidney was movable. The temperature occasionally rose to 100 F. The sand was reddish-brown, finely gritty, and much resembled a deposit of uric acid. The patient was confined to bed and kept on a milk diet. Salicylate of bismuth and bicarbonate were given and the diarrhea was checked and health improved. All vegetable food was withheld and digestion found to be much more comfortable without it, as it caused immediate distension. In November the patient was rather pallid, but had regained her weight and the bowel no longer appeared thickened, but the splenic flexure was tender. There was still looseness of the bowel, from two to four actions occurring daily, but no sand was passed.

This case presents some of the characteristics which have been described in the few instances of the disorder on record. But it is remarkable in the slightness of the pain. In most cases paroxysmal pains lasting several hours were a characteristic feature. When washed and dried in the air the gritty material passed with the motions had the appearance of fine sand. It was deep brown, with an admixture of pale particles. Under a low power of the microscope the granules were seen to be of a great variety of shapes; some were roughly oval, some oblong or rod-like, others irregular. Their color varied from yellow to brown. The air-dried sand was composed of water, 12.4; organic matter, 26.2, and inorganic, 61.3 per cent. Analysis showed that the inorganic matter was composed of CaO 54.9, P_2O_5 42.5, CO_2 2.2, and traces of Mg. and Fe.

Extensive Enterectomy.

Mr. A. E. Barker described the case of a feeble old woman, aged 76, admitted to the hospital. In 1870 she had undergone ovariotomy. For two years she had a large ventral hernia in the scar. On January 8 and 9 she had not felt well, and complained of some pain in the abdomen, but was not sick. On January 10 she was seized with severe pain in the abdomen and vomited. The hernial tumor was tender and more swollen than usual. No motion or flatus was passed. Mr. Barker opened the abdomen through the old scar, and about a pint of dirty, blood-stained fluid, with a fishy odor, gushed out. A loop of blackened small intestine. about three feet long, was found strangulated through the omentum. The gut had not entirely lost its luster, but was very foul and distended tightly with dark blood-stained fluid. Subperitoneal hemorrhages existed in several places and a few of the subperitoneal venules were thrombosed. The extremely foul and fishy odor of the gut determined Mr. Barker to remove it, as its recovery seemed hopeless. He therefore cut away 5½ feet of the bowel and anastomosed end-to-end as rapidly as possible. This part of the operation occupied forty-four minutes, the whole of the operation sixty-three. During this twelve ounces of normal saline solution were injected subcutaneously. Recovery was uninterrupted.

Painless Pyonephrosis Without Fever.

At the Medical Society of London, Mr. Alban Doran brought forward this case because, though painless calculous pyonephrosis is not unknown, surgeons are often induced, in a case of enlarged kidney, to exclude calculous pyonephrosis on the ground that the disease must always be painful. A woman, aged 38, had borne eight children, the youngest of whom was 5½ years. Her husband had been subject to stricture and cystitis. For a few months she had a purulent vaginal discharge. For a year she had noticed a swelling in the left side; it ached when she put on her stays, but when undressed she was always comfortable. There was no history of rigors, fever, hematuria or renal colic. A large movable kidney lay in the right groin; it was not tender. The urine occasionally contained albumin. The kidney was exposed by Langenbeck's incision and easily extracted. It had become a cyst containing about a pint of "laudable pus," without a trace of tubercle. The lower calyces were blocked by a small rough calculus. The infection was probably gonococcic. The absence of fever was remarkable. The kidney was converted into a bag of pus and yet the patient appeared in excellent health.

Correspondence.

The Physician and Commercialism.

Chicago, March 1, 1901.

To the Editor:—The recent commendable action of the Chicago Medical Society (The Journal, February 2, p. 331) in so emphatically taking a stand against the much discussed division of specialist's fees, is to be, the writer trusts, only the first move toward a more thorough and rigid ethical introspection. For it is only by such decisive action that every member of the profession can be made to appreciate how insidious and dangerous has been the progress of commercialism in medicine.

Recent stock in a mineral springs company has been offered to—and, indeed, purchased by—some of our leading physicians at a very advantageous price. It being explained to the physician visited, by the solicitor for the company, that the water is practically pure—there is no doubt the spring furnishes good water—that he can without hesitation recommend it to his patients, that the sale of the water is to depend upon physicians' and druggists' recommendations entirely, there being a definite profit on every gallon sold, he (the physician) can by each and every prescription increase the earnings on the stock he holds; indeed, from a businessman's standpoint the proposition is a very attractive one, and it is being conducted upon such conservative lines that very few physicians who have subscribed for stock realize how questionable is the transaction from the ethical standpoint. To all questions there are two sides, and this is not an exception. Wherever pure water is difficult to obtain it can be seen that the patient would be better served by physicians combining, and, if necessary, purchasing a pure spring and recommending its waters, but in such a case it would be a satisfaction to the physician to explain to his patients his connection with the company and his reasons for such connection; the patient's confidence in the physician would thus be strengthened and not weakened, and the medical adviser would thus guard his patient from possible water-supply impositions and be in no danger of embarrassments consequent upon an unexpected disclosure to the patient of his (the physician's) connection with a water company whose products he had been so earnest in recommending. Should physicians then, as household consultants, take a financial interest in any drug, mineral spring, instrument, appliance, or institution, when such an interest might in any way prostitute our best judgment? Why not remember our patient's rights? He looks to us for untrammeled judgment; has he not then a right to expect that we receive no further financial return than what we charge him for our services? If it becomes necessary for physicians to take a financial interest in a water or in any other supply company, to insure better service, let them combine and control such supply, that they may be able to dictate absolutely the policy of such a company, and not be, as in the cases cited, merely nominal stockholders. The public and clientage would thus, through the printed matter of such an organization, be informed as to who are actual owners, and participants in the profits of such a company.

Diabetes Mellitus in Hebrews.

Philadelphia, March 3, 1901.

To the Editor:—In your editorial[1] on "Diabetes Mellitus" you mention Dr. von Noorden's communication on this subject, and with regard to etiology, special emphasis is given to the predisposition of the Jews to diabetes. I certainly can not agree with this view, at least not to the full extent of the general opinion. It is true, Jews are proportionately more disposed to diabetes than other people, but this fact has nothing to do with the race of Jews, and by the suggestion of the widespread prevalence of diabetes their dissemination and admixture with Indo-Germanic blood is placed on a wrong premise.

It is a well-known fact that nervousness, overstrain, overwork and cares are factors in the etiology of diabetes. If we look on the statistics of diabetes, we find that merchants, bankers, etc., furnish the greater number of diabetics. If we consider this fact, we need not wonder that the Jewish race furnishes a relatively larger proporton of sufferers from this affection. Several years ago Dr. Krämer, of Frankfort-on-the-Main, published statistics of the City of Frankfort in regard to diabetes, and he came to the same conclusion to which Dr. von Noorden, of the same city, comes. No one conversant with the conditions of Frankfort can help knowing that this city quite particularly has a large population of Jewish merchants, bankers and businessmen in general, perhaps in a much greater proportion than any other city. At that time Dr. Ruff, of Carlsbad, Bohemia, the Mecca of diabetics, rejected the statistics of Dr. Krämer and on the basis of the number and occupation of the visitors to Carlsbad. Dr. Ruff states that the lists of the Carlsbad visitors are not in agreement with Dr. Krämer, and no doubt neither with Dr. von Noorden. Dr. Ruff mentions that even most of the women diabetics who come to Carlsbad are business women, who are burdened with the occupations which as a rule are rather consigned to men.

I do not know whether this discussion between Dr. Krämer and Dr. Ruff ever appeared in a medical journal, as at that time it appeared in the *Allgemeine Zeitung des Judenthums* (1895 or 1896). Yours respectfully,

Albert Bernheim, M.D.

"The Technique of Bloodless Work."

New York City, March 16, 1901.

To the Editor:—My attention has been called to a letter from Dr. J. N. McCormack, in The Journal for March 2, commenting on my article on bloodless work, in The Journal for February 9.

Dr. McCormack boils over with righteous wrath, and so far forgets the amenities of warfare—which prohibit cruel or unusual punishments—as to call me, by implication, a "Christian Scientist." The connection seems a trifle obscure. But I suppose he cast about in his mind for the worst name he could think of, and just naturally hit on that one.

As a matter of fact, there was no personal animus whatever back of my article, in which the treatment of Governor Goebel was mentioned. The journals, medical and lay, which touched by the action of aluminum on oxid of iron. Prof. A. Primrose and Dr. Coutts gave a demonstration of the filaria parasite. One was exhibited in the living state, the filaria sanguinis hominis nocturna. Demonstrations were also given in the laboratories on radiographic experiments, microtomy and bacteriology.

Healthy Baking-Powder.—A deputation of the baking-powder men waited on the central government last week. They were accompanied by Dr. Peter T. Austin, a New York chemist, while the Inland Revenue Department was advised by its analysts, Messrs. T. MacFarlane and A. McGill. In a bulletin issued some months ago, noted in The Journal at the time, the employment of alum in baking-powders was condemned as being injurious to health. The contentions of the deputation were that whenever alum is used in making baking-powder it is mixed with bicarbonate of soda and, during the process of baking, goes off in the form of carbonic acid gas, and the residue left is not injurious to health. While a prohibitory law might be justified in England, where they employ a crude alum, it does not maintain in Canada, where the product goes into the manufacture. The deputation was promised a consideration of the question.

FOREIGN.

Dr. Henry Jellett, ex-assistant master of Retunda Hospital, Dublin, has been appointed editor of the *Medical Press and Circular*, to succeed the late Dr. Archibald Hamilton Jacob.

Snake-bites, according to the last annual report of the Indian Government, caused 24,621 deaths in India last year. The mortality from this cause does not seem to diminish in spite of all efforts of the government.

Deaths Abroad.—The death of G. A. Nordlund, professor of anatomy at Upsala, is announced, and that of C. J. Rossander, professor of surgery at Stockholm; of O. von Heusinger, professor of legal medicine and pediatrics at Marburg, and of J. Homan, assistant superintendent of the Kiel Institute of Hygiene.

Death of the Editor of "Vratch."—Prof. V. Manassein, who founded the leading Russian medical weekly, *Vratch*, twenty-one years ago, and has been its editor since, died at St. Petersburg, February 26, of apoplexy. He was in his sixty-first year. He served as professor of therapeutics and internal medicine for twenty-five years, and has published a number of important works.

Progress of the Plague.—According to the *British Medical Journal* of March 9, deaths from plague, for all India, for the week preceding February 9 numbered 4377, as compared with 3415 the previous week. For the week ending February 12, 923 died of plague in the City of Bombay, or 137 more than the preceding week. Since January 4, 5 Europeans have been attacked by the disease in Bombay. The deaths from this cause in Bengal for the week ending February 9, numbered 2491, the greatest mortality being at Patna, i. e., 1408. In Calcutta there were 129 deaths during this period, and on February 10, 11, 12, 13 and 14, they numbered respectively 17, 16, 30, 35 and 30. The deaths in Mysore, which is the only province in India in which the plague is not increasing, numbered 226 for the week ending February 9. In Mauritius 16 new cases occured during the week ending February 21, with 13 deaths. Cablegrams announce that 3 cases were reported in Singapore on February 22 and 24, and 1 case at Port Adelaide, Australia, on a transport which arrived from Cape Town, March 2. Reports also indicate 2 cases near Brisbane, Australia. Cablegrams of March 14 announce that 4 cases of the disease among Europeans have been officially reported in Cape Town, S. A., and 8 more among colored people, with 37 deaths to that date. The outbreak of plague at Cape Town threatens to become serious. The government is taking from the corporation full control of the measures for combating the disease and is engaging a large number of inspectors and scavengers to cleanse every quarter of the city and destroy rats and vermin. Professor Simpson, the plague expert; Dr. Gregory, the government health officer, and Dr. Fuller, the city health officer, will act as joint advisers in the treatment of the outbreak. Systematic cleansing of all houses has been begun. The city has been divided into districts, each in charge of a doctor assisted by a sanitary staff. For the natives, a location is being prepared, to which they will be removed from their hovels, the latter being cleansed or destroyed.

LONDON.

The Royal Commission on Arsenical Poisoning.

Under the presidency of Lord Kelvin, the royal commission appointed to investigate the amount of recent exceptional sickness and death due to arsenical poisoning, the extent to which this was due to the presence of arsenic in beer or other articles of food or drinks, and how such poisoning can be prevented in the future, has commenced its sittings in London. Most of the evidence given up to the present has been previously reported in The Journal. Dr. Tattersall, medical officer of health of Salford, an important town with a population of 222,000, near Manchester, described the outbreak there. The facts are exactly parallel to those of the Manchester outbreak. In June, 1900, a great increase was observed in the number of cases of peripheral neuritis, and in November a still further increase. All the sufferers were beer drinkers and took from 1 to 16 pints of beer daily. Lead poisoning was suspected, but analysis of samples of beer taken from fourteen breweries were negative. Dr. Reynolds' discovery of arsenic in the beer of Manchester revealed the cause of the peripheral neuritis; 996 cases were reported, and there were 107 deaths, probably due to arsenical poisoning. The outbreak lasted from June to the end of November. Moderate drinkers took about half a grain of arsenic weekly; in some cases as much as 4 grains was taken.

Intestinal Sand.

At the Royal Medical and Chirurgical Society, Sir Dyce Duckworth and Dr. A. Garrod related a case of this condition, which has been rarely recorded in England as compared with the Continent. A married woman, aged 33, lived in healthy surroundings, save for the supply of water, which was hard and contained organic impurities. The family history showed a gouty stock. In January, 1900, the illness commenced with intractable diarrhea, accompanied by internal rumbling and purring noises, there being six or eight loose motions in each twenty-four hours. In February the patient took to her bed and was ordered an exclusively milk diet and lime-water. This lessened the diarrhea to three or four motions daily, sometimes attended with the passage of mucus. In March sand was discovered in the motions and it was found subsequently in all in which it was looked for. Early in May she was pallid and sparely nourished. On examining the abdomen the colon and sigmoid flexure were found empty, too readily palpable and apparently thickened. The right kidney was movable. The temperature occasionally rose to 100 F. The sand was reddish-brown, finely gritty, and much resembled a deposit of uric acid. The patient was confined to bed and kept on a milk diet. Salicylate of bismuth and bicarbonate were given and the diarrhea was checked and health improved. All vegetable food was withheld and digestion found to be much more comfortable without it, as it caused immediate distension. In November the patient was rather pallid, but had regained her weight and the bowel no longer appeared thickened, but the splenic flexure was tender. There was still looseness of the bowel, from two to four actions occurring daily, but no sand was passed.

This case presents some of the characteristics which have been described in the few instances of the disorder on record. But it is remarkable in the slightness of the pain. In most cases paroxysmal pains lasting several hours were a characteristic feature. When washed and dried in the air the gritty material passed with the motions had the appearance of fine sand. It was deep brown, with an admixture of pale particles. Under a low power of the microscope the granules were seen to be of a great variety of shapes; some were roughly oval, some oblong or rod-like, others irregular. Their color varied from yellow to brown. The air-dried sand was composed of water, 12.4; organic matter, 26.2, and inorganic, 61.3 per cent. Analysis showed that the inorganic matter was composed of CaO 54.9, P_2O_5 42.5, CO_2 2.2, and traces of Mg. and Fe.

Extensive Enterectomy.

Mr. A. E. Barker described the case of a feeble old woman, aged 76, admitted to the hospital. In 1870 she had undergone ovariotomy. For two years she had a large ventral hernia in the scar. On January 8 and 9 she had not felt well, and complained of some pain in the abdomen, but was not sick. On January 10 she was seized with severe pain in the abdomen and vomited. The hernial tumor was tender and more swollen than usual. No motion or flatus was passed. Mr. Barker opened the abdomen through the old scar, and about a pint of dirty, blood-stained fluid, with a fishy odor, gushed out. A loop of blackened small intestine, about three feet long, was found strangulated through the omentum. The gut had not entirely lost its luster, but was very foul and distended tightly with dark blood-stained fluid. Subperitoneal hemorrhages existed in several places and a few of the subperitoneal venules were thrombosed. The extremely foul and fishy odor of the gut determined Mr. Barker to remove it, as its recovery seemed hopeless. He therefore cut away 5½ feet of the bowel and anastomosed end-to-end as rapidly as possible .This part of the operation occupied forty-four minutes, the whole of the operation sixty-three. During this twelve ounces of normal saline solution were injected subcutaneously. Recovery was uninterrupted.

Painless Pyonephrosis Without Fever.

At the Medical Society of London, Mr. Alban Doran brought forward this case because, though painless calculous pyonephrosis is not unknown, surgeons are often induced, in a case of enlarged kidney, to exclude calculous pyonephrosis on the ground that the disease must always be painful. A woman, aged 38, had borne eight children, the youngest of whom was 5½ years. Her husband had been subject to stricture and cystitis. For a few months she had a purulent vaginal discharge. For a year she had noticed a swelling in the left side; it ached when she put on her stays, but when undressed she was always comfortable. There was no history of rigors, fever, hematuria or renal colic. A large movable kidney lay in the right groin; it was not tender. The urine occasionally contained albumin. The kidney was exposed by Langenbeck's incision and easily extracted. It had become a cyst containing about a pint of "laudable pus," without a trace of tubercle. The lower calyces were blocked by a small rough calculus. The infection was probably gonococcic. The absence of fever was remarkable. The kidney was converted into a bag of pus and yet the patient appeared in excellent health.

Correspondence.

The Physician and Commercialism.

Chicago, March 1, 1901.

To the Editor:—The recent commendable action of the Chicago Medical Society (The Journal, February 2, p. 331) in so emphatically taking a stand against the much discussed division of specialist's fees, is to be, the writer trusts, only the first move toward a more thorough and rigid ethical introspection. For it is only by such decisive action that every member of the profession can be made to appreciate how insidious and dangerous has been the progress of commercialism in medicine.

Recent stock in a mineral springs company has been offered to—and, indeed, purchased by—some of our leading physicians at a very advantageous price. It being explained to the physician visited, by the solicitor for the company, that the water is practically pure—there is no doubt the spring furnishes good water—that he can without hesitation recommend it to his patients, that the sale of the water is to depend upon physicians' and druggists' recommendations entirely, there being a definite profit on every gallon sold, he (the physician) can by each and every prescription increase the earnings on the stock he holds; indeed, from a businessman's standpoint the proposition is a very attractive one, and it is being conducted upon such conservative lines that very few physicians who have subscribed for stock realize how questionable is the transaction from the ethical standpoint. To all questions there are two sides, and this is not an exception. Wherever pure water is difficult to obtain it can be seen that the patient would be better served by physicians combining, and, if necessary, purchasing a pure spring and recommending its waters, but in such a case it would be a satisfaction to the physician to explain to his patients his connection with the company and his reasons for such connection; the patient's confidence in the physician would thus be strengthened and not weakened, and the medical adviser would thus guard his patient from possible water-supply impositions and be in no danger of embarrassments consequent upon an unexpected disclosure to the patient of his (the physician's) connection with a water company whose products he had been so earnest in recommending. Should physicians then, as household consultants, take a financial interest in any drug, mineral spring, instrument, appliance, or institution, when such an interest might in any way prostitute our best judgment? Why not remember our patient's rights? He looks to us for untrammeled judgment; has he not then a right to expect that we receive no further financial return than what we charge him for our services? If it becomes necessary for physicians to take a financial interest in a water or in any other supply company, to insure better service, let them combine and control such supply, that they may be able to dictate absolutely the policy of such a company, and not be, as in the cases cited, merely nominal stockholders. The public and clientage would thus, through the printed matter of such an organization, be informed as to who are actual owners, and participants in the profits of such a company.

Diabetes Mellitus in Hebrews.

Philadelphia, March 3, 1901.

To the Editor:—In your editorial[1] on "Diabetes Mellitus" you mention Dr. von Noorden's communication on this subject, and with regard to etiology, special emphasis is given to the predisposition of the Jews to diabetes. I certainly can not agree with this view, at least not to the full extent of the general opinion. It is true, Jews are proportionately more disposed to diabetes than other people, but this fact has nothing to do with the race of Jews, and by the suggestion of the widespread prevalence of diabetes their dissemination and admixture with Indo-Germanic blood is placed on a wrong premise.

It is a well-known fact that nervousness, overstrain, overwork and cares are factors in the etiology of diabetes. If we look on the statistics of diabetes, we find that merchants, bankers, etc., furnish the greater number of diabetics. If we consider this fact, we need not wonder that the Jewish race furnishes a relatively larger proporton of sufferers from this affection. Several years ago Dr. Krämer, of Frankfort-on-the-Main, published statistics of the City of Frankfort in regard to diabetes, and he came to the same conclusion to which Dr. von Noorden, of the same city, comes. No one conversant with the conditions of Frankfort can help knowing that this city quite particularly has a large population of Jewish merchants, bankers and businessmen in general, perhaps in a much greater proportion than any other city. At that time Dr. Ruff, of Carlsbad, Bohemia, the Mecca of diabetics, rejected the statistics of Dr. Krämer and on the basis of the number and occupation of the visitors to Carlsbad. Dr. Ruff states that the lists of the Carlsbad visitors are not in agreement with Dr. Krämer, and no doubt neither with Dr. von Noorden. Dr. Ruff mentions that even most of the women diabetics who come to Carlsbad are business women, who are burdened with the occupations which as a rule are rather consigned to men.

I do not know whether this discussion between Dr. Krämer and Dr. Ruff ever appeared in a medical journal, as at that time it appeared in the *Allgemeine Zeitung des Judenthums* (1895 or 1896). Yours respectfully,

Albert Bernheim, M.D.

"The Technique of Bloodless Work."

New York City, March 16, 1901.

To the Editor:—My attention has been called to a letter from Dr. J. N. McCormack, in The Journal for March 2, commenting on my article on bloodless work, in The Journal for February 9.

Dr. McCormack boils over with righteous wrath, and so far forgets the amenities of warfare—which prohibit cruel or unusual punishments—as to call me, by implication, a "Christian Scientist." The connection seems a trifle obscure. But I suppose he cast about in his mind for the worst name he could think of, and just naturally hit on that one.

As a matter of fact, there was no personal animus whatever back of my article, in which the treatment of Governor Goebel was mentioned. The journals, medical and lay, which touched upon the matter in a paragraph or so, stated that he had been bled to control inward bleeding; but the physician's name did not appear. Consequently I had no means of inquiring directly. I presume that there are many other doctors besides myself who supposed the statements true, as they went uncontradicted.

---

[1] Journal A. M. A., March 2.

So much in explanation, and I am taking the first occasion after seeing Dr. McCormack's letter to withdraw my statement which, though not wilfully, has done him such injustice. Indeed, the actual treatment as he explains it could not be improved upon. It was wise and followed the most modern surgical standards. The use of hot, intravenous saline infusion so promptly was exactly the right thing done at the right time. I can but express surprise at a report becoming spread abroad, therefore, so at absolute variance with the facts as that which reached physicians here.

Dr. McCormack may rest assured that when I reprint my article for distribution, the Goebel reference will be wholly omitted; and I beg once more to assure him of my regrets.

Respectfully, Robert H. M. Dawbarn, M.D.

Arsenic in Pernicious Anemia and Leucocythemia.

Baltimore, Md., March 18, 1901.

To the Editor:—In The Journal of March 16, page 756, the following words appear—a part of a summary of some remarks by me before the Johns Hopkins Hospital Medical Society: "He has been astonished to hear the value of arsenic in pernicious anemia and leucocythemia questioned recently by a distinguished Boston clinician. There is positive evidence of its usefulness in these conditions."

I regret to say that this report of my remarks is somewhat erroneous. I referred, in an informal discussion, to Dr. Cabot's interesting remarks before the Association of American Physicians, last summer (Pernicious Anemia: A Study of 110 Cases. Transactions of the Association of American Physicians, 1900, xv, 334), and did express surprise that the author should regard arsenic of so little value in these cases, stating that it was my impression that in some instances it was of material benefit. I was far from stating, nor do I believe that the value of arsenic is by any means *positively proven.* And I am not aware that Dr. Cabot has questioned the value of arsenic in leukemia. Yours sincerely, W. S. Thayer, M. D.

The Determination of Sex.

Canton, Ohio, March, 9, 1901.

To the Editor:—Since you have considered it of sufficient importance to give editorial space to an article on the above subject, it may be of interest to know of a case where, for extrauterine pregnancy, it was necessary, in the laparotomy done for relief, to remove the left Fallopian tube and ovary. This woman, with a right ovary intact and a left ovary removed, has since given birth to two children, with an interval of several years between births. The first child was a female, the second a male. One would think that in this day there would be a sufficient number of mono-ovarian women giving birth to children, for one wishing to lay down a scientific theory, based on the hypothesis of ovarian determination of sex, to have led to an investigation of that phase of the subject for facts. Very truly, Edward P. Morrow, M.D.

Medico-Sociologic Data Wanted.

Atlanta, Ga., March 1.

To the Editor:—The sociological committee of the Tri-State Medical Society of Alabama, Georgia, and Tennessee desires information relative to any and all states that have enacted laws regulating marriage of criminals, insane, epileptics, tuberculous or those suffering with venereal disease. It also desires information of any legal enactments or literature on the subject of rendering habitual criminals sterile. Any information along this line, from any of your readers, will be greatly appreciated and gladly received. R. R. Kime, Chairman.

308 and 310 Eng.-Amer. Building.

Book Notices.

The Medical Examination for Life Insurance, and its Associated Clinical Methods, with Chapters on the Insurance of Substandard Lives and Accident Insurance. By Charles Lyman Greene, M.D., St. Paul, Minn., Clinical Professor of Medicine and Physical Diagnosis in the University of Minnesota. With 99 Illustrations. Cloth. Pp. 426. Price $4.00. Philadelphia: P. Blakiston's Son & Co. 1900.

Dr. Greene's treatise on medical examinations for life insurance is by far the most complete work on the subject extant. He states that the reason for the existence of this book is the introduction into medical schools of courses of lectures dealing especially with the medical aspect of life insurance. The work is, however, of equal if not greater value to the medical examiner, who has heretofore had relatively little to guide him, with the exception of the somewhat antiquated treatises up to this time obtainable and the exceedingly brief instructions issued to medical examiners by the respective insurance companies. The most valuable section is that which deals with the conventional questions found on examination blanks, their proper analysis and answers. It is gratifying to note that the author has obtained permission to use and insert the Nylic standard table of heights and weights. The influence of family history in modifying the value of risks is fully considered, as is also the effect of occupation on longevity and the incidence of disease. The section on examination of the chest is very well presented and excellently illustrated. One of the vexed questions that confront the examiner is that of the significance of a pulse which does not vary whether the applicant is sitting or standing, and this question does not seem to be considered by the author. The discussion of the examination of the urine is concise and excellent, but nothing authoritative is stated regarding the important points of the bearing of occasional albuminuria, the so-called physiologic albuminuria, occasional glycosuria, and digestive glycosuria on the value of risks. The author merely quotes, without especial comment, the already-published dicta of certain medical directors regarding these matters. A unique chapter is that on the insurance of substandard lives—a class of risks which nowadays is attracting a great deal of attention among the so-called "old-line" companies. The last two chapters of the volume are devoted to fraud and to accident insurance. The book, taken as a whole, is commendable and marks a great advance in the literature of this important subject.

The Care of the Consumptive. A Consideration of the Scientific Use of Natural Therapeutic Agencies in the Prevention and Cure of Consumption; Together with a Chapter on Colorado as a Resort for Invalids. By Charles Fox Gardiner, M.D., Non-resident Fellow of the New York Academy of Medicine. Cloth. Pp. 182. Price, $1.25. New York and London: G. P. Putnam's Sons. 1900.

The author states that his object is to give in a clear and practical way the rules which should govern the consumptive in the use of fresh air, sunlight, food, rest and exercise, so that these natural beneficial agencies shall be applied to the best advantage. These are, as he maintains, still the best, most convenient and durable of any curative methods applied in the disease. The book is brief in its treatment of the subject, but seems to be amply full for its purpose, while the advice on the whole is excellent. The latter third of the work is given to a description of the climate of Colorado and its advantages, in which it is shown how many consumptives can make their residence there and obtain perfect health. The author believes that the nervous system does not suffer from high altitudes and the typical nervous invalid is not necessarily a contraindication to resort to that section. It is interesting to note how writers of elaborate works on consumption are more conservative than many who merely repeat the prevalent views. This one apparently does not favor the extreme theories of contagion that are held. An impaired vital activity giving the germs, so universally diffused, a chance is, he holds, the more important factor, and he uses as his argument the experience of Colorado Springs, where the danger from contagion should be the greatest, if the views held by many were correct.

The History of Medicine in the United States. A Collection of Facts and Documents Relating to the History of Medical Science in This Country, from the Earliest English Colonization to the Year 1800. With a Supplemental Chapter on the Discovery of Anesthesia. By Francis Randolph Packard, M.D. Illustrated. Cloth. Pp. 542. Price, $4.00 net. Philadelphia and London: J. B. Lippincott Company. 1901.

While there have been many "bits" of medical history published heretofore, some complete as they affected one colony, or one phase, this we believe is the first to appear thoroughly covering all the colonies and all that relates to the subject. The first chapter is general in its character, giving an insight into the conditions existing in the early days when the physician was a combination of preacher and doctor, if not a combination of half a dozen callings. This is the most interesting part of the book, at least to those who love the curious. The author has evidently ransacked every library and searched every book that could possibly throw light on those who founded the profession of medicine in the United States.

Much that is curious, as well as instructive in many ways, is recorded in this part. The following quaint ending to a manuscript on "Receipts to Cure Various Disorders," sent over from London in 1643, by a Dr. Ed. Stafford, is worth quoting: "*Nota bene.* No man can with a good conscience take a fee or a reward before ye partie receive benefit apparent; and then he is not to demand anything but what God shall putt into the head of the partie to give him. And he is not to refuse anything that shall be so given him, for it comes from God. A man is not to neglect that partie, to whom he hath once administered, but to visit him at least once a day, and to medle with no more than he can well attend. In so doing he shall discharge a good conscience before God and man." Certainly this is good advice. But the following notice, which appeared in the *Boston Evening Post and the General Advertiser*, November, 1781, would be more approved to-day: "The physicians of the town of Boston hereby inform the public, that, in consideration of the great fatigue and inevitable injury to their constitution, in the practice of midwifery, as well as the necessary interruption of the other branches of their profession, they shall, for the future, expect that in calls of this kind, the fee be immediately discharged."

Two chapters are taken up with a description of the epidemics which occurred previous to 1800. The sufferings of those early pioneers are graphically described and the sacrifices made by the physicians of that time, as told here, should make the commercially-inclined modern physician blush. Epidemics were common in those days, smallpox especially being often prevalent and generally terribly fatal. The account of the inoculation against this disease, and of the application of vaccination and the excellent results obtained, should be read by those who think they think that vaccination is not one of the greatest discoveries of the ages, and that it has not proved one of the greatest blessings that medical men have given to humanity.

An account of medical education before the formation of medical schools occupies one chapter, and in another is given a history of the early medical colleges. The medical profession in the War for Independence, the earliest hospitals, medical societies and medical legislation in the colonies are among the subjects thoroughly treated. A chapter is devoted to anesthesia, but why we can not imagine. The author has otherwise confined himself to events preceding the opening of the nineteenth century.

Too much praise can not be bestowed on this history of early medical history in this country. The author has not only given us a most complete account of all that pertains to medicine and medical men, but he has put it before the reader in such a manner as to make the reading of it a pleasure. The subjects are so classified and arranged that little is duplicated, something hard to avoid when it is considered that each colony, to a certain extent at least, has to be treated as an entirety. The whole subject is so exhaustively, logically and scientifically treated by Packard that his book will immediately become a standard work on the subject.

A Manual of Medicine. Edited by W. H. Allchin, M.D. (Lond.), F.R.C.P., F.R.S.E., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. I. General Diseases: Diseases Excited by Atmospheric Influences; the Infections. Vol. II. General Diseases continued: Diseases Caused by Parasites; Diseases Determined by Poisons Introduced into the Body; Primary Perversions of General Nutrition; Diseases of the Blood. Cloth. Pp. 441 and 380 respectively. Price, $2.00 per volume. New York: MacMillan Co. 1901.

This work, two volumes of which have already appeared, is a brief but in many respects satisfactory compendium of medical practice. It is more of a compendium in that it is a composite work, the subjects being treated by different authors, the names of many of whom carry weight in this country as well as in Great Britain. The general articles are largely by the editor, Dr. Allchin, but the special ones on different diseases are by many different writers. This volume satisfactorily covers the subject of general diseases in the main, though the articles are necessarily brief, in one or two cases unduly so. For example, pneumonia is a general infection, but is here treated only in its aspects as an epidemic disease, leaving out the general description and what the practitioner most desires to know. The second volume also deals with general diseases and is of the same general character.

Therapeutics: Its Principles and Practice. By Horatio C. Wood, M.D., LL.D. (Lafayette-Yale), Professor of Materia Medica and Therapeutics, and Clinical Professor of Diseases of the Nervous System, in the University of Pennsylvania. Eleventh Edition. Remodelled and in Greater Part Rewritten. By Horatio C. Wood and Horatio C. Wood, Jr., M.D., Demonstrator of Pharmacodynamics in the University of Pennsylvania. Cloth. Pp. 850. Price $5.00. Philadelphia and London: J. B. Lippincott Co. 1900.

Wood's Therapeutics has been so long before the medical public that its eleventh issue hardly requires an introduction. The author, however, states that while other editions have been chiefly improved by incorporation of new matter, in the present edition an effort has been made throughout to get a new view of the whole subject of therapeutics, presented in the most attractive form. The use of small type for minor descriptions and discussions, etc., is an advantage. Taking the references out of the body of the text and putting them in nonpareil at the end of the chapter is perhaps more satisfactory to many, but this is not as well as having them directly before the eye on the page in which they are made; this, however, is a minor matter. All new drugs of any value, according to medical experience, are included, though no work can keep up with the flood of products which are constantly being put out and recommended to the medical profession. The present edition will undoubtedly still hold its place among the standard textbooks on therapeutics.

The Year Book of the Nose, Throat, and Ear. The Nose and Throat, edited by G. P. Head, M.D., Professor of Laryngology and Rhinology in the Post-Graduate Medical School of Chicago. The Ear, edited by Albert H. Andrews, M.D., Professor of Otology in the Post-Graduate Medical School of Chicago. Cloth. Pp. 416. Price $2.00. Chicago: The Year-Book Publishers. 1901.

The previous volume of this year-book was so well received that the editors continued their work and give us this year a somewhat larger compilation of the literature on nose, throat and ear diseases than was given last year. The abstracts are well selected and cover the whole range of the ordinarily accessible literature. They notice the difficulties which every one must experience who is engaged in the work of culling out the essence of what has been written, and remark in their preface that many articles have been omitted on account of their being simply statements of accepted opinions written for the general practitioner, or in some cases that they touch upon so many points of such importance that abstracting is not possible. They are mentioned under proper headings so that those interested may readily refer to them. The two volumes that have appeared of this year-book make one hope that it will receive sufficient support to justify its continuance for years to come.

A Text-Book of Pharmacology and Therapeutics, or the action of Drugs in Health and Disease. By Arthur R. Cushny, M.A., M.D., Aberd., Professor of Materia Medica and Therapeutics in the University of Michigan. Second Edition, Revised and Enlarged. Illustrated with 47 Engravings. Cloth. Pp. 732. Price $3.75. Philadelphia and New York: Lea Brothers & Co. 1901.

The first edition of this work was exhausted in a little over a year and the present volume has been brought up to the latest advances in the subject, though not many changes, as the author remarks, have been found necessary. The work holds a position of its own among handbooks on therapeutics and its apparent success is well deserved.

Association News.

The Doctors' Special to St. Paul.

Louisville, Ky., March 15, 1901.

To the Editor:—The nearness of the next meeting of the Association in St. Paul suggests the necessity of plans being laid for attendance by the profession of the country, and consequently the selection of a route. The many advantages of traveling in large numbers to these meetings can be vouched for by those who have been fortunate enough to so travel to several meetings in the past.

As Louisville is one of the gateways for Chicago and St. Paul, arrangements have been made for special accommodations from this point, with special doctors' sleepers attached to the regular service of the Monon Route to Chicago and from that point by the Chicago & Northwestern Railroad to St. Paul. Close connections will be made at Louisville with the Southern and the Louisville & Nashville railways from points in the South, Atlanta, Birmingham, Nashville, Asheville, and Memphis. A day trip will be made between Louisville and Chicago, June 3, and a night trip from Chicago to St. Paul, arriving there in time for breakfast the first day of the meeting, June 4.

At this writing the rates for the St. Paul meeting have not been announced, but the undersigned will be pleased to answer queries as to the connections, time of arrival and departure of connecting lines, etc., and make sleeping-car reservations for those who wish to join the "Doctors' Special to the American Medical Association." Very truly yours,

111 West Kentucky Street. Henry E. Tuley, M.D.

Deaths and Obituaries.

John R. Page, M.D., University of Virginia, Charlottesville, 1850, died at that institution March 11, from acute Bright's disease, aged 71. He was chief surgeon in the confederate service, and was afterward a professor in the Louisiana Military Academy, and in the Washington Medical College of Baltimore. In 1873 he became a professor of agricultural chemistry and scientific farming in the University of Virginia. In 1887 he resigned the latter position and resumed the practice of his profession.

John A. Goldsberry, M.D., Rush Medical College, Chicago, 1857, who was struck by a train at West Union, Ind., February 25, died at Kingman, March 7, from his injuries. He was 65 years old. He served through the Civil War at Baton Rouge, La., and then practiced in Annapolis, later in Bloomingdale, Ind. He was a member of the Park County and Indiana State Medical societies, and of the American Medical Association.

Jason Walker, M.D., Medical School of Maine, Brunswick, 1865, a member of the Androscoggin County and Maine State Medical societies, and of the American Medical Association, and for more than thirty years a practitioner in Minot, Maine, died at his home in that place, from chronic bronchitis, March 7, aged 66.

Edward Bradley, M.D., University of Vermont, 1859, at which institution he was for a time demonstrator of anatomy, died at his home in New York City, aged 65 years. During the Civil War he was an acting assistant-surgeon. He was an active dispensary surgeon and in repute as a neurologist.

James Johnston, M.D., Starling Medical College, Columbus, Ohio, 1857, died suddenly from nephritic colic March 9, at his home in Gallipolis, Ohio, aged 67. He was assistant-surgeon, O. V. I., during the Civil War, and a prominent physician of southern Ohio.

John T. Black, M.D., College of Physicians and Surgeons, Baltimore, 1883, for several years physician at the steel works of the Carnegie company, Duquesne, Pa., died at his home in that place, March 10, from pneumonia, after an illness of three weeks, aged 53.

Thomas A. Fairbairn, M.D., Bellevue Hospital Medical College, New York, 1867, formerly of Detroit, Mich., but for the last thirteen years a resident of California, died in San Diego, Cal., from pneumonia following influenza, March 6, aged 71.

Ferdinand Bazan, M.D., Faculty of Medicine, Paris, France, 1873, formerly a well-known practitioner of San Francisco, and for fourteen years surgeon-in-chief of the French Hospital, died at Glion sur Montreux, Switzerland, March 6.

Henry C. McCoy, M.D., Northwestern University Medical School, Chicago, 1865, a pioneer physician of Algona, Iowa, where he had practiced for more than thirty years, died at his home in that place, from pneumonia, March 10, aged 62.

Caleb E. Martin, M.D., University of the Victoria College, Cobourg, Ont., 1856, of Toronto, died March 11, at Whatcom, Wash., where he had gone on account of ill health. He served as a surgeon under General Sheridan in the Civil War.

John B. McDonald, M.D., Harvard University Medical School, Boston, 1865, an early settler and practitioner of Dickinson, N. D., who moved, in 1896, to Spokane, Wash., died at his home in that city, March 3, aged 63.

Thomas Riley, M.D., University of Michigan, Ann Arbor, 1874, who practiced for many years at Adams, Mass., died from general paresis, after an illness of two years, at the Northampton Hospital, March 4, aged 58.

Robert H. Dodge, M.D., University of Georgetown, Washington, D. C., 1893, physician-in-charge of the Conrad Sanatorium, Relay Station, Md., died at his home in Bethesda, Md., after a short illness, March 11, aged 29.

Ashley N. Denton, M.D., Texas Medical College and Hospital, Galveston, 1866, died at his home in Austin, Texas, March 4. He was for several years superintendent of the state insane asylum at Austin.

Allan S. MacDonell, M.D., College of Physicians and Surgeons of Ontario, Toronto, 1882, died at Rat Portage, Ont., where he had practiced for several years, March 6, from pneumonia, aged 47.

Emory Hawkins Davis, M.D., University of Vermont, Burlington, 1872, died at his home in Plainfield, Conn., aged 56. He was a member of the State and Windham County medical societies.

Hiram Crounse, M.D., Castleton Medical College, Castleton, Vt., 1847, one of the oldest physicians of Albany County, New York, died at his home in Clarksville, March 1, aged 80.

Philip Du Bois Hoornbeck, M.D., Geneva Medical College, Geneva, N. Y., 1846, died recently at his home in Wawarsing, N. Y., where he had practiced for more than half a century.

Caleb Hale, M.D., University of Louisville, Ky., 1859, for more than forty years a practitioner in Daviess County, died at his home near Whitesville, Ky., March 7.

R. L. Mayfield, M.D., Barnes Medical College, St. Louis, died at Mayfield Sanatorium, Marble Hill, Mo., of which he was assistant superintendent, March 5.

Frederick M. Johnston, M.D., Detroit Medical College, 1897, a practitioner of Three Oaks, Mich., died from appendicitis, in a Detroit hospital, March 1.

John Sims, M.D., Medical College of Georgia, Augusta, 1855, prominent as a citizen, physician and legislator, died at his home in Leverett, Ga., March 4.

Jesse A. Hartson, M.D., College of Physicians and Surgeons, Baltimore, 1894, died at his home in Ava, N. Y., March 7, from pneumonia, aged 33.

John Sylcurk, M.D., University of Maryland, Baltimore, died from consumption, March 5, at the home of his parents in Frederick, Md., aged 25.

David S. Cook, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1855, died at his home in Wheatland, Iowa, suddenly, March 7, aged 76.

Thomas J. Patterson, M.D., University of Louisville, 1851, died at his home near Caney Spring, Tenn., March 3, after a lingering illness.

W. Eugene Martin, M.D., University of Louisville, 1894, died at McColl, Marlboro County, South Carolina, March 8, aged 25.

Martin J. Hutchens, M.D., University of Vermont, Burlington, 1862, died at his home in Redwood, N. Y., March 1, aged 75.

James H. Rogers, M.D., Jefferson, 1855, once a practitioner of Sag Harbor, N. Y., died in New York City, March 12, aged 71.

Sullivan B. Dorn, M.D., University of Buffalo, died in a hospital at Bradford, Pa., from pneumonia, March 6, aged 59.

Alonzo T. Smith, M.D., Geneva Medical College, died at his home in Syracuse, N. Y., March 8, from pneumonia, aged 80.

Sanford H. Sloan, M.D., Missouri Medical College, St. Louis, 1881, died from cerebral hemorrhage, March 10.

Paul von Seydewitz, M.D., University of Heidelberg, Germany, 1869, died in New Orleans, March 15, aged 74.

David O. Moore, M.D., health officer of Bloomington, Ill., died from chronic kidney disease, March 15, aged 68.

Miscellany.

The Vitality of the Bubonic Bacillus.—Professor Koch, of Berlin, reports upon 1400 cases of the bubonic plague, as seen in Bombay and other parts of India. He avers that the bacillus has but little vitality outside the bodies of animals, and adds that Haffkine's serum is endowed with undoubted protective qualities.

Cataract and Tetany.—Similarly to diabetic cataract, the lens may become clouded during the course of tetany. The cataract in this case is regular and does not resemble the ordinary variety. The *St. Petersburg Med. Woch.*, No. 4, mentions two cases, one a woman of 22, the other a man of 35. The tetany in the latter case had persisted eleven years; all the hair had fallen out, and there were frequent attacks of headache and diarrhea. The cataract ripened in each eye with a year's interval. Both were successfully removed.

Medical Advertising and the Lay Press.—Whenever we find a lay journal that governs itself by high ethical principles as regards certain medical questions in respect to which members of the lay press are generally and collectively sinners, it is a pleasure to note the fact. The following editorial extracts, therefore, from the *Cedar Rapids* (Iowa) *Gazette* are offered with commendation:

> It is possible that *The Gazette* has no business to refer to what other papers do in business matters, and yet it may be true that there are some questions, the calling attention to which might result in good. No reference is made or intended for any publication in particular, the simple idea being that newspapers in general should refuse to contaminate their columns with a lot of vile advertisements, some of them being filthy. It looks as if papers devoting so much space to such advertising are either hard up for clean advertising or else have no care as to how much filth they place before their readers. * * * There are the villainous references to female troubles, which no honorable or decent paper would print. Publications that name diseases and display them in great black type insult the sacredness of womanhood. There are a number of such advertisements and the more of them the greater the shame.
>
> Among the vile advertisements also are remedies for all sorts of private and venereal diseases, and it is only reasonable to suppose that it must "pay" the advertiser, and consequently it follows that some readers of such papers need the stuff.
>
> Certain kinds of pills are advertised that are intended for criminal purposes, and they lead to added crimes by making those immorally inclined believe that it will save them from trouble, when it gets them into it instead.
>
> No parent should permit papers containing such advertisements to be found in their homes.
>
> Bishops, clergymen, editors and others are either induced to permit the use of their names for notoriety, are paid for so doing, or their names are forged to all sorts of rotten advertisements.
>
> Reading notices concerning various nauseating matters are placed right between clean news items in order to be sure and attract attention. How do clean advertisers of clean goods like to see it? How much is their advertising worth in such papers? * * *

Antimosquito Experiences With Malaria.—Professor Fermi, of Sassari, Sardinia, states (*Gazz. degli. Osp.*, March 3) that 27 soldiers were placed in a dormitory in which 17 out of the 18 previous inmates had been taken with malarial fever. The room had been whitewashed and screened, and the new occupants were protected with gloves and hoods, but none took any quinin. None showed any trace of malarial infection during the month of the test, while 23 of the occupants of the next dormitory became affected with malaria. Another building had the reputation of being extremely malarial, but after the windows were screened none of the new inmates became affected. The third experiment was with a party of 25, and another of 32 soldiers who marched and camped out along the most malarial portion of the shore. The only protections in this case were gloves and hoods worn by the members of the expeditions. None showed any signs of infection, but a mocking spectator who accompanied them on horseback, unprotected from mosquitoes, exhibited symptoms of the quotidian type in less than a week. Another party of 27 members slept in the open air for ten nights, with no symptoms of infection except in the case of one youth who was incommoded by the hood and occasionally pulled it off.

Does Vaccination Prevent Smallpox?—The *Cincinnati Lancet-Clinic* of March 16 prints a letter recently sent to Dr. E. Stuver, in which the writer says: "The only objection I can possibly put forth against your deductions is that you believe that *vaccination prevents smallpox.* On this rock *you have foundered*, as no such fact can be sustained by science, experience or common sense. Take away sanitary science and all infectious diseases will be rampant in the land." In Dr. Stuver's comprehensive answer he defines "sanitary science" as "the science and art of promoting healthy development, maintaining the mature organism in a healthy condition of normal functional activity, preventing the invasion of diseases and stamping them out as soon as possible when they have arisen," and says: "1. No historical fact is better established than that, before the discovery of vaccination, smallpox was one of the most fatal and dreaded scourges which afflicted humanity. It swept over Europe, leaving death, devastation and terror in its path; indeed, so widespread was the disease that, as the historian Macaulay informs us, it was a rare thing at one time to find a person in London not disfigured or marked by that dread disease. To-day smallpox is one of the rarest diseases, and scarcely figures in mortality statistics. You say this reduction has been brought about by 'sanitary science,' whatever you may mean by that, because if vaccination is *not* one of the most effective sanitary measures the world has ever seen, I do not know what you would designate it. 2. The English, German, French or American soldiers who have been properly vaccinated can be brought face to face with smallpox in the unhealthy tropics, in places reeking with filth, and all sanitary conditions much worse than the London described by Macaulay, and these soldiers are almost absolutely immune against the disease. Why is this? Does the sanitation of the countries from which they come, thousands of miles away, protect these men, in the midst of unnatural and health-destroying environments, against a disease which is destroying thousands of *acclimated natives?* 3. Why is it, if vaccination does not prevent smallpox, that epidemics of the disease can be brought under control by this means, and *by this means* *alone?* Else why should the bitter opponents of the measure resort to it for safety in the face of danger, as they did in the epidemic in England a few years ago? 4. I have often thought that through generations of vaccination a vital resistance has been created, and a partial immunity established, so that when smallpox attacks even those who have not been personally vaccinated, owing to the mitigating influence of vaccination in their ancestors, the disease assumes a milder form. 5. As every observer knows, smallpox epidemics nearly always follow comparatively long periods of immunity from the disease, when the people have become careless, neglected to be vaccinated, and there are large numbers susceptible to the disease. 6. But the antivaccinationist holds up his hands in horror, and with a scared look and bated breath calls our attention to the horrible diseases and occasional deaths caused by vaccination. Admitted that syphilis and other diseases have been conveyed, and blood-poisoning caused in rare instances (and they are exceedingly rare, compared with the whole number of vaccinations), still the evil is but a tiny trickling rill alongside the great river of beneficence which this grand discovery has brought to soothe and save suffering humanity. With approved modern methods for the production and marketing of bovine vaccin virus, and proper antiseptic or aseptic precautions in making the vaccinations, even these infrequent accidents ought to be almost entirely prevented. It would be just as fair to formulate an opinion as to the propriety and justifiability of abdominal operations and major surgical operations from their pre-antiseptic and pre-aseptic mortalities as it is to condemn vaccination for accidents and dangers that attended the use of infected virus and careless methods of performing the operation years ago, rather than to judge it by the results following the use of pure bovine virus and aseptic operating of the present time. 7. Then, too, a method which has passed through the ordeal of more than a hundred years of the closest investigation and most searching criticism, which has received the unqualified approval and support of nearly all scientific physicians in the whole civilized world, which has lifted the dark cloud of terror which paralyzed humanity so that the great majority of people have come to regard the once dread disease as an insignificant danger; when, I say, any preventive measure has accomplished such results as these, he is, indeed, a bold man who will advocate its discontinuance, unless he has something better to offer in its place. 8. I have often thought that, with the great benefits and small dangers of vaccination so generally recognized, and its benefits established on such a firm foundation, it was largely a matter of supererogation to resort to such severe measures in warding off smallpox. The persons who will not protect themselves against the disease do not have 'common sense' enough to enjoy good health, and should be left to their fate."

Societies.

COMING MEETINGS.

Tri-State Medical Society of Iowa, Illinois and Missouri, Keokuk, Ia., April 2-3, 1901.

Medical Association of the District of Columbia, Washington, D. C., April 2, 1901.

Tennessee State Medical Society, Nashville, April 9-11, 1901.

Florida Medical Association, Jacksonville, April 10, 1901.

Western Ophthalmological and Otolaryngological Association, Cincinnati, Ohio, April 11-12, 1901.

Medical Association of the State of Alabama, Selma, April 16, 1901.

Medical Society of the State of California, Sacramento, April 16-18, 1901.

South Carolina Medical Association, Florence, April 17, 1901.

Medical Association of Georgia, Augusta, April 17, 1901.

Louisiana State Medical Society New Orleans, April 18-20, 1901.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 23-26, 1901.

Texas State Medical Association, Galveston, April 23, 1901.

American Association of Genito-Urinary Surgeons, Old Point Comfort, April 30, 1901.

Association of American Physicians, Washington, D. C., April 0, 1901.

French Congress of Ophthalmology.—This congress is to convene at Paris, May 6. The subject announced for discussion is "The Value of Iridectomy in Glaucoma."

Carbondale (Pa.) Medical Society.—At the annual meeting of this society, held March 4, Dr. William W. Fletcher was elected president, and Dr. Sumner T. Davis, Jermyn, vice-president.

Union Medical Society of Northern Michigan.—This society announces its first quarterly meeting of the twentieth century, to be held at Greenville, April 9. Dr. Horace L. Bower, Greenville, is secretary.

Medical Society of the State of Tennessee.—The sixty-eighth annual session of this society will be held at Nashville, April 9, 10 and 11. Dr. William D. Haggard, Jr., is secretary, and Dr. Deering J. Roberts, chairman of the committee on arrangements.

Henderson County (Ill.) Medical Society.—This society was reorganized early this month, at Oquawka, and Dr. Isaac F. Harter, Longhurst, elected president; Dr. Coleman J. Eads, Oquawka, vice-president, and Dr. William D. Henderson, Biggsville, secretary and treasurer.

Lamar County (Ala.) Medical Society.—The annual meeting of this society was held at Vernon, March 4, and the following officers elected: Dr. Berry E. Turner, Richards, president; Dr. William L. Morton, Vernon, vice-president, and Dr. Judge C. Buckelow, Sulligent, secretary.

St. Clair County (Ill.) Medical Society.—The annual meeting of this society was held in Belleville, March 8, and the following officers elected: Dr. Julius Kohl, Belleville, president; Dr. James O. DeCourcy, East St. Louis, vice-president; Dr. Buenavandura H. Portuondo, Belleville, recording secretary; Dr. Adolph E. Hansing, East St. Louis, corresponding secretary, and Dr. Adolph Schlernitzauer, Millstadt, treasurer.

Rhode Island Medical Society.—A meeting of this society was held at Providence, March 7, at which the election of officers for the year following the next annual meeting took place: Dr. George F. Keene, Howard, president; Drs. William R. White, Providence, and Christopher F. Barker, Newport, vice-presidents; Dr. Frank L. Day, Providence, recording secretary; Dr. Herbert Terry, Providence, corresponding secretary and Dr. Frederick T. Rogers, Providence, treasurer.

Berlin Society of Internal Medicine.—This society celebrated its twentieth anniversary February 18, with much ceremony and a banquet. Von Leyden was made honorary president, as the society in a large measure owed its inception to his efforts. Honorary membership was also conferred on Baccelli, Nothnagel and von Behring. E. Roux, of Paris, Erb, Ehrlich, Weigert, Babes of Bucharest, and Hassimoto of Tokio, were appointed to be corresponding members.

ST. LOUIS MEDICAL SOCIETY OF MISSOURI.

Meeting held February 16.

Dr. L. E. Newman, president.

Carcinoma of the Prostate.

Dr. L. E. Newman submitted a specimen of this. The patient, a man of 49, was operated on May 12, 1900, a suprapubic cystotomy being done to relieve an intense cystitis and for diagnosing the prostatic trouble, which was believed to be carcinoma. It was impossible to remove the prostate, so the bladder was simply drained. The patient did well for seven months, but died in coma recently, having had cerebral symptoms for the last three weeks. Death was probably due to metastatic carcinoma of the brain, but this was not verified. The kidney contained three or four concretions and its artery was unusually large. The bladder at the time of operation was greatly thickened and roughened, so much so that it resembled the interior of a heart. After the seven months' drainage, it looked fairly healthy. When the patient was placed on the table he was deeply septic, the temperature being 103 F. His weight at the time of his death had fallen from 230 to 150 pounds. There were no kidney symptoms, unless the coma was one. The pain in the rectum was frightful and interfered with sleep. The prostatic growth he believed to be cancerous, because of its consistency and the involvement of surrounding structures.

Veratrum Viride: Its Undeserved Neglect.

Dr. E. W. Saunders read a paper on this topic. He considered its historical side, then its physiologic action. He finds it by far the safest motor depressant, as it has no detrimental effect on the blood and no effect on the ameboid movements of the white blood-corpuscles. Neither has it any harmful effect on those processes which ultimately destroy the invading micro-organisms in acute infectious diseases. Its depressant activity on the motor cells in the anterior cornua of the spinal cord indicates its use in puerperal eclampsia, in which he considers it the safest drug we can employ. During the eclamptic seizure he administers chloroform and then at once gives veratrum in large doses, maintaining the pulse at the normal rate. The lessening of the blood-pressure quiets the excitement of the cortex, perspiration follows, and elimination of the toxic substances by the kidneys is increased. He also prefers veratrum to the coal-tar products in the onset of infectious diseases, as scarlet fever, pneumonia, influenza, meningitis, etc. He spoke of its use in the treatment of pneumonia at length, and believes that the objection which has been raised against its use, i. e., that it depresses and weakens the heart, has little weight when compared with its favorable effects.

Dr. W. G. Moore said that when he entered the profession, twenty-five years ago, veratrum was a settled remedy, and he intends to go back to veratrum because of old associations, and because of the failure of other remedies in pneumonia.

Dr. Robert Barclay has recommended veratrum in middle ear disease. In "Hare's System of Therapeutics" he contributed an essay on its use in the early congestive stage of middle ear disease. He considers it is fever of the sthenic type and a bounding pulse.

Dr. W. Hutson Ford wondered that any one dared mention veratrum viride, for it has been systematically decried by all the dullards of the profession. He has been a ceaseless student of the drug, beginning its use in 1857, four years after Norwood first brought it prominently into notice. He used Norwood's tincture only, as none other approached it in uniformity or certainty. While a young practitioner, in 1857, he had twenty-four cases of typhoid in one epidemic. The first two were treated in consultation with an older physician in the old way, and both died. Being at that time especially engaged with a study of the production of animal heat in the economy, and its effects in disease, in wasting the muscular and nervous tissue, and predisposing to all forms of local congestion and parenchymatous inflammation, he determined to use veratrum and so limit the intensity of all the features of the disease. His success was complete, and the severity of the cases was at once abated. Upon this basis he used it in conjunction with mercurial evacuants, in the rest of the 24 cases of typhoid fever, and all got well, as everybody else's cases do, however, for that matter. In 1849 he gave veratrum in the treatment of 183 cases of yellow fever, with a death-rate of 8 per cent.

Dr. R. M. Funkhouser was surprised that Dr. Saunders had not mentioned Fordyce Barker, who did much to popularize this drug. If we could educate our nurses to watch its effects we would better know how to give it. Veratrum is a drug to be studied, and is more difficult to understand than digitalis. Another difficulty is the absence of a standard in drugs—a uniformity of strength—so that doses can not be relied on.

Dr. A. R. Kieffer said that he had had no personal experience with veratrum, but had come to rely more on his vis medicatrix *naturæ*. Purgation, if too active, he believes, would defer solidification and prolong the attack in pneumonia.

Dr. T. M. Hopkins recalled a late case in which the patient, after going skating, developed the classic symptoms: pulse 134, respiration 40, temperature 104.6 F. He recovered speedily under veratrum. He pushes the drug until the patient vomits, then reduces the dose to one-fourth, until the patient perspires freely, perhaps twelve to fourteen hours. At the same time he uses calomel, ipecac, etc., or an injection. Veratrum also does well in appendicitis, together with early and frequent injections.

Dr. H. Jacobson said that he was called in consultation to a case of puerperal eclampsia, the second attack in two years. The urine was loaded with albumin casts and blood-corpuscles. Veratrum, saline injections, hot packs and chloroform inhalations were given for five hours and the patient recovered from the convulsions, although the nephritis was still present, and had been for several years before confinement.

Dr. John Zahorsky said that veratrum viride seemed to work favorably in influenzal pneumonia and in the pneumococcic infections also. Its use, however, must be studied well and long, and the point of change from veratrum to stimulants carefully watched for. For the first three years of his practice he was utterly discouraged in pneumonia, but he now uses veratrum and feels that he can accomplish a little.

Dr. A. Ravold said that he tried veratrum in pneumonia at the City Hospital, and came near having disastrous results in the first case. There were pallor, exhaustion and sweating. High fever indicates the use of remedies that diminish heat production or cause heat dissipation or combinations of the two effects, and he asked the essayist to elucidate this point.

Dr. J. H. Tanquary felt that the toxic effects of veratrum viride had been magnified. It does produce nausea, vomiting, etc., but there are few deaths on record from its use. From experience he felt that veratrum was the best remedy in the acute stage of pneumonia. Purgation and blood-letting were also useful.

***Dr. Saunders**, in closing*, said Norwood's tincture is most reliable. We can speculate on the manner in which it reduces temperature, but with little use. It is not a powerful antipyretic, but acts slowly and never excessively if used carefully. Some years ago an Italian exploited digitalis as a germicide in pneumonia. Another said he could make a diagnosis by its effect on the temperature. He tried it faithfully and found the claim to be a humbug. Digitalis is not an antipyretic. In anginæ of "grip" origin, highly painful, with symmetrical, deep redness of the fauces and edema, he obtains quick relief from veratrum, giving a drop on the tongue every fifteen minutes. In five cases thus treated, deglutition was almost impossible in two. In articular rheumatism he uses it in combination with salicylates, also with excellent effect in beginning appendicitis and pelvic peritonitis.

CHICAGO MEDICAL SOCIETY.

Meeting held March 6.

The president, Dr. J. H. Stowell, in the chair.

The evening was devoted to a "Symposium on Sanitation."

Demands of Sanitary Science.

Dr. H. M. Bracken, St. Paul, Minn., secretary of the Minnesota State Board of Health, read a paper on this subject. He said that one of the first things that comes under the control of the sanitarian is the suppression of a nuisance, which may be defined as some feature objectionable to the sense of sight, smell or hearing, or a menace to health. It does not require very close observation to note a nuisance, be it in the form of filth in streets or alleys, or about private residences or public buildings, or in public conveyances. The ease with which a nuisance is suppressed depends decidedly upon the conditions which surround it. A nuisance of marked quality or quantity in the better districts of a city would not be tolerated for a single day, while a similar condition might be continued indefinitely in the slums, either because of the indifference of the people to its existence, or the negligence of sanitary officials or landlords. The bearing of sanitation upon a nuisance is so generally recognized that in dealing with one the almost universal question is: What effect has it upon the health of those annoyed? If it can be proven to have a deleterious effect, half the battle for its suppression is won. Many of the apparently pronounced nuisances are decidedly injurious to health. Here it is that the demands upon sanitary science begin. The bacteriologist and the chemist determine the degree of danger; while the sanitarian determines the means of its abatement or removal.

The disposal of refuse taxes the ability of the sanitarian according to the varying conditions present in large and small cities. Refuse includes street sweepings, various cast-off articles of clothing, or factory, kitchen garbage, manure, dead animals, ashes, etc. Kitchen garbage has a food value in the feeding of hogs, and any city with a population not exceeding

300,000, and surrounded by an open country, should find but little if any trouble in disposing of such material at comparatively little expense. It may be necessary to dispose of it by cremation, but this, as a rule, is a wasteful method and expensive, and is to be avoided when possible. The proper disposal of garbage without cremation calls into play the proper construction and use of collecting vans; the proper construction and care of feeding pens; the proper organization and control of a sanitary system of inspection, and the proper care of the animals to be utilized as scavengers.

Closely related to garbage and waste disposal is the disposal of sewage. The problem is largely one of engineering. It is quite generally the custom to conduct sewage to the nearest stream into which it can be discharged, thus converting a natural water-course into an open sewer. By this method the safe supplies of drinking water are cut off. It therefore becomes a commercial as well as a sanitary proposition to determine which is the wiser course: to turn sewage directly into streams, thus destroying natural water-supplies, or to filter the sewage before it enters the streams, thus leaving the natural water-courses unpolluted. The essayist believes that the latter is the correct course.

As to the control of the spread of infectious diseases, probably there is nothing that will accomplish more than a thorough system of school inspection. School inspection does not cover the entire problem of proper sanitation for schools, for the proper ventilation, heating and lighting of school buildings, together with an insistence upon the individual cleanliness of pupils, places a great responsibility upon architects, which too often is not recognized.

In dealing with diseases that are highly infectious the proper isolation of patients is important. The ordinary methods of quarantine now practiced are barbarous, for with the appearance of certain infectious diseases in a family the entire household is tied up; the well with the sick. This may be quite satisfactory for the community at large, but he believes it is unfair to those not ill to be put in quarantine, for it subjects them to the maximum danger of infection. Patients ill with an infectious disease that is readily communicated to others should be promptly removed to an isolation hospital, unless there is ample opportunity for isolation in the residence.

Of all infectious diseases demanding attention pulmonary tuberculosis probably holds first place. He thinks it is criminal negligence not to provide special hospitals or homes for the tuberculous. The state can well afford to spend many thousands of dollars for the construction and care of sanatoria for these unfortunates, even should such action be looked upon as a protection for the well rather than as a means for caring for the sick.

It rests upon physicians in this country, through their various medical organizations, to transform the great body of medical sanitarians into medical specialists beyond and above the influence or control of politics.

State Aid in Prevention of Tuberculosis.

Dr. Charles O. Probst, Columbus, Ohio, secretary of the Ohio State Board of Health, followed with a paper on this subject. He presented a brief argument in favor of the following propositions: 1. The state should provide hospitals for the reception of persons suffering from tuberculosis, and should assist municipalities or counties to construct similar institutions. 2. Physical education, conducted by trained medical men, should be made a part of the common school course; and students in normal schools, colleges and universities should be instructed in hygiene, including a proper knowledge of the causes and prevention of tuberculosis. 3. The state should exercise a much closer supervision over the construction, ventilation and care of workshops and factories, especially where the occupation is conducive to tuberculosis. 4. The state should prohibit the sale of milk from tuberculous animals, and should provide for the inspection of dairy cattle. It should enforce the proper stabling and care of such animals.

In 1890 the census returns gave a mortality from consumption alone, in Illinois, of 5698, or 149 deaths per 100,000. The victims are mostly young adults—the bread-winning men and child-bearing women; hence the loss to the state is much greater than the mere number of deaths would indicate.

The individual, even if properly instructed, is, in a large measure, unable to protect himself against this widely prevalent disease. The state should therefore assist him, not only because it is its duty to protect its citizens against dangers of a general character, but also to protect itself against the unnecessary loss of its working capital—healthy men and women. Admitting these premises, the essayist then proceeded to discuss the ways and means.

The first thing proposed is state hospitals, and municipal and county hospitals, erected with the assistance of the state for the reception of consumptives. The state hospital may be for the reception of selected, recent cases, with the expectation of curing and returning to society many of its useful members who must otherwise perish, or it may receive patients who, on account of surroundings, are especially liable to give rise to other cases of the disease. The latter plan is more directly in line with preventive measures. The former is the one usually adopted by the state, as giving, under present conditions at least, greater returns. State hospitals for the cure of consumption favor its prevention. Not only are patients isolated who may spread the disease, but they receive there a training which, on being returned to their homes, makes them an important aid in disseminating among the people correct ideas of measures for the prevention of consumption—measures which should be practiced in the homes of all consumptives.

The essayist urged the erection of a hospital for consumptives, by the state, for the treatment of carefully selected cases. It would seem to be wise, at least in the beginning, that patients should pay the greater part of the operating expenses. The charge of $5 a week, established for the new Massachusetts Hospital, appears to be a reasonable one. Hospitals more strictly for the prevention of tuberculosis should be established by municipalities, or possibly by counties. The aim here should be to select and isolate those cases which are the greatest danger to the public. Such cases are usually found among the unfortunate, poorest classes. Many of these find their way into general hospitals or have to be treated in their homes at public expense.

He urged the physical education of school children, with the teaching of hygiene and the cause and prevention of consumption to students in advanced institutions of learning. Practically no attention is given to the physical education of school children. Where school gymnastics are practiced, they are not conducted or supervised by persons having the necessary knowledge of the subject. There is no individualism in such work. All are treated alike. School children, in his opinion, should be under the constant supervision of a specially trained medical inspector. They should be measured and weighed periodically. Special exercises, as, for example, singing or other lung exercises, should be prescribed and enforced when needed. Parents should be notified of marked physical defect, and urged, in proper cases, to consult the family physician where medication or special diet seemed to be indicated. He would urge that hygiene be taught in high schools, normal schools and universities. A proper understanding of the causes and means of prevention of tuberculosis would form but a part of the great benefits to be derived from such teaching.

The essayist then discussed at length the direct and indirect causes of consumption, and stated that it is uncertain to what extent tuberculosis is due to the ingestion of milk, butter and meat from tuberculous animals.

Miscarriage of Municipal Sanitation.

Dr. Ernest Wende, health commissioner of Buffalo, N. Y., read a paper of which the following is a summary. There should be: 1. Unity of law, procedure and action throughout the state in regard to contagious diseases; even further in this relation, throughout the states, interstate contagious disease laws. 2. Interstate law covering contagious diseases in animals, particularly tuberculosis. There seems every reason for believing that the pathology of the superior animal—man—would be benefited by such legislation. 3. The vesting of city health officials with certain state board of health inspection powers to permit them, under certain circumstances, to extend their action beyond the municipal confines. 4. Municipal sanitation and state medicine to be made a more important feature in education, particularly in universities. It should be made contingent that health officers qualify by such a course of study before being eligible. 5. Requirements of sanitary education everywhere; in the public schools, in the high schools, colleges and universities, so that by the time the younger generations mature enlightenment will have reached our various legislative bodies. 6. Selection of municipal health officers for their fitness, with secure tenure of office and proper compensation. The municipality should not be exposed to an unnecessary risk by politics.

Dr. Arthur R. Reynolds, health commissioner of Chicago, reviewed, by the aid of lantern slides, the work of the Department of Health of Chicago from 1851 to the present time.

Dr. John A. Robison, in the discussion, emphasized the fact that the state is in duty bound to enact such laws as will prevent the spread of tuberculosis. If there were 800,000 cases of smallpox in Illinois, the inhabitants would be panic-stricken and legislators would not hesitate to appropriate any amount of money to stamp out the epidemic; and yet tuberculosis is present with us all the time. It is not so virulent as smallpox, but it is ever-present and more insidious in its contagiosity and infectiousness. He mentioned two methods for stamping out this disease: 1, by educating the inhabitants, by teaching hygiene and the causes and nature of the spread of the disease in high schools, colleges and universities; 2, by the state educating the people that the disease is preventable and curable.

Dr. William A. Evans stated that the United States government at the present time is inspecting meat very thoroughly, for the protection of its foreign trade. The governments of foreign countries demand the inspection of meat, and commercial considerations require that the demands be complied with. The city has a legal right to control all of the cows that are to supply it with milk, and while the people who supply this milk are not inhabitants of the city, are not directly amenable to the city laws, their products are amenable to the laws of the city, and therefore the suppliers of milk are indirectly amenable to the laws themselves.

One of the most urgent necessities confronting the people of Illinois is a law requiring a certificate of death before a burial can be made. He has talked this matter over with some of the police and cemetery authorities and has been assured that they would give such a law their hearty endorsement.

Dr. George W. Webster stated that such a burial law has been framed by the State Board of Health, and will be introduced at the present session of the legislature.

Dr. Denslow Lewis stated that when he acted as a health officer in Hyde Park, Chicago, he met with violent opposition, not only from the public, but the medical profession, in his endeavor to enforce the requirements of the State Board of Health, which had just then enacted certain regulations, as well as in endeavoring to enforce municipal ordinances. He spoke of the British laws and the manner in which they are enforced, and of a plan adopted by the Indiana State Board of Health by which orders can be properly executed.

PHILADELPHIA PATHOLOGICAL SOCIETY.

Meeting held February 28.

President Dr. Frederick A. Packard in the chair.

Carcinoma of Appendix.

Drs. Richard H. Harte and Robert N. Wilson, Jr., exhibited speciments of a primary carcinoma limited to the vermiform appendix, from a woman 24 years of age, whose family history was negative. She had been well until 16 years of age, when she may have had chlorosis. When 19 she suffered from a severe pain in the right iliac region, and it was supposed she had an attack of appendicitis. Several months later she passed blood in the feces. When seen she had a persistent sharp pain over the region of the vermiform appendix, and also complained of a dull pain in the lumbar region. The blood-count was practically normal. The spleen was tender, but not enlarged. On December 2 a mass was found in the region of the appendix, which could be rolled around under the fingers. At this time the leucocytes were increased.

An operation was done at the Pennsylvania Hospital. In the appendix some fecal concretions were found, but for the most part the lumen was closed. The appendix was ligated and removed, and sections showed undoubted carcinomatous growth which had not begun to involve the neighboring strucstructures.

Dr. A. O. J. Kelly said he had seen several cases of carcinoma of the appendix. In these cases the lumen had mostly been patulous. In his opinion carcinomas of this organ may be more common than supposed.

Melanosis of Cerebrospinal Membranes in Rabies.

Drs. D. J. McCarthy and M. P. Ravenel exhibited specimens of melanosis of the cerebrospinal membranes in a case of rabies. The specimens were obtained from a cow dead of rabies. The cerebrospinal membranes were deeply pigmented, but he did not know how far down the cord the area extended. The pigmentation affected the pia, arachnoid and dura. Tests for iron gave negative results. Distinct endarteritis was also present.

Dr. David Riesman had seen similar black pigment in cerebrospinal membranes in the human subject, for the most part limited to the region of the medulla.

Injuries to the Brain.

Dr. Wm. S. Wadsworth read a paper on this subject, based on about sixty observations during the past two years. He pointed out the nature of the injuries resulting from direct and indirect violence, and said that in studying these cases one must consider the vital condition of the parts, e. g., of the nerve tissue, the membranes and the bones. The condition of the blood before and after the injury is also important. The character of the wound in some respects depends on the nature of the weapon, as for instance the wound resulting from an iron rod would be different from that of wood of the same weight and form. One must also study the condition of the blood-vessels, since in alcoholism there is less resistance of the blood-vessels and nerve tissue. This should be remembered, since, during the normal condition, there is a sort of physiologic massage kept up by the circulating blood. If the carotids are atheromatous a compensatory condition of the coronaries will also occur. In some cases the skull may be abnormally brittle, or abnormally thin, and hence injuries may more easily occur. He has found that by compressing the skull with the hands, from before backward, the foramen ovale can be made to change its shape quite readily in some cases. Should this occur suddenly during life the vital structures in the region will be compressed. In some instances hemorrhages may result from the blood-vessels somewhat removed from the seat of compression. Compression of this kind may follow blows on the chin. In the chronic insane, the bones of the skull are at times abnormally brittle, and in the intellectual the bones of the skull are frequently abnormally thin.

Dr. Wm. G. Spiller referred to a case of brain tumor in which the bone over the seat of the growth was considerably thickened.

Lenticular Carcinoma of the Skin.

Dr. M. B. Hartzell exhibited specimens of this affection on the right lower extremity. Its occurrence had been in the form of discrete nodules, for the most part distributed to the upper and inner surfaces of the thigh. They were usually about the size of a pea and slightly pinkish in color. Most of the growths were covered with a crust which, on being removed, left a small ulcer. One of the nodules appeared on the foot and sections seemed to prove that it was of a malignant character. The cells were for the most part large and oval, with large, deeply-staining nuclei. The protoplasm was poorly stained.

Dr. David Riesman thought the tumor rather peculiar, and in some respects resembling a sarcomatous structure. It did not appear to be made up of squamous epithelium, and may have originated in the hair follicles.

Dr. Jay F. Schamberg stated that usually lenticular carcinomas are secondary to carcinomas of the breast.

Tumors of Sciatic Nerve.

Dr. John B. Roberts presented specimens of multiple tumors of the sciatic nerve. The man from whom the growths were removed had for many years noticed them, some located in the popliteal space. He complained of excessive heat, and some sweating on the affected side. An operation was performed and some of the growths removed showed that they were of a myxomatous character.

CINCINNATI ACADEMY OF MEDICINE.

Meeting held February 25.

The president, Dr. Charles L. Bonnifield, in the chair.

Multiple Symmetrical Lipomata.

Dr. Horace J. Whitacre presented a male patient, aged 37, whose present trouble was first noticed about six years ago as swellings in the parotid region, appearing simultaneously; both sides of the neck and the groins were affected similarly, and at approximately the same time. Since this time these enlargements have appeared and disappeared about twice a year, and the patient himself ascribes the cure to large doses of whisky. The present tumors appeared a few months ago, and did not respond to the usual treatment. These swellings have never become inflamed and have never been painful. *Location:* parotid regions, over the mastoids, doubling the chin, in the mammary glands, on each side of the median line of the abdomen, in the inguinal regions, and in each popliteal space. Some of them are as large as a man's fist. The skin over the tumors below the neck is imperfectly movable and suggests the pig-skin dimpling of a lipoma. The nutrition of the man is excellent. *Blood examination:* reds and hemoglobin, normal; whites show a slight leucocytosis. On removing a piece of the tumor from one of the enlargements of the neck, and also from the groin, they were found to be composed of fatty tissue. The reporter seemed to think that the occurrence of these tumors symmetrically gave weight to the theory that they depend on some derangement of the trophic nervous system. As regards their appearance and disappearance, he stated that possibly, under the influence of the enormous doses of alcohol the patient ingested the trophic centers might have been stimulated to normal activity.

Glycosuria Due to Congenital Phimosis.

Dr. R. C. Jones considered this subject in a clerk aged 21. In the fall of 1899 he had a severe attack of scarlet fever, from which he did not convalesce very readily. He steadily lost flesh and strength, and on consulting a physician a few months later was informed that he had diabetes. Becoming no better at the end of three months, he consulted another, who confirmed the diagnosis, but was unable to help him in four months' treatment. During this period his weight fell from 143 to 124 pounds, his appetite became poor, he drank large quantities of water, and passed from five to seven pints of urine a day. Insomnia and despondency became marked. Urinalysis, as made by Dr. Jones, showed sugar, the passage of an average of six pints of urine a day, and a specific gravity of 1030. At the end of two weeks' treatment he was no better. At about that time the patient called his attention to a feeling of irritation and discomfort at the end of the penis, and on examination there was found a congenital phimosis, a soft tight prepuce, and a slight balanoposthitis. Circumcision was advised and performed, and within two weeks a marked improvement was noticed. All medication and dieting were stopped, and within four weeks the sugar had disappeared, specific gravity was 1017, the amount lowered to three pints a day, appetite improved, and his nervous symptoms had completely disappeared. Repeated examinations have failed to reveal the presence of sugar at any time, and in the interim he has gained eighteen pounds in weight.

Case of Appendicitis.

Dr. George B. Orr reported cases, one of which presented features of unusual interest, as follows: For three months before first seen the patient had complained of frequent attacks of nausea, irregular chills, followed by fever and sweats, loss of appetite and constipation, and constant severe pain internal to the iliac crest, which pain often extended to the knee. On physical examination he found marked tenderness over the entire right side of the abdomen, with swelling and fluctuation extending from Poupart's ligament upward and backward over the crest of the ilium to within three inches of the spinal column. He advised immediate operation, which was accepted. A posterior opening was first made and then an anterior one; through the latter was found an abscess cavity that reached from Poupart's ligament backward to very near the spinal column. The appendix could not be found, and no very lengthy search was made for it. About twenty ounces of pus were removed, and through-and-through drainage made. Healing occurred rapidly, with the exception of a small fecal fistula, which was lightly curetted on several occasions without success. He then had the patient put to bed, at complete rest, and had the bowels thoroughly moved. He was given nothing to eat but a teaspoonful of Wyeth's beef juice every two hours, and water in abundance. At the end of ten days the fistula healed entirely and has remained closed ever since.

Membranous Enteritis.

Dr. Mark A. Brown reported the case of Mrs. W., aged 28, married, well-developed and apparently well nourished. The duration of her present trouble is about nine months, her chief complaint: attacks of severe abdominal pain, colicky in character, followed by the appearance of mucus in the stools. Previous to an attack, usually the bowels were constipated, while immediately following, diarrhea supervened for several days, often followed by tenesmus. Gastric symptoms, such as nausea, anorexia, eructations and a sense of burning pain in the stomach always accompanied these attacks. Vomiting, too, was almost always present, and often fever of a mild grade. The duration of each attack was from four to five days, followed by a period of two weeks, during which she felt quite comfortable. In all she had lost between forty and fifty pounds in weight. Physical examination of the heart, lungs and abdomen was entirely negative, aside from slight tenderness in the epigastric region; there was no abdominal distension. Digital examination of the rectum was negative. The uterus was slightly prolapsed. The stools, during the time that she was at the hospital, were not more than one or two a day, usually coming with enemata, and consisting of fecal matter and mucus, the latter appearing in the form of strings (casts) a foot or more in length, or in smaller masses or clumps—the latter condition particularly after the use of nitrate of silver injections. These masses were shown to be of mucus, by means of the Ehrlich triacid stain. Under the microscope, the fibrillary nature of the deposits, together with the nucleated cells with tail-like extremity, resembling spermatoza, could be readily distinguished. She was sent to the Presbyterian Hospital, put at complete rest in bed, and upon a light (almost a milk) diet. Nitrate of silver injections, then boric acid injections were used without the slightest avail; the two were used alternately, but the patient was, if anything, worse. These medications were always used in the form of high enemata, the lower bowel having been previously evacuated by means of a simple enema. This plan of astringent injections was finally abandoned and daily high injections of olive-oil substituted. She was given these late in the morning or early in the afternoon and was able to retain them without discomfort for from twelve to twenty-four hours. Improvement was immediate under this plan; in three days no mucus could be detected in the stools, and in a week she was discharged from the hospital practically well. The olive-oil enemata were discontinued gradually. When next seen by the essayist, about three months later, she was entirely well, and had had not the slightest sign of recurrence. She had steadily increased in weight.

Leucoplakia Linguae.

Dr. M. L. Heidingsfeld demonstrated, from lantern slides, a case of leucoplakia linguæ of ten years duration, in an individual infected with syphilis, the latter of twenty years' duration. Some of the leucoplakia areas were the size and thickness of a split butter-bean, and a radical surgical extirpation was made of these in November, 1900. Pathologic examination revealed the condition to be distinctly pre-epitheliomatous in character—marked proliferation and down-growth of the epidermis and areas of degeneration with a nest-like arrangement of the epithelium. A good wall of connective tissue separated it from underlying structures. A cellular infiltration was nowhere evident, and the only pathologic evidence of syphilis was an endarteritis obliterans.

Venereal Warts of Tongue.

DR. **HEIDINGSFELD** also showed, by means of lantern slides, specimens of extragenital venereal warts of the tongue, taken from a case shown at the Academy Nov. 28, 1900. Some exception was taken to the diagnosis at that time, but the pathologic examination has revealed the lesions to be typical venereal warts corresponding in appearance and structure to the same lesions on the genitals of the case in question. He also reported another case with the same distribution, showing the same pathologic structure, which case had recently come under his notice.

Accident Attending the Adenoid Operation.

DR. C. R. **HOLMES** reported a case in which the sharp blade of the Gottstein curette became broken off at the beginning of an operation for adenoids. The blade was abstracted from the pharynx with the greatest difficulty. Since that time he has had an instrument made, after a design of his own, by which the cutting blade is greatly reinforced, and can consequently bear a greatly increased pressure.

DR. **STOWE GARLICH** reported a similar accident, but the broken piece was swallowed. Fortunately it was passed in the stools a few days later, without apparently causing any damage.

Adenomatous Hyperplasia of the Rectal Mucosa.

DR. A. J. **WHITACRE** presented a case of adenomatous hyperplasia of the rectum in a woman aged 63, which tumor had existed for about four years. He also described a new operation for removal of growths in this region with but a minimum blood loss.

Multiple Abscesses of the Liver Following Latent Appendicitis.

DR. **GEORGE P. DALE** gave the history of this case. Throughout the patient's two months in the hospital it was one of sepsis with no localizing symptoms, so that he came to the post-mortem without a positive diagnosis having been made. At autopsy the chest showed nothing abnormal. The cecum was bound down by adhesions and imbedded in a mass of greenish, foul-smelling pus. The abscess was well walled off from the general peritoneal cavity. The stump of the appendix was all remaining of that organ. The liver was about 2½ times as large as normal, and the seat of multiple abscesses of various sizes, the largest being about 1½ inches in diameter. The kidneys were much reduced in size, with granular surfaces and adherent capsules. Scattered throughout the cortices were numerous small embolic abscesses, not yet broken down. The cortex was about one-third its normal width.

Aneurysm of the Abdominal Aorta.

DR. **GEORGE P. DALE** said that a diagnosis was not made in this case as there were no localizing symptoms. Indeed, the man was thought to be suffering from phthisis, and numerous examinations of his sputum were made with negative results as far as the finding of tubercle bacilli were concerned. Death was sudden. Autopsy showed the right ventricle dilated and empty, the left much contracted. In the diaphragm, two inches from the median line to the left, was a perforation easily admitting a finger, the edges ragged. The left pleura contained a large amount of clotted blood and about a pint of semifluid blood. The abdominal aorta, beginning just below the diaphragm, was transformed into a sac, adherent to the vertebræ, diaphragm, liver and stomach: the tenth, eleventh and twelfth dorsal and first and second lumbar vertebræ were eroded, both the bone and cartilage. The aneurysmal sac was covered anteriorly by the liver. The latter was much deformed and covered with puckered scars, in all probability due to syphilis. Rupture had occurred into the left pleura through the opening mentioned.

Aneurysm of the Innominate; Ligation of Common Carotid and Subclavian; Disappearance of Tumor for Sixteen Months; Return.

DR. **JOSEPH RANSOHOFF** presented a patient on whom he had operated about sixteen months previously, for the relief of this condition. The returning tumor has not yet grown to any great size.

PHILADELPHIA ACADEMY OF SURGERY.

Meeting held March 4.

President Dr. DeForest Willard in the chair.

Compound Fractures of the Skull.

DR. **RICHARD H. HARTE** read a paper entitled "Some Observations on Compound Fractures of the Skull." He considers the diagnosis of fracture of the vault as sometimes easy if the wound extends down to the bone, though in some cases a roughness of the bone simulates a fracture, after an incision becomes necessary to clear up the diagnosis, and in such cases he believes it always justifiable. Children frequently suffer from fracture of the bones of the skull, which are never recognized. Simple incised wounds are sometimes mistaken for fractures. As to fractures of the base, an accident of this kind may be caused by a fall on the back of the head, in such cases involving the posterior fossa. Fractures of the anterior fossa may involve the cribriform plate, or petrous portion of the temporal bone. The prognosis of fractures at the base of the skull depends on the nature of the injury. If the brain substance has been injured the prognosis is more unfavorable. The diagnosis of fracture of the base of the skull may be made by the escape of blood from the eyes, or ears, and by the impairment of nerves of special sense. The speaker recalled an instance in which a small amount of brain tissue had been lost in such an injury. When a mixture of blood and cerebrospinal fluid occurs, it may be ascertained by rubbing a small amount of the fluid between the fingers. If any cerebrospinal fluid is present its character will be noticed, while if it is only blood, it will become sticky. The nerves of special sense may be injured at their origin, or along their course and may be from compression. The presence of coma is not always diagnostic of fracture of the base of the skull. Coma should not be ascribed to alcoholism. In alcoholism the temperature is normal. Of the speaker's series of fractures of the base of the skull, about 30 per cent. had recovered.

As to the treatment, rest in bed, with ice to the head and an antiseptic dressing, together with the internal administration of calomel and Dover's powders, seemed to give the best results. When depression is present the case becomes at once an operable one. Even in doubtful cases an exploratory incision should be done. If the wound becomes infected a drainage-tube should be inserted to a point just below the depth of the bone. Of the twenty-three operable cases of fracture of the skull seen by the speaker, 11.5 per cent. died.

DR. **JOHN B. DEAVER** expressed belief that the results obtained by Dr. Harte in the treatment of this series of cases had been good.

Neuropathic Affections of Bones.

DR. C. H. **FRAZIER** presented a patient showing a peculiar neuropathic affection of the bones, with skiagraphs. The patient was a man 60 years of age. Three years ago he had complained of pain in the right knee, accompanied by swelling. Skiagraphs show osteophytes growing from the articular cartilages. The process has also involved the left knee. The special features of the case are that it is a bilateral affection having lasted for years, and with no tendency to involve other bones. The case resembles osteosclerosis, rather than osteoporosis, or it might properly be classified as one of osteitis deformans.

Left Cecal Hernia.

Dr. John H. Gibbon read a paper entitled "Left Cecal Hernia, with Report of Two Cases." He believes that this condition occurs more frequently than has been supposed, since it has not been the practice to open the sac. More recently certain operators have met with the condition repeatedly. In the first case, the man suffered with hernia for years, and later strangulation occurred. On opening the sac both the cecum and ilium could be easily seen. The patient recovered from the operation, but later died, probably of heart disease.

The second patient was a laborer, 55 years of age, who had suffered from a hernia extending almost to the knee. Dr. W. W. Keen operated, by aid of spinal anesthesia. Two days afterward the man developed stricture of the urethra, and later died of symptoms of sepsis, probably of kidney origin. The speaker considers cecal hernia very rare in women, and the most frequent cause of the condition an abnormally long mesocolon.

Obstructive Jaundice.

Dr. John B. Deaver read a paper on "Mortality in Operations for Obstructive Jaundice." He enumerated the causes of the condition as outlined by Murchison and Osler. Peritonitis is not a common cause of death in obstructive jaundice. The effects of the bile salts on the blood seem to increase the tendency to excessive bleeding, and to secondary hemorrhage. He lost a case from secondary hemorrhage following an operation for this condition. To lessen the tendency toward this condition he gave calcium chlorid, but could not speak definitely as to its effects. Suprarenal extract in one case did good. Hemorrhage and shock are common causes of death. These facts seem to indicate that the sooner an operation is done the better will be the prognosis. It is better to open the abdomen and find nothing wrong than to wait until later and then find an irremediable condition.

Dr. J. H. Gibbon asked the speaker whether he had ever met with a case of acute dilatation of the stomach in these operations.

Dr. R. G. Le Conte asked whether he had ever tried gelatin to lessen the tendency to hemorrhage.

Dr. Deaver stated that when there is dilatation of the stomach it is the result of the general septic condition. He has not tried gelatin.

Enterectomy in Strangulated Hernia.

Dr. T. S. K. Morton reported "A Case of Strangulated Femoral Hernia; Herniotomy; Acute Obstruction Three Weeks Later; Enterectomy: Recovery." In this case taxis had been tried before the patient was seen by the speaker, but without result. He did herniotomy, and replaced the bowel. A few days later abdominal colic occurred, and three weeks later there were symptoms of obstruction. He opened the abdomen and found an obstruction. Enterectomy was done by means of the Downes forceps. About eight inches of the bowel was removed and the patient made a good recovery.

Dr. John B. Deaver stated that he had often thought that the white line, as found at the time of herniotomy, might be the subsequent seat of obstruction of the bowel, owing probably to cicatricial tissue formation at that spot.

Suppurating Hematocele.

Dr. George Erety Shoemaker read a paper entitled "Treatment of Suppurating Hematocele Following Extra-uterine Pregnancy." In doing this operation he prefers the abdominal route. Pelvic hematocele can, however, be best drained through the vagina.

CALIFORNIA ACADEMY OF MEDICINE.

Meeting held February 26.

Appendicitis During Typhoid.

Dr. Beverly MacMonagle reported two cases of appendicitis operated on during the course of typhoid fever. The first was in a young man of 18, who, at the end of the second week of a typical attack of typhoid, suddenly complained of a severe pain in the right iliac region, and the temperature rose to 105. The Doctor was called in consultation the same day, and found considerable general tenderness, decidedly increased in the right iliac region, with muscles tense to the point of spasm on slight pressure, and apparent increased dulness in the groin. Rectal examination showed decided tenderness in the rectovesical cul-de-sac, particularly on the right side. The spleen was enlarged, the liver dulness normal. A blood count showed a leucocytosis of 17,000. Abdominal section was determined on; the only question being between perforation and appendicitis. The appendix was removed. The temperature came down to 103 and the pulse to 110 the following day. The patient went through the usual course of typhoid to recovery. The anesthetic and operation did not seem to add any additional trials to his case.

The second case occurred in a man 27 years of age. Nineteen days from the commencement of his typhoid he had a chill, and began to vomit and suffer severe pain in the abdomen. Temperature went up to 105, pulse 156, respiration 38. The abdomen was tense and tender, with rigid muscles over the right iliac region. While he could not detect dulness, he thought he could feel some thickening over the appendix. Incision was made and the appendix removed. Temperature in twelve hours was 102, the bowels moved and the stools had the appearance of containing blood. The patient vomited a good deal and the pulse was not satisfactory. On the second day after operation vomiting ceased and the patient was more comfortable, the pulse and temperature much the same. The third day a blood count showed leucocytosis of 19,000, pulse and temperature were the same, and the bowels moved freely. On the fourth day the temperature was 104, pulse 142, respiration 34, with a slight chilly feeling, and some pain in the seat of operation. Examination showed pus in the abdominal wound, which was evacuated, when the temperature and pulse fell. After this the patient progressed very well, the abdominal incision discharging pus for twenty-two days, when it closed and convalescence was established.

Dr. W. W. Kerr said that the combination of the two diseases was by no means uncommon. He had had two such cases, one a perforation close to the end of the appendix, with ulceration extending down into the appendix itself. He thought it a question whether we should recommend operation as promptly as in cases where typhoid did not exist. The presence of typhoid should make us more cautious.

Dr. J. Henry Barbat said he was particularly interested in these reports because a man on whom he recently operated had typhoid fever nine months before. His attack then looked like appendicitis, but a diagnosis of typhoid was made. He never got entirely well, but had pain in the right side at times. Recently he had an attack of gall-stone colic, for which he operated, removing a small stone, and found the appendix very firmly bound down by adhesions, which made it very difficult of removal. It is reasonable to suppose that he had an appendicitis along with his typhoid.

Dr. T. W. Huntington said that the coexistence of the two diseases has long been recognized. There can be no question regarding the propriety of operating in these, for the patients stand operation very well. He considers the blood count of special value in determining the existence of appendicitis.

Dr. George M. Hughes said that patients having typhoid react well from operation. He has seen several operated on for perforation, and, where ether was used, the patients came off the table with better pulses than before. He thinks we should operate in all cases of appendicitis complicating typhoid. We may be in doubt as to whether pain is due to appendicitis or typhoid ulcer, but operation will add no danger for the patient, and it would be better to err on the safe side and operate.

Dr. MacMonagle said that this was the extent of his experience in such cases. The question was whether one should operate in cases in which the pain became very severe, with poor pulse, shallow respiration and vomiting. The question of perforation was left out, because the temperature went so high.

Carcinoma of the Pylorus and Stomach.

Dr. T. W. Huntington exhibited a specimen showing the result of an operation for carcinoma of the pylorus and of the stomach. On Aug. 5, 1900, pylorectomy and partial gastrectomy was performed upon a man 67 years old. At the time of operation the pylorus was almost entirely obstructed by the growth. After removal of the pylorus and a considerable portion of the stomach, the divided end of the duodenum was attached to the posterior wall of the stomach by a Murphy button. There was rapid recovery from the operation. For three months the patient gained perceptibly; his weight increased 35 pounds; he ate a promiscuous diet with relish. He then began to fail, with a recurrence of former symptoms, and died Dec. 24, 1900, nearly five months after the operation. At autopsy, there was extensive carcinomatous involvement of the stomach along the lesser curvature, and at the point of anastomosis, also of the liver and pancreas.

Dr. MacMonagle said that it was a question whether or not the doctor should have taken out more of the stomach. He has had one successful and one unsuccessful case. In his fatal one he had not taken out a sufficient number of glands. He thinks statistics show that the result is as good in gastroenterostomy as in total removal of the stomach. In this specimen of Dr. Huntington's the union showed that the stomach had attained its original condition of strength. Recurrence was beyond prevention.

Dr. Barbat said that in the majority of successful cases the anastomosis is made with the Murphy button; it saves time if properly applied, prevents leakage, and in general gives a better and safer result, and had the doctor cut wider the patient might have lived longer.

Dr. W. I. Terry said that the autopsy demonstrated the fact that the liver was full of carcinomatous masses, and he can not believe that any further operation or wider cut could have been of any avail. Regarding the anastomosis, he thinks the button was a success in this case.

Dr. Carpenter called attention to a point in the technic, which was to remove as much of the lesser omentum as possible, because the circulation is up and through the lesser omentum.

Dr. Huntington said he was rather pessimistic regarding the possibility of a radical cure in these cases, because it is very seldom that the disease has not involved other organs. He recognizes the superior ability of one man over another in using the button, and thinks that when the reports are all in, an appalling list of tragedies will be found to be due to the button. Richardson prefers the suture, and has never used the button successfully. The matter must rest for a considerable time. The button can certainly be adjusted more rapidly, and will be used where haste is necessary.

Carcinoma of Breast.

Dr. T. W. Huntington also exhibited a breast removed recently. It showed a discrete carcinomatous map occupying nearly the center of the breast. This tumor was about the size of a lemon. It was quite movable and, externally, no axillary glands could be detected. A full Halsted operation was done. Upon entering the axilla a large number of infiltrated glands were uncovered.

Case of Leprosy.

Dr. Jos. G. Morrissey exhibited a boy 11 years of age who had leprosy. He was born in the Tahiti Islands. His father was French and his mother a native woman of French descent. There was no history of leprosy in the family. He came to San Francisco three months ago. with his father. He was first seen by Dr. C. F. Griffin, who reported the case to the health officer. He had several patches, on various parts of the body, of well-marked anesthesia, one spot alongside of the left eye, through which a pin could be passed without his feeling it. Both ears were involved, also the fingers; and the large toe of the left foot was half gone. The disease was of the nodular type. Lepra bacilli had been found, both in the blood and in the sections of tissue taken from the lesions. The diagnosis had been confirmed by Drs. Montgomery, Ophuls and Morrow. The boy's general health did not seem to be impaired, as he was quite active. The disease began about three years ago.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Prostatic Hypertrophy.

Dr. R. Guitéras, in his article on treatment of prostatic hypertrophy, in the *New York Medical Journal*, states that belladonna is the best antispasmodic, although codein and hyoscyamus are preferred by many. He recommends the following:

℞.	Tinct. belladonnæ	ʒii	8	
	Potassii acetatis	ʒiv	16	
	Aq. menthæ pip. q. s. ad	℥ii	64	

M. Sig.: One teaspoonful three times a day between meals.

Another prescription for the same purpose he advises as follows:

℞.	Codeinæ	gr. viii		5
	Tinct. belladonnæ	ʒiiss	10	
	Potassii acetatis	ʒiv	16	
	Aq. menth. pip. q. s. ad	℥ii	64	

M. Sig.: One teaspoonful three times a day in a glass of water.

In some cases, he states, it will be necessary to resort to a suppository at night in order to give the patients the desired relief. Under such circumstances the following is recommended:

℞.	Ext. belladonnæ			
	Morphinæ sulphatis, āā	gr. 1/4		015
	Cacao butter q. s.			

Hot rectal douches of saline solution before going to bed and the administration of some of the bladder antiseptics are also of benefit.

Acute Laryngitis in Children.

℞.	Apomorphinæ hydrochlor.	gr. 1/3		02
	Acidi hydrochlor. dil.	gtt. iii		19
	Syrupi senegæ	ʒv	20	

M. Sig.: One teaspoonful every hour.

Treatment of Subacute Laryngitis of Vocalists.

Faulkner, in *Clinical Ther.*, outlines the following treatment:

1. An aperient.
2. Laryngeal spray of 1 per cent. solution of cocain.
3. The following lozenges may be of use:

℞.	Morphinæ bimeconatis	gr. 1/100		0006
	Cocainæ hydrochloratis	gr. 1/125		0005
	Tinct. aconiti	m. 1/6		01
	Pulv. altheæ rad.	gr. ss		03

M. Ft. lozenge No. i. Sig.: One to be taken in the mouth frequently.

4. As a preparation for a vocal effort, after acute symptoms have subsided, strychnia—gr. 1/60 three times a day—is of service.

Pleurisy with Effusion in Children.

Widerhofer, in *Yeo's Man. of Ther.*, recommends the following:

℞.	Potassii acetatis	gr. xx-xl	1	33-2.66
	Syrupi simplicis	ʒiii	12	
	Infusi digitalis q. s. ad	℥iii	96	

M. Sig.: One teaspoonful every two hours.

Or,

℞.	Potassii acetatis	gr. xx-lx	1	33-4
	Syr. aurantii	ʒiii	12	
	Decoct. cinchonæ q. s. ad	℥iii	96	

M. Sig.: One teaspoonful every two hours.

As external application he recommends the following:

℞.	Iodi	gr. iss		09
	Potassii iodidi	ʒiiss	10	
	Glycerini	℥iss	48	

M. Ft. linimentum. Sig.: For external application once or twice daily.

Left Cecal Hernia.

Dr. John H. Gibbon read a paper entitled "Left Cecal Hernia, with Report of Two Cases." He believes that this condition occurs more frequently than has been supposed, since it has not been the practice to open the sac. More recently certain operators have met with the condition repeatedly. In the first case, the man suffered with hernia for years, and later strangulation occurred. On opening the sac both the cecum and ilium could be easily seen. The patient recovered from the operation, but later died, probably of heart disease.

The second patient was a laborer, 55 years of age, who had suffered from a hernia extending almost to the knee. Dr. W. W. Keen operated, by aid of spinal anesthesia. Two days afterward the man developed stricture of the urethra, and later died of symptoms of sepsis, probably of kidney origin. The speaker considers cecal hernia very rare in women, and the most frequent cause of the condition an abnormally long mesocolon.

Obstructive Jaundice.

Dr. John B. Deaver read a paper on "Mortality in Operations for Obstructive Jaundice." He enumerated the causes of the condition as outlined by Murchison and Osler. Peritonitis is not a common cause of death in obstructive jaundice. The effects of the bile salts on the blood seem to increase the tendency to excessive bleeding, and to secondary hemorrhage. He lost a case from secondary hemorrhage following an operation for this condition. To lessen the tendency toward this condition he gave calcium chlorid, but could not speak definitely as to its effects. Suprarenal extract in one case did good. Hemorrhage and shock are common causes of death. These facts seem to indicate that the sooner an operation is done the better will be the prognosis. It is better to open the abdomen and find nothing wrong than to wait until later and then find an irremediable condition.

Dr. J. H. Gibbon asked the speaker whether he had ever met with a case of acute dilatation of the stomach in these operations.

Dr. R. G. Le Conte asked whether he had ever tried gelatin to lessen the tendency to hemorrhage.

Dr. Deaver stated that when there is dilatation of the stomach it is the result of the general septic condition. He has not tried gelatin.

Enterectomy in Strangulated Hernia.

Dr. T. S. K. Morton reported "A Case of Strangulated Femoral Hernia; Herniotomy; Acute Obstruction Three Weeks Later; Enterectomy; Recovery." In this case taxis had been tried before the patient was seen by the speaker, but without result. He did herniotomy, and replaced the bowel. A few days later abdominal colic occurred, and three weeks later there were symptoms of obstruction. He opened the abdomen and found an obstruction. Enterectomy was done by means of the Downes forceps. About eight inches of the bowel was removed and the patient made a good recovery.

Dr. John B. Deaver stated that he had often thought that the white line, as found at the time of herniotomy, might be the subsequent seat of obstruction of the bowel, owing probably to cicatricial tissue formation at that spot.

Suppurating Hematocele.

Dr. George Erety Shoemaker read a paper entitled "Treatment of Suppurating Hematocele Following Extra-uterine Pregnancy." In doing this operation he prefers the abdominal route. Pelvic hematocele can, however, be best drained through the vagina.

CALIFORNIA ACADEMY OF MEDICINE.

Meeting held February 26.

Appendicitis During Typhoid.

Dr. Beverly MacMonagle reported two cases of appendicitis operated on during the course of typhoid fever. The first was in a young man of 18, who, at the end of the second week of a typical attack of typhoid, suddenly complained of a severe pain in the right iliac region, and the temperature rose to 105. The Doctor was called in consultation the same day, and found considerable general tenderness, decidedly increased in the right iliac region, with muscles tense to the point of spasm on slight pressure, and apparent increased dulness in the groin. Rectal examination showed decided tenderness in the rectovesical cul-de-sac, particularly on the right side. The spleen was enlarged, the liver dulness normal. A blood count showed a leucocytosis of 17,000. Abdominal section was determined on; the only question being between perforation and appendicitis. The appendix was removed. The temperature came down to 103 and the pulse to 110 the following day. The patient went through the usual course of typhoid to recovery. The anesthetic and operation did not seem to add any additional trials to his case.

The second case occurred in a man 27 years of age. Nineteen days from the commencement of his typhoid he had a chill, and began to vomit and suffer severe pain in the abdomen. Temperature went up to 105, pulse 156, respiration 38. The abdomen was tense and tender, with rigid muscles over the right iliac region. While he could not detect dulness, he thought he could feel some thickening over the appendix. Incision was made and the appendix removed. Temperature in twelve hours was 102, the bowels moved and the stools had the appearance of containing blood. The patient vomited a good deal and the pulse was not satisfactory. On the second day after operation vomiting ceased and the patient was more comfortable, the pulse and temperature much the same. The third day a blood count showed leucocytosis of 19,000, pulse and temperature were the same, and the bowels moved freely. On the fourth day the temperature was 104, pulse 142, respiration 34, with a slight chilly feeling, and some pain in the seat of operation. Examination showed pus in the abdominal wound, which was evacuated, when the temperature and pulse fell. After this the patient progressed very well, the abdominal incision discharging pus for twenty-two days, when it closed and convalescence was established.

Dr. W. W. Kerr said that the combination of the two diseases was by no means uncommon. He had had two such cases, one a perforation close to the end of the appendix, with ulceration extending down into the appendix itself. He thought it a question whether we should recommend operation as promptly as in cases where typhoid did not exist. The presence of typhoid should make us more cautious.

Dr. J. Henry Barbat said he was particularly interested in these reports because a man on whom he recently operated had typhoid fever nine months before. His attack then looked like appendicitis, but a diagnosis of typhoid was made. He never got entirely well, but had pain in the right side at times. Recently he had an attack of gall-stone colic, for which he operated, removing a small stone, and found the appendix very firmly bound down by adhesions, which made it very difficult of removal. It is reasonable to suppose that he had an appendicitis along with his typhoid.

Dr. T. W. Huntington said that the coexistence of the two diseases has long been recognized. There can be no question regarding the propriety of operating in these, for the patients stand operation very well. He considers the blood count of special value in determining the existence of appendicitis.

Dr. George M. Hughes said that patients having typhoid react well from operation. He has seen several operated on for perforation, and, where ether was used, the patients came off the table with better pulses than before. He thinks we should operate in all cases of appendicitis complicating typhoid. We may be in doubt as to whether pain is due to appendicitis or typhoid ulcer, but operation will add no danger for the patient, and it would be better to err on the safe side and operate.

Dr. MacMonagle said that this was the extent of his experience in such cases. The question was whether one should operate in cases in which the pain became very severe, with poor pulse, shallow respiration and vomiting. The question of perforation was left out, because the temperature went so high.

Carcinoma of the Pylorus and Stomach.

Dr. T. W. Huntington exhibited a specimen showing the result of an operation for carcinoma of the pylorus and of the stomach. On Aug. 5, 1900, pylorectomy and partial gastrectomy was performed upon a man 67 years old. At the time of operation the pylorus was almost entirely obstructed by the growth. After removal of the pylorus and a considerable portion of the stomach, the divided end of the duodenum was attached to the posterior wall of the stomach by a Murphy button. There was rapid recovery from the operation. For three months the patient gained perceptibly; his weight increased 35 pounds; he ate a promiscuous diet with relish. He then began to fail, with a recurrence of former symptoms, and died Dec. 24, 1900, nearly five months after the operation. At autopsy, there was extensive carcinomatous involvement of the stomach along the lesser curvature, and at the point of anastomosis, also of the liver and pancreas.

Dr. MacMonagle said that it was a question whether or not the doctor should have taken out more of the stomach. He has had one successful and one unsuccessful case. In his fatal one he had not taken out a sufficient number of glands. He thinks statistics show that the result is as good in gastroenterostomy as in total removal of the stomach. In this specimen of Dr. Huntington's the union showed that the stomach had attained its original condition of strength. Recurrence was beyond prevention.

Dr. Barbat said that in the majority of successful cases the anastomosis is made with the Murphy button; it saves time if properly applied, prevents leakage, and in general gives a better and safer result, and had the doctor cut wider the patient might have lived longer.

Dr. W. I. Terry said that the autopsy demonstrated the fact that the liver was full of carcinomatous masses, and he can not believe that any further operation or wider cut could have been of any avail. Regarding the anastomosis, he thinks the button was a success in this case.

Dr. Carpenter called attention to a point in the technic, which was to remove as much of the lesser omentum as possible, because the circulation is up and through the lesser omentum.

Dr. Huntington said he was rather pessimistic regarding the possibility of a radical cure in these cases, because it is very seldom that the disease has not involved other organs. He recognizes the superior ability of one man over another in using the button, and thinks that when the reports are all in, an appalling list of tragedies will be found to be due to the button. Richardson prefers the suture, and has never used the button successfully. The matter must rest for a considerable time. The button can certainly be adjusted more rapidly, and will be used where haste is necessary.

Carcinoma of Breast.

Dr. T. W. Huntington also exhibited a breast removed recently. It showed a discrete carcinomatous map occupying nearly the center of the breast. This tumor was about the size of a lemon. It was quite movable and, externally, no axillary glands could be detected. A full Halsted operation was done. Upon entering the axilla a large number of infiltrated glands were uncovered.

Case of Leprosy.

Dr. Jos. G. Morrissey exhibited a boy 11 years of age who had leprosy. He was born in the Tahiti Islands. His father was French and his mother a native woman of French descent. There was no history of leprosy in the family. He came to San Francisco three months ago. with his father. He was first seen by Dr. C. F. Griffin, who reported the case to the health officer. He had several patches, on various parts of the body, of well-marked anesthesia, one spot alongside of the left eye, through which a pin could be passed without his feeling it. Both ears were involved, also the fingers; and the large toe of the left foot was half gone. The disease was of the nodular type. Lepra bacilli had been found, both in the blood and in the sections of tissue taken from the lesions. The diagnosis had been confirmed by Drs. Montgomery, Ophuls and Morrow. The boy's general health did not seem to be impaired, as he was quite active. The disease began about three years ago.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Prostatic Hypertrophy.

Dr. R. Guitéras, in his article on treatment of prostatic hypertrophy, in the *New York Medical Journal*, states that belladonna is the best antispasmodic, although codein and hyoscyamus are preferred by many. He recommends the following:

℞. Tinct. belladonnæ ....ʒii 8|
Potassii acetatis ....ʒiv 16|
Aq. menthæ pip. q. s. ad..............℥ii 64|
M. Sig.: One teaspoonful three times a day between meals.

Another prescription for the same purpose he advises as follows:

℞. Codeinæ ....gr. viii |5
Tinct. belladonnæ ....ʒiiss 10|
Potassii acetatis ....ʒiv 16|
Aq. menth. pip. q. s. ad..............℥ii 64|
M. Sig.: One teaspoonful three times a day in a glass of water.

In some cases, he states, it will be necessary to resort to a suppository at night in order to give the patients the desired relief. Under such circumstances the following is recommended:

℞. Ext. belladonnæ
Morphinæ sulphatis, āā..........gr. 1/4 |015
Cacao butter q. s.
Hot rectal douches of saline solution before going to bed and the administration of some of the bladder antiseptics are also of benefit.

Acute Laryngitis in Children.

℞. Apomorphinæ hydrochlor..........gr. 1/3 |02
Acidi hydrochlor. dil................gtt. iii |19
Syrupi senegæ ....ʒv 20|
M. Sig.: One teaspoonful every hour.

Treatment of Subacute Laryngitis of Vocalists.

Faulkner, in *Clinical Ther.*, outlines the following treatment:

1. An aperient.
2. Laryngeal spray of 1 per cent. solution of cocain.
3. The following lozenges may be of use:

℞. Morphinæ bimeconatis ....gr. 1/100 |0006
Cocainæ hydrochloratis ....gr. 1/125 |0005
Tinct. aconiti ....m. 1/6 |01
Pulv. altheæ rad...................gr. ss |03
M. Ft. lozenge No. i. Sig.: One to be taken in the mouth frequently.

4. As a preparation for a vocal effort, after acute symptoms have subsided, strychnia—gr. 1/60 three times a day—is of service.

Pleurisy with Effusion in Children.

Widerhofer, in *Yeo's Man. of Ther.*, recommends the following:

℞. Potassii acetatis ....gr. xx-xl 1|33-2.66
Syrupi simplicis ....ʒiii 12|
Infusi digitalis q. s. ad..............℥iii 96|
M. Sig.: One teaspoonful every two hours.
Or,
℞. Potassii acetatis ....gr. xx-lx 1|33-4
Syr. aurantii ....ʒiii 12|
Decoct. cinchonæ q. s. ad............℥iii 96|
M. Sig.: One teaspoonful every two hours.

As external application he recommends the following:

℞. Iodi ....gr. iss |09
Potassii iodidi ....ʒiiss 10|
Glycerini ....℥iss 48|
M. Ft. linimentum. Sig.: For external application once or twice daily.

Treatment of Hemoptysis.

Dr. W. George Smith, as noted in *Ther. Gazette*, states that in an urgent case of hemoptysis, 1, the patient should be kept calm and the excitement of his friends quieted with a few judicious words by emphasizing the fact that hemorrhage per se is not a serious matter; 2, avoid irritation of the gastric ends of the vagus nerve. Therefore do not administer pieces of ice or cold drinks, as they irritate the gastric branches of the vagus, give rise to cough and thus aggravate the bleeding, as well as cause contractions of the stomach. On the other hand, give warm, mucilaginous drinks and place ice on the chest; 3, keep the patient quiet in mind and body; 4, give morphin hypodermically. The latter is the best thing of all; 5, relieve the bowels by magnesium sulphate or by calomel; 6, let diet be simple and nutritious, reduce the amount of liquid and give no alcohol.

For Cold in the Head.

The following powder will relieve the congestion and act as a palliative to the mucous membrane of the nose:

℞.	Menthol	gr. iii		20
	Acidi borici	ʒi	4	
	Bismuthi subcarb.	ʒiss	6	
	Benzoin	ʒiss	6	
	Sodii bicarb.	gr. x		66
	Magnesii carb.	gr. xv	1	
	Sacchari lactis	℥i	32	

M. Sig.: Use as an insufflation into the nose four or five times a day.

For the Cough in Phthisis.

According to the *St. Louis Med. Jour.*, Weisenburg employs with success the following combination in cough due to tubercular ulceration of the epiglottis:

℞.	Dionin hydrochlor.			
	Codeinæ hydrochlor., āā	gr. iss		10
	Cocainæ hydrochlor.	gr. iv		25
	Ammon. valer.			
	Aquæ amygdalæ amaræ, āā	ʒii	8	

M. Sig.: Fifteen drops on a lump of sugar three or four times a day. Allow the sugar to dissolve slowly in the back part of the pharynx.

Ichthyol in Treatment of Deep-Seated Inflammations.

W. T. Slevin, in *N. Y. Med. Jour.*, emphasizes the value of the following ointment in deep-seated, as well as superficial, inflammations:

℞.	Ichthyol			
	Plumbi iodidi, āā	gr. xlv	3	
	Ammonii chloridi	gr. x		66
	Petrolati q. s. ad	℥i	32	

M. Sig.: To be rubbed thoroughly upon the inflamed parts.

The Use of Normal Saline Solution.

The *Ther. Gazette* states that some of the conditions in which the normal saline solution is of value are: Hemorrhage, surgical shock, toxemia from sepsis or any of the infectious diseases, puerperal eclampsia, renal disease, diabetic coma, poisoning by the various alkaloids, snake poisoning, etc. In children so small a quantity as one or two ounces is sufficient, and four ounces will often be of value in adults. It is a noteworthy fact that the urinary flow may be three or four times as great as the quantity actually injected. The best place for the injection is in the lateral lumbar region. A very common fault is the employment of water not hot enough. The water may be kept at the proper temperature by coiling a section of the tube several times in a basin of very hot water, which may be renewed at times. The water as it is delivered to the patient should be from 105 to 106 F.

Parotitis (Mumps).

In children, the following combination renders good service in treatment of the febrile stage:

℞.	Liq. ammonii acetatis	℥ss	16	
	Spts. etheris nitrosi	ʒii	8	
	Aq. menthæ pip. q. s. ad	℥iii	96	

M. Sig: One teasponful every two or three hours for a child er five years of age.

Treatment of Epilepsy.

Collins, in the "System of Pract. Ther.," states that in some cases of epilepsy the bromids, if given in combination with an acid, are not so apt to derange digestion. He recommends the following combination:

℞.	Acidi hydrobrom. dil.	m. x		66
	Ferri bromidi	gr. i		06
	Potassii bromidi	gr. x		66
	Sodii salicylatis	gr. ii		12
	Spts. rectificat.			
	Glycerol pepsini, āā	m. x		66
	Ol. gaultheriæ	m. ss		03
	Liq. ammon. cit. (B. P.)	ʒss	2	

M. Sig.: At one dose. This may be doubled or tripled.

Peruol in Treatment of Scabies.

Richards Sachs, in *Deutsche Med. Woch.*, states that the best treatment consists in employing a preparation that will produce no bad effects upon the skin or other organs, that does not discolor the skin or clothes and one that has no odor. He claims that peruol has none of these disadvantages, which can not be claimed for many of the other preparations commonly used. Peruol, he states, will kill the acarus in thirty minutes. This preparation is composed of peruscabin (the principal active constituent of Peru balsam) one part, and oleum ricini three parts. Three applications should be given within thirty-six hours, and well rubbed in, when a cure is usually effected. Any eczema or dermatitis present is not rendered worse by the application of this preparation.

Treatment of Hemoglobinuria.

Dr. N. S. Davis, Jr., states that, when there is an excessive elimination of mineral salts by the urine and consequently a diminished amount in the blood, Robin advises a diet rich in such mineral matter and the administration of the following powder twice daily:

℞.	Sodii chloridi	gr. v		3
	Potassii chloridi	gr. ivss		26
	Sodii phosphatis	gr. i		06
	Potassii phosphatis	gr. iiss		15
	Calcii glycerophosphatis	gr. ss		03
	Magnesii glycerophosphatis	gr. 1/6		01
	Potassii sulphatis	gr. ss		03
	Ferri glycerophosphatis	gr. i		06
	Pulv. hemoglobin	gr. i		06

M. Ft. chartula No. i. Sig.: One such powder twice a day.

Treatment of Tinea Tonsurans.

Dr. Brown, in *The Post-Graduate*, recommends:

℞.	Acidi salicyl.	gr. xx	1	33
	Chrysarobin	gr. xx	1	33
	Ichthyol	ʒi	4	
	Lanolin			
	Vaselini, āā	℥ss	16	

M. Sig.: Shave the parts and rub it over the whole surface. At the end of three days the head should be washed and some emollient salve applied to check the dermatitis. In a few days the former salve may be re-applied. The treatment should be kept up for a month or six weeks.

Seborrheic Eczema.

Dr. Brown also states that resorcin and sulphur are the most valuable agents in treatment of seborrheic eczema. He recommends the following:

℞.	Hydrarg. chloridi corros.	gr. i		06
	Resorcin	ʒi	4	
	Chloralis hydratis	ʒi	4	
	Ol. ricini	gr. x		66
	Spts. vini	℥iv	128	

M. Ft. lotio. Sig.: Apply to the scalp once or twice daily.

In more severe grades, with redness and infiltration of the scalp, a pomade such as the following serves the purpose better:

℞.	Acidi salicyl.	gr. xv	1	
	Resorcin	gr. xxv	1	66
	Sulphuris sublim.	ʒi	4	
	Ung. aquæ rosæ	℥i	32	

M. Sig.: Apply locally.

Scrofulosis.

Chrystie, in "System of Pract. Ther.," places cod-liver oil first in the list of medicinal agents in treatment of scrofulosis. He recommends the following excellent emulsions:

R.	Olei morrhuæ	℥vi	192
	Olei gaultheriæ	ʒi	4
	Mucilag. tragacanthæ	℥ii	64
	Aq. aurantii flor. q. s. ad	℥xii	384

M. Sig.: From a dessertspoonful to a tablespoonful three times a day.

Or,

℞.	Ol. morrhuæ	℥vi	192
	Ol. gaultheriæ	ʒi	4
	Spts. chloroformi	ʒii	8
	Glycerini		
	Yolk of egg, āā	ʒv	20
	Aq. aurantii flor. q. s. ad	℥xii	384

M. Sig.: One dessertspoonful to a tablespoonful three times a day. The second mixture is not so thick as the first and is, for that reason, preferred.

Administration of Iodoform.

According to *Presse Med.*, Thibaut combines iodoform with equal parts of pulverized Ceylon cinnamon for external use or pills. As a salve he uses the following:

℞.	Iodoformi	gr. xv	1	
	Essentiæ cinnamomi Zeylanici	m. v		30
	Vaselini	ʒv	20	

M. Sig.: For local application.

Medicolegal.

Experiments in Nature of Hearsay Evidence.—The Supreme Court of Louisiana holds, in the case of Seibert vs. McManus, that experiments made in the absence of parties interested in the results thereof are, as evidence, in the nature of hearsay, and, if received, the facts and conditions under which they were made should be shown to have been identical with those of the case before the court.

Failure to Call Physicians as Witnesses.—It appeared from the testimony in the personal injury case of Vergin vs. the City of Saginaw, that two physicians made examinations of the plaintiff a short time after she claimed to have been injured. One of the physicians made two examinations, and the other made one. They were for the purpose of ascertaining her physical condition. She did not call these witnesses. The Supreme Court of Michigan holds that it was error to refuse to give the jury an instruction stating these facts, and the plaintiff's failure to produce these witnesses might be given such weight by the jury as the latter saw fit.

Can Not Examine Persons to Settle Disputes of Doctors.—The plaintiff in the case of French vs. the Brooklyn Heights Railroad Company, a man 70 years of age, was thrown down and sustained a painful injury to his side, by the sudden starting of one of the defendant's street cars, while he was attempting to board it. There was a conflict of evidence upon the question of whether at the time of the trial his side showed a depression at the point of contact, indicating a continuation of the difficulty. The trial court apparently found in his favor upon this point. It gave him a judgment for $400, and, taking this view of the case, the second appellate division of the Supreme Court of New York declares that it is unprepared to pronounce it excessive. Moreover, it holds that there was no error on the trial court in refusing to make examination of the plaintiff's person. Indeed, it holds that the defendant had no right to demand that the court examine the plaintiff to determine a dispute between opposing doctors. If there are any authorities in support of the contention that the trial court erred in refusing to inspect the plaintiff physically, it says that the defendant's counsel did not call the attention of the court to them, and, in the absence of such authorities, the judgment of the court below should be affirmed.

Liability for Delay in Delivery of Medicine.—On the appeal of the Pacific and Wells-Fargo Express Companies vs. Redman, the Court of Civil Appeals of Texas has reversed a judgment for $380.30 recovered by the latter party for damages for physical and mental pain suffered and for the retarding of her recovery by an unwarranted delay in the delivery of a package of medicine. This had been prescribed by her physician, and could not be procured at a nearer point than a town 23 miles or so distant, from whence it was ordered by telephone. But the order was sent by, and the medicine shipped to, a relative, without the agent of the express companies being notified for whom intended, although the agent knew of the relationship and had heard of the plaintiff's sickness. Now, such being the case, the court applies the rule that, in the absence of notice of the principal's connection with the contract, she can recover only such damages as her agent could have recovered in a suit brought in his own name. But such damages it holds she was entitled to, though not special damages, for a delay in the delivery of three days beyond the time the medicine should have been delivered. Nor, under the rule adopted in that state, does it consider that notice after the date of the contract of shipment would render the companies liable for special damages. Then, too, it suggests that on another trial, due consideration be given to the fact that the medicine could have been procured in a few hours, at small expense, by the use of a private conveyance, pointing out that a well-settled rule of law imposes upon persons injured the duty to exercise reasonable care to minimize the damages likely to result from the fault of another.

Proof of Account in Action Against Administrator.—In the case of Garwood vs. Schlichenmaier, administrator, the Court of Civil appeals of Texas has reversed a judgment for $150 for medical services. The plaintiff physician had testified, among other things, that he had treated the patient for epilepsy during a certain period of about two months, nearly every day, or sometimes every two or three days; that he wrote prescriptions for him frequently, and gave him medicine in his office. The court holds that this was inadmissible on account of being testimony with reference to a transaction with the intestate, within the meaning of the state statute providing that in an action against an administrator neither party shall testify as to any transaction with the deceased, unless called as a witness by the opposite party. In other words, it would seem that under such a statute a physician is incompetent to prove his own services as such to the deceased, against the representative. If, however, the performance of the services has been proved otherwise, when so proved, the plaintiff, the court says, it would seem, may testify as to the value. Nor does it consider than an account by a physician for his services is such a one as can be proved under the provisions of a statute making a verified open account prima facie evidence of the debt. The word "account" in that connection, it holds, applies to transactions between persons in which, by sale upon the one side and purchase upon the other, the title to personal property is passed from one to the other, and the relation of debtor and creditor is thereby created by general course of dealing. So, it holds that the only purpose for which a physician's account is admissible in evidence in such a case as this is to show that it has been properly verified as a claim against the estate of the deceased, and that it has been rejected by the administrator, and that it is error to admit it in evidence for any other purpose.

Medical Examiners by Courtesy—Use of Narcotics.—The Court of Civil Appeals of Texas says, in National Fraternity vs. Karnes, that the medical examiner is regarded as the agent of the insurer, save where it appears that he colludes with the insured to defraud the company. But in this case it was the medical examiner of the insurer who wanted to be insured, and in company with the organizer of the local lodge went to the office of another physician, taking with him his answers already written out and signed. As to what then occurred the testimony of that other physician was such as to

Treatment of Hemoptysis.

Dr. W. George Smith, as noted in *Ther. Gazette*, states that in an urgent case of hemoptysis, 1, the patient should be kept calm and the excitement of his friends quieted with a few judicious words by emphasizing the fact that hemorrhage per se is not a serious matter; 2, avoid irritation of the gastric ends of the vagus nerve. Therefore do not administer pieces of ice or cold drinks, as they irritate the gastric branches of the vagus, give rise to cough and thus aggravate the bleeding, as well as cause contractions of the stomach. On the other hand, give warm, mucilaginous drinks and place ice on the chest; 3, keep the patient quiet in mind and body; 4, give morphin hypodermically. The latter is the best thing of all; 5, relieve the bowels by magnesium sulphate or by calomel; 6, let diet be simple and nutritious, reduce the amount of liquid and give no alcohol.

For Cold in the Head.

The following powder will relieve the congestion and act as a palliative to the mucous membrane of the nose:

℞.	Menthol	gr. iii		20
	Acidi borici	ʒi	4	
	Bismuthi subcarb.	ʒiss	6	
	Benzoin	ʒiss	6	
	Sodii bicarb.	gr. x		66
	Magnesii carb.	gr. xv	1	
	Sacchari lactis	℥i	32	

M. Sig.: Use as an insufflation into the nose four or five times a day.

For the Cough in Phthisis.

According to the *St. Louis Med. Jour.*, Weisenburg employs with success the following combination in cough due to tubercular ulceration of the epiglottis:

℞.	Dionin hydrochlor.			
	Codeinæ hydrochlor., āā	gr. iss		10
	Cocainæ hydrochlor.	gr. iv		25
	Ammon. valer.			
	Aquæ amygdalæ amaræ, āā	ʒii	8	

M. Sig.: Fifteen drops on a lump of sugar three or four times a day. Allow the sugar to dissolve slowly in the back part of the pharynx.

Ichthyol in Treatment of Deep-Seated Inflammations.

W. T. Slevin, in *N. Y. Med. Jour.*, emphasizes the value of the following ointment in deep-seated, as well as superficial, inflammations:

℞.	Ichthyol			
	Plumbi iodidi, āā	gr. xlv	3	
	Ammonii chloridi	gr. x		66
	Petrolati q. s. ad	℥i	32	

M. Sig.: To be rubbed thoroughly upon the inflamed parts.

The Use of Normal Saline Solution.

The *Ther. Gazette* states that some of the conditions in which the normal saline solution is of value are: Hemorrhage, surgical shock, toxemia from sepsis or any of the infectious diseases, puerperal eclampsia, renal disease, diabetic coma, poisoning by the various alkaloids, snake poisoning, etc. In children so small a quantity as one or two ounces is sufficient, and four ounces will often be of value in adults. It is a noteworthy fact that the urinary flow may be three or four times as great as the quantity actually injected. The best place for the injection is in the lateral lumbar region. A very common fault is the employment of water not hot enough. The water may be kept at the proper temperature by coiling a section of the tube several times in a basin of very hot water, which may be renewed at times. The water as it is delivered to the patient should be from 105 to 106 F.

Parotitis (Mumps).

In children, the following combination renders good service in treatment of the febrile stage:

℞.	Liq. ammonii acetatis	℥ss	16	
	Spts. etheris nitrosi	ʒii	8	
	Aq. menthæ pip. q. s. ad	℥iii	96	

M. Sig: One teaspoonful every two or three hours for a child over five years of age.

Treatment of Epilepsy.

Collins, in the "System of Pract. Ther.," states that in some cases of epilepsy the bromids, if given in combination with an acid, are *not* so apt to derange digestion. He recommends the following combination:

℞.	*Acidi hydrobrom. dil.*	m. x		66
	Ferri bromidi	gr. i		06
	Potassii bromidi	gr. x		66
	Sodii salicylatis	gr. ii		12
	Spts. rectificat.			
	Glycerol pepsini, āā	m. x		66
	Ol. gaultheriæ	m. ss		03
	Liq. ammon. cit. (B. P.)	ʒss	2	

M. Sig.: At one dose. This may be doubled or tripled.

Peruol in Treatment of Scabies.

Richards Sachs, in *Deutsche Med. Woch.*, states that the best treatment consists in employing a preparation that will produce no bad effects upon the skin or other organs, that does not discolor the skin or clothes and one that has no odor. He claims that peruol has none of these disadvantages, which can not be claimed for many of the other preparations commonly used. Peruol, he states, will kill the acarus in thirty minutes. This preparation is composed of peruscabin (the principal active constituent of Peru balsam) one part, and oleum ricini three parts. Three applications should be given within thirty-six hours, and well rubbed in, when a cure is usually effected. Any eczema or dermatitis present is not rendered worse by the application of this preparation.

Treatment of Hemoglobinuria.

Dr. N. S. Davis, Jr., states that, when there is an excessive elimination of mineral salts by the urine and consequently a diminished amount in the blood, Robin advises a diet rich in such mineral matter and the administration of the following powder twice daily:

℞.	Sodii chloridi	gr. v		3
	Potassii chloridi	gr. ivss		26
	Sodii phosphatis	gr. i		06
	Potassii phosphatis	gr. iiss		15
	[illegible]	gr. ss		03
	[illegible]	gr. 1/6		01
	Potassii sulphatis	gr. ss		03
	Ferri glycerophosphatis	gr. i		06
	Pulv. hemoglobin	gr. i		06

M. Ft. chartula No. i. Sig.: One such powder twice a day.

Treatment of Tinea Tonsurans.

Dr. Brown, in *The Post-Graduate*, recommends:

℞.	Acidi salicyl.	gr. xx	1	33
	Chrysarobin	gr. xx	1	33
	Ichthyol	ʒi	4	
	Lanolin			
	Vaselini, āā	℥ss	16	

M. Sig.: Shave the parts and rub it over the whole surface. At the end of three days the head should be washed and some emollient salve applied to check the dermatitis. In a few days the former salve may be re-applied. The treatment should be kept up for a month or six weeks.

Seborrheic Eczema.

Dr. Brown also states that resorcin and sulphur are the most valuable agents in treatment of seborrheic eczema. He recommends the following:

℞.	Hydrarg. chloridi corros.	gr. i		06
	Resorcin	ʒi	4	
	Chloralis hydratis	ʒi	4	
	Ol. ricini	gr. x		66
	Spts. vini	℥iv	128	

M. Ft. lotio. Sig.: Apply to the scalp once or twice daily.

In more severe grades, with redness and infiltration of the scalp, a pomade such as the following serves the purpose better:

℞.	Acidi salicyl.	gr. xv	1	
	Resorcin	gr. xxv	1	66
	Sulphuris sublim.	ʒi	4	
	Ung. aquæ rosæ	℥i	32	

M. Sig.: Apply locally.

Scrofulosis.

Chrystie, in "System of Pract. Ther.," places cod-liver oil first in the list of medicinal agents in treatment of scrofulosis. He recommends the following excellent emulsions:

R.	Olei morrhuæ	℥vi	192
	Olei gaultheriæ	ʒi	4
	Mucilag. tragacanthæ	℥ii	64
	Aq. aurantii flor. q. s. ad	℥xii	384

M. Sig.: From a dessertspoonful to a tablespoonful three times a day.

Or,

℞.	Ol. morrhuæ	℥vi	192
	Ol. gaultheriæ	ʒi	4
	Spts. chloroformi	ʒii	8
	Glycerini		
	Yolk of egg, āā	ʒv	20
	Aq. aurantii flor. q. s. ad	℥xii	384

M. Sig.: One dessertspoonful to a tablespoonful three times a day. The second mixture is not so thick as the first and is, for that reason, preferred.

Administration of Iodoform.

According to *Presse Med.*, Thibaut combines iodoform with equal parts of pulverized Ceylon cinnamon for external use or pills. As a salve he uses the following:

℞.	*Iodoformi*	*gr.* xv	1	30
	Essentiæ cinnamomi Zeylanici	m. v		
	Vaselini	ʒv	20	

M. Sig.: For local application.

Medicolegal.

Experiments in Nature of Hearsay Evidence.—The Supreme Court of Louisiana holds, in the case of Seibert vs. McManus, that experiments made in the absence of parties interested in the results thereof are, as evidence, in the nature of hearsay, and, if received, the facts and conditions under which they were made should be shown to have been identical with those of the case before the court.

Failure to Call Physicians as Witnesses.—It appeared from the testimony in the personal injury case of Vergin vs. the City of Saginaw, that two physicians made examinations of the plaintiff a short time after she claimed to have been injured. One of the physicians made two examinations, and the other made one. They were for the purpose of ascertaining her physical condition. She did not call these witnesses. The Supreme Court of Michigan holds that it was error to refuse to give the jury an instruction stating these facts, and the plaintiff's failure to produce these witnesses might be given such weight by the jury as the latter saw fit.

Can Not Examine Persons to Settle Disputes of Doctors.—The plaintiff in the case of French vs. the Brooklyn Heights Railroad Company, a man 70 years of age, was thrown down, and sustained a painful injury to his side, by the sudden starting of one of the defendant's street cars, while he was attempting to board it. There was a conflict of evidence upon the question of whether at the time of the trial his side showed a depression at the point of contact, indicating a continuation of the difficulty. The trial court apparently found in his favor upon this point. It gave him a judgment for $400, and, taking this view of the case, the second appellate division of the Supreme Court of New York declares that it is unprepared to pronounce it excessive. Moreover, it holds that there was no error on the trial court in refusing to make examination of the plaintiff's person. Indeed, it holds that the defendant had no right to demand that the court examine the plaintiff to determine a dispute between opposing doctors. If there are any authorities in support of the contention that the trial court erred in refusing to inspect the plaintiff physically, it says that the defendant's counsel did not call the attention of the court to them, and, in the absence of such authorities, the judgment of the court below should be affirmed.

Liability for Delay in Delivery of Medicine.—On the appeal of the Pacific and Wells-Fargo Express Companies vs. Redman, the Court of Civil Appeals of Texas has reversed a judgment for $380.30 recovered by the latter party for damages for physical and mental pain suffered and for the retarding of her recovery by an unwarranted delay in the delivery of a package of medicine. This had been prescribed by her physician, and could not be procured at a nearer point than a town 23 miles or so distant, from whence it was ordered by telephone. But the order was sent by, and the medicine shipped to, a relative, without the agent of the express companies being notified for whom intended, although the agent knew of the relationship and had heard of the plaintiff's sickness. Now, such being the case, the court applies the rule that, in the absence of notice of the principal's connection with the contract, she can recover only such damages as her agent could have recovered in a suit brought in his own name. But such damages it holds she was entitled to, though not special damages, for a delay in the delivery of three days beyond the time the medicine should have been delivered. Nor, under the rule adopted in that state, does it consider that notice after the date of the contract of shipment would render the companies liable for *special damages*. Then, too, it suggests that on another trial, due consideration be given to the fact that the medicine could have been procured in a few hours, at small expense, by the use of a private conveyance, pointing out that a well-settled rule of law imposes upon persons injured the duty to exercise reasonable care to minimize the damages likely to result from the fault of another.

Proof of Account in Action Against Administrator.—In the case of Garwood vs. Schlichenmaier, administrator, the Court of Civil appeals of Texas has reversed a judgment for $150 for medical services. The plaintiff physician had testified, among other things, that he had treated the patient for epilepsy during a certain period of about two months, nearly every day, or sometimes every two or three days; that he wrote prescriptions for him frequently, and gave him medicine in his office. The court holds that this was inadmissible on account of being testimony with reference to a transaction with the intestate, within the meaning of the state statute providing that in an action against an administrator neither party shall testify as to any transaction with the deceased, unless called as a witness by the opposite party. In other words, it would seem that under such a statute a physician is incompetent to prove his own services as such to the deceased, against the representative. If, however, the performance of the services has been proved otherwise, when so proved, the plaintiff, the court says, it would seem, may testify as to the value. Nor does it consider than an account by a physician for his services is such a one as can be proved under the provisions of a statute making a verified open account prima facie evidence of the debt. The word "account" in that connection, it holds, applies to transactions between persons in which, by sale upon the one side and purchase upon the other, the title to personal property is passed from one to the other, and the relation of debtor and creditor is thereby created by general course of dealing. So, it holds that the only purpose for which a physician's account is admissible in evidence in such a case as this is to show that it has been properly verified as a claim against the estate of the deceased, and that it has been rejected by the administrator, and that it is error to admit it in evidence for any other purpose.

Medical Examiners by Courtesy—Use of Narcotics.—The Court of Civil Appeals of Texas says, in National Fraternity vs. Karnes, that the medical examiner is regarded as the agent of the insurer, save where it appears that he colludes with the insured to defraud the company. But in this case it was the medical examiner of the insurer who wanted to be insured, and in company with the organizer of the local lodge went to the office of another physician, taking with him his answers already written out and signed. As to what then occurred the testimony of that other physician was such as to give the impression that there was really no medical examination, and that he treated the matter and signed the certificate as a mere act of accommodation for a brother physician, relying on the latter's being a physician himself, and understanding all the facts. In other words, that he in fact, and as an act of courtesy to his brother physician, gave him the benefit of his signature, for the purposes of the insurance, without any examination. Now, the court holds that the fraternity became bound, under the circumstances, by the information which the second physician possessed at the time he recommended the other as by information possessed by an agent. But, inasmuch as it is the established rule in that state that the agent's knowledge must have been obtained in the transaction of the principal's business to be imputed to the principal, it holds that the fraternity would not be charged with facts in the knowledge of the second physician or temporary medical examiner unless they were disclosed to him by the examination. Another point of interest in this case is with reference to the construction to be put upon the question: "Do you now, or have you ever used opium or other narcotics?" The answer was "No," and the court holds that the term "use" in this contract was correctly construed to have reference to a use which amounted to a custom or habit. Then, keeping this definition in mind, the court holds that, the answers having been warranted to be true, if this one was false it would invalidate the insurance, even if made in good faith, or through mistake, or by inadvertence, as well as if made intentionally.

AMERICAN.

1. **Yellow Fever.**—Carter thinks that the incubation period of yellow fever may be ranged between three and nine days, the shortest recorded in his notes being three days and the longest eight and one-fourth. He does not claim that cases of longer or shorter incubation may not occur, but the above limitations apparently include the average.

2. **Bottini's Operation.**—Bangs gives his experience with the Bottini operation, claiming that it cures or improves a large proportion of cases without serious risk and with the minimum of detention. The patient should be prepared for this operation as carefully and thoroughly as for any other, and the anesthetic should be chosen with judgment. Local anesthesia is usually accompanied with more or less pain during the operation. One symptom that follows the operation is frequent urination, and fever is a condition also to be expected. The post-operative period is more nearly three weeks than two. Some patients may be allowed to sit up at the end of a week, but should not resume their ordinary mode of life for at least two weeks. The after-treatment is as important as any part of the operation. Incontinence of urine has followed two of his cases. He reports a case and calls attention to the following points of technique which it has taught him: "1. That the flow of electricity must be maintained to a degree which will keep the blade at white heat. 2. That in measuring a given case for the length of the incisions, allowance must be made for the action of the galvanic cautery beyond the distance at which the knife shall actually penetrate. 3. That the operation must be done with great slowness, in order to prevent hemorrhage and to get the best results."

3. **Gastric Ulceration.**—After a review of the history of the operation for gastric ulceration, Heineman discusses the pathology, and the etiology, in regard to which point he discredits the hyperacidity theory, the clinical history, differential diagnosis, and prognosis. He believes that medical treatment should be tried unless the hemorrhages are repeated and a count of red blood globules shows a serious diminution in their number. It should include absolute physical rest of body and stomach, alimentation being exclusively rectal for three or four weeks. The surgical treatment, however, should be thought of and preparations made for it if necessary. The method of procedure of Cazin promises the best results; inversion of the gastric mucous membrane, careful absorption of the mucous by means of sterilized gauze and minute search for the seat of ulceration should be made.

4. **Acute Serofibrinous Pleurisy.**—Nammack thinks that perhaps we have gone too far in our fearlessness of tapping for pleurisy. He has been in the habit of teaching, in his clinics, that chest-tapping should be performed for serofibrinous pleurisy for three indications: 1. When life is directly threatened or endangered by asphyxia from compression, or by cardiac weakness. 2. When fluid has arisen to the third interspace in front, since we find that effusions of this size rarely disappear spontaneously. 3. In all lesser effusions when spontaneous absorption is unduly delayed. When these are not present we should think more of medical treatment, including local applications of guaiacol, or iodin when guaiacol has a too pronounced effect on the heat-regulating and vasomotor centers; mild cathartics, limitation of ingested liquids, and the consumption of as much table salt as the patient can be induced to take. While there are other conditions than the effusion in connection with pleurisy, this is the special point referred to here.

5. **Urinary Hemorrhage.**—Wiener discusses the subject of blood in the urine, with special reference to the diagnosis of its source, and gives a tabulated statement of the symptoms of hematuria from its pathologic conditions. In case of urethral hemorrhage it will continue without regard to the act of urination. If the hemorrhage is from the prostate, it usually occurs in middle to old age. The symptoms are absent in the early stages, the frequency of urination is increased both day and night, pain is usually absent, the clot usually precedes a free flow of blood, the condition is somewhat relieved by rest and there is usually cystitis with later pyelonephritis. If due to stone in the bladder, it occurs usually in childhood or adult life. The urination is involuntarily arrested; the symptoms are those of cystitis. The urination is markedly increased during the day, and there is pain in the glans, even after urination. The bleeding is most profuse at night and is much relieved by rest. The other organs are usually normal. If from vesical tuberculosis, it generally occurs in early life. The urination is voluntarily arrested, pain in the glans ceases after urination, the frequency is increased both day and night and not relieved by rest. The blood is bright, and is sudden in its appearance. The bleeding is transitory; usually a few drops at night. The prostate, seminal vesicle and epididymis are often involved in the general disease. If from tumor of the bladder, it occurs usually at an advanced age, symptoms are often absent, frequency of urination may not be increased, pain is unusual, bleeding is intermittent, often nocturnal and profuse. It is not influenced by rest and occurs mostly at the end of urination. The other organs are usually normal. Stone in the kidney usually occurs in adults about 40 years of age. Pyelitis is a late complication. Urination is relieved by rest, and is increased by exercise. Severe repeated colics occur. The bleeding is rarely profuse, may appear and disappear suddenly and is almost completely precipitated on standing. In the case of tuberculosis of the kidney, the patient is usually a young adult in poor general condition. The frequency of urination is marked both day and night; severe pain is felt, bleeding may be absent for long periods, and is usually of slight amount. It is not influenced by rest. The blood is intimately mixed in the urine and not completely precipitated. Pyelitis exists, spreading to the ureter and bladder. In case of tumor of the kidney, carcinoma is the type in advanced age; sarcoma may occur early. The symptoms are those of abdominal tumor. The frequency of urination is not markedly increased. Renal colic due to clot in the ureter is a symptom. The bleeding is profuse, often most at night and is not relieved by rest. The blood is very intimately mixed in the urine and not completely precipitated. The other organs are generally normal. The conditions that may lead to error in diagnosis are hemoglobinuria, drug intoxication from turpentine, carbolic acid, sulphonal, etc.: certain kinds of foods may cause hematuria, such as rhubarb, strawberries, and gooseberries, and the menstrual blood may some times get into the urine and cause errors of diagnosis. Hemoglobinuria may be readily recognized by the color, or absence of blood cells. The spectroscope may be of use, showing the characteristic dark bands between the Fraunhofer lines D and E. Wiener thinks that perhaps we are too prone in this age to lay aside old methods for new ones, and the object of his paper is to show how, in many cases, the diagnosis may be made out without the use of complicated apparatus.

8. **Ichthyol.**—Slevin recommends the following formula to be applied by rubbing upon the inflamed parts:

R.	Ichthyol	gr. 45
	Lead Iodid	gr. 45
	Ammonium chlorid	gr. 10
	Petrolatum, enough to make	1 ounce

He reports three cases of inflammatory diseases in which it was applied with benefit.

9. **Resorcin as Preservative for Suprarenal Extract.**—Resorcin has been found by Oppenheimer to prevent the putrefactive changes which take place in suprarenal extract on account of the large amount of animal matter present and at the same time does not impair its efficiency. It has been his habit to add 60 gr. of good dessiccated extract to one ounce of a 1 per cent. resorcin solution. The quantity for daily use is filtered, and he finds that as a hemostatic and vasomotor constrictor this combination is of great service.

10. **Malignant Disease of the Larynx.**—Thyreotomy, by Prof. J. N. Mackenzie's new operation, is questioned by Waggett as not yet having been sufficiently tried to justify all the claims that are made in its favor. The methods at present employed by Semon, Butlin, and others have yielded such brilliant results that he thinks it is absurd to sweep it aside as discredited.

11. **Turbinotomy.**—Boylan has operated in sixty-four cases for removal of the lower portion of the turbinated body with the cold snare. He thinks this method preferable to the use of the saw and scissors, excepting where excessive indurations indicate thickened bone. In order to meet the objection of the slipping forward of the loop over the medial surface and lower margin of the body, he fixes the end of the loop by burying the

point of a fine tenaculum, the hook of which forms a right angle, into the lower margin of the turbinated body at the point of operation, carrying the loop over its handle into the meatus, adjusting it so that it passes behind and is held in place at the back of the hook. In this way it is possible to entirely control the removal of the amount of tissue required. Amputation can be done with accuracy. Finding that the point of the hook was at times caught in the loops, he afterward had this bent to an angle somewhat more acute than a right angle, to avoid this. During the manipulation the snare should be pressed firmly backward and upward, so that the loop is drawn from above rather than from in front.

12. **Pseudocyesis and Myxedema.**—Noticing first the occasional difficulty of recognizing the genuine condition and the medicolegal importance of spurious pregnancy, Davis reports several cases of the latter condition, one of them a neurotic patient apparently recovered from myxedema.

13. **Morphin.**—Reichert reports experiments on the action of morphin on heat production, heat dissipation and body temperature, with special reference to the effect of the depression produced by the drug upon the internal secretions. He claims that the profound depression of general metabolism thus produced by even non-fatal doses, together with the probable involvement of the processes concerned in the internal secretions and in repair and their consequent affection, may be considered among the important factors in the question of the treatment of morphin poisoning, and that probably future research will show that we have in this depression an agent in explaining a part at least of the play of certain physiologic antidotes, as well as the non-effectiveness of others, such at atropin, which on theoretical ground would be supposed to be effective. Also, if a means be found to restore the normal processes of secretion and repair, the counteraction of the direct action of morphin upon the metabolic process as well as the respiration will probably be accomplished with less difficulty than heretofore.

14. **Paresis Simulating Brain Tumor.**—Sinkler reports a couple of cases in which the symptoms strongly indicated brain tumors in the earlier phases of the disease, the patient later becoming clearly a paretic. He calls attention to these facts as indicating possible errors of diagnosis in early paresis.

19. **Albuminous Nutrition.**—Bernheim's article is largely the notice of an article by Finkler, who describes a form of albumin food which can be given in many conditions where a special food is required. He gives its advantages as follows: This food is an almost chemically pure albumin of animal and vegetable origin in the average proportion of normal daily diet. It is a slightly brownish powder, odorless and tasteless. It is sterile and can be kept for any length of time, with no deterioration. The plain preparation is not soluble in water, but is readily accessible to the secretory juices of the alimentary apparatus. The iron mixture is soluble. It is resorbable to an extent of more than 90 per cent. of its weight when taken into the body. It can be eaten with food, by itself, or added and mixed with any other food, without changing the taste or flavor. On account of its high degree of resorbability, it is an exceedingly cheap proteid food for the sick as well as the healthy, and must become an ideal albuminous nourishment for the soldier and travellers on account of its small bulk and absolute digestibility. It gives excellent results in all cases of mal-nutrition from insanity, anemia, consumption, gastric and intestinal diseases, acute infection, in convalescence and in all cases of disturbed metabolism. Though insoluble in water, it does not lose any of its good qualities and is preferable to soluble and predigested foods in most cases. He thinks that it is the food of the future, like other artificially manufactured foods, when the population has increased to such a degree that the necessities of life will have to be manufactured. He gives his experience with this albuminous food in cases of healthy persons, and also in invalids.

21. **The Consumptive Poor.**—Knopf's paper is a plea for the sanitarium treatment of the consumptive poor.

22. **Pericystitic Strands.**—While examining patients with the cystoscope, Bierhoff's attention was called to a change similar to columnated structure of the bladder, but differing from it in that it occurred in limited portions of the bladder wall and in female patients who had not suffered from any obstruction to urination, but had in most cases at some previous period suffered from parametritis or allied conditions. Following the suggestion of Dr. Knorr, he examined all cases with previous history of such uterine conditions, as to their vesical symptoms. Of 443 cases, histories of parametritis, etc., were obtainable in 214; symptoms referable to urinary organs in 264; pericystic strands present in 136; no other discoverable cause of symptoms than perivesical changes in 8; perivesical changes, as accessory cause in 67. These pericystitic strands, imitating in some respects the columnated structure of the bladder, are, according to the author, due to uterine inflammations, which extend and involve the walls of the bladder, and the fibrinous strands resulting from the organization and contraction of the inflammatory exudate, pull upon parts of the bladder wall. The characteristic appearance is the presence, over parts of these walls, of sharp, scar-like formations which rise, to a greater or less extent, above the surrounding surface, having a yellowish-white color, and tend to fimbriate at the end. Besides the columnar bladder structures, the contractions of the bladder muscle might be confused with these, but when these occur they appear and then disappear over the entire field of vision and are thus differentiated from the condition described. The recent cases can be treated by measures to promote resorption of the exudate. The later changes are of interest chiefly because they may exert an influence as complicating factors or disturbances of urination or produce vesical hyperesthesia.

23. **The Prevention of Insanity.**—The principal points in Coe's article are the regulation, under medical advice, of marriage and reproduction by persons who have strong family taints of insanity, and the proper education and regulation of life in such cases.

24. **The Tonometer.**—Shaw considers Gaertner's tonometer as a valuable method of ascertaining the degree of blood pressure. The description of the instrument and its use was given in an earlier paper by the author abstracted in The Journal vol. xxxiv p. 415 from the *Medical Record* Feb. 3, 1900.

27. **Carcinoma of the Extremity of the Common Bile Duct.**—After reporting a case of carcinoma involving the end of the common duct, with autopsy, Edes discusses the frequency of these conditions. He thinks that undoubtedly they are more common than often supposed, and quotes the references in the Index Catalogue in support of this view. He thinks that while probably gall-stones play an important part in the etiology of carcinoma of the gall-bladder, we must look elsewhere for the local irritation necessary to set up the same growth in the ducts. The diagnosis is not entirely certain or satisfactory, but is not absolutely impossible. The important point is to determine the exact location of the growth and this can not be done without operation. The possibility of relief by operation is noticed, but the prospects are apparently not usually encouraging by the time the diagnosis is established.

28. **Diphtheria Diagnosis.**—Methods in the Boston Board of Health's pathologic laboratory are described by Hill. A summary of the examinations is given in a tabulated form, and the interpretation of results detailed. The presence of diphtheria bacilli is used as a sort of toxin indicator and the positive diagnosis based upon it. The meaning of the negative report, however, was not considered absolute, and a "no growth" report was used when for any technical reason the examination of the cultures was a failure. He found diphtheria bacilli in about 60 to 70 per cent. of cases clinically designated as diphtheria, and in about 10 or 11 per cent. of those diagnosed as non-diphtheria. The positive report from swab examinations was of the same significance as the positive one from cultures, while the negative report is absolutely meaningless. Since, however, the positive swab results save from fifteen to twenty-four hours of waiting for the results of cultures, it was worth while to employ it even if positive results could only be obtained in 50 per cent. of the cases. The release from isola-

tion in diphtheria is a matter not so easy of decision. It was found that release on one negative culture allowed 30 per cent. of the patients to go out of isolation, while the bacteria are still present, while with two or more consecutive negative cultures only about 1 to 3 per cent. of those released will be still infected. To make sure of absolute non-infection by requiring three consecutive cultures involved so much additional trouble that it was found impracticable.

30. **Infantile Convulsions.**—From the records of the Boston Children's Hospital, Bullard and Townsend find that 1 per cent. of the children applying for treatment came for convulsions; 10 per cent. between 5 and 12 years of age gave a history of convulsions. Cases that appear to be due to some manifest reflex cause may turn out to be true epilepsy. Other cases, where the attacks occur frequently and without apparent cause, may suddenly recover, at least for a considerable period. Children who have had convulsions may be strong and free from nervous tendencies, though the proportion of those who have such nervous tendencies seems to be greater than in those who have not had convulsions.

35.—See abstract in The Journal xxxv, p. 1048.

38. **Adenoids.**—The occasional failure of the disappearance of unpleasant symptoms due to adenoids after their removal, is remarked upon by Huber, who enumerates the possible causes of mouth breathing, such as diphtheria, nasal catarrh, foreign bodies, inflammatory conditions in the nose, traumas, neoplasms, etc. The methods he suggests in these cases are examination for nasal obstruction, the use of boric acid, operation for deflected septum, curetting, and teaching the children to breathe through their noses.

44. **Paralysis Agitans.**—In the conclusion of his paper Taylor says: "I feel myself warranted in expressing the conviction that in most forms of tremor, whatsoever their cause, we may hope to obtain fair amelioration of symptoms, and it may be in some instances, a cure, by carefully regulated and systematized movements. These should be such as shall reestablish the largest degree of elasticity in the tissues which have suffered contractures. They should always include passive extensions and flexions, followed by active repetitions of these acts. The most important movements to overcome the milder forms of tremor, as the senile form, are slow, full forcible extensions. An important part of the treatment is the attainment of normal attitudes. Along with this should be continued conscientious efforts on the part of the patient to acquire full thoracic capacity, and as much elasticity of the lungs as possible. To regain and maintain health and activity in chronic conditions of almost any sort, is conditional upon a fair respiratory capacity constantly exercised."

51. **Chronic Maxillary Empyema.**—Winslow reviews the opinions of authorities, reports cases of antral empyema, and emphasizes the following points: 1. That antral empyema is not only not always, but is not generally, due to dental disease, the contrary view being based upon clinical rather than anatomical observation. 2. Its frequency and the necessity for systematic examination by multiple proof-puncture in suspected cases; latent empyema would thus not be allowed to exist until it makes itself manifest by caries and the apparent causal relation between the two would become much less notable. 3. Unless evidently of dental origin, antral empyema should be treated through the nose until it is certain that complications exist, and we then should investigate through a large opening in the facial wall. 4. The alveolar opening should be reserved for those cases of undoubted dental origin, and for those who refuse the radical operation. Even then the cases should not be referred entirely to the dentist, for they usually take no account of nasal conditions.

60. **Gastric Carcinoma.**—McCaskey reviews the methods of diagnosis of gastric carcinoma with a view to its early operation. The chief symptoms are anorexia, vomiting, pain, hemorrhage and obstinate constipation. However, these are not all constant. The condition of the blood is not different from that of any other serious nutritional disease. Peptonuria, if suppurative processes are to be excluded, is of decided value as indicating the absorption of peptones from an ulcerated surface in the gastro-intestinal tract. He mentions his cardiameter, described before, by which he can determine the presence or absence of ptosis or ectasia. Of the chemical and microscopic signs, the absence of HCl has been proven to be a non-characteristic symptom. Lactic acid has also no pathognomonic significance. Microscopic evidences, however, are of great value, and may be obtained from washings of the fasting stomach or by using the stomach-tube as a sort of curette. Atypical mitosis at present is not regarded as absolutely significant, though especially frequent. Motor insufficiency of the stomach is finally mentioned as evidence of the continued presence of partially digested foods, is pretty constantly present in the early stages of the disease and has been called by Einhorn ischochymia, which is a convenient designation. After the increase of ischochymia, with malnutrition, progressive diminution of free HCl and of peptic digestion, with perhaps the addition of pain, the presence of lactic acid and the Oppler-Boas bacillus with atypical mitosis appear to be the most reliable signs at present available. The early diagnosis of gastric carcinoma is one of the most difficult problems to the clinician.

62.—See abstract in The Journal, xxxv, p. 1171.

63.—Ibid.

64.—Ibid.

68. **Some Mistaken Impressions in Regard to Genito-Urinary Troubles.**—The special mistakes noticed by Dowd are: the belief in the frequency of cystitis due to gonorrhea, the frequency of vaginitis, the recognition of albuminuria and casts as always indicating nephritis, while they occur frequently during urethral inflammation with no other disease, and the common notion of the greater seriousness of syphilis as compared with gonorrhea; he also mentions the common belief that twisting or screw-like formation of urination as it emerges is indicative of stricture, which is not the case.

76. **Bacteriology of the Conjunctival Sac.**—From a review of the principal points of his paper, Jameson sums up: 1. Pyogenic organisms are found in the normal conjunctival secretion, but probably in an attenuated form. 2. Under normal conditions these do not propagate. 3. The normal eye is abundantly supplied with means of antagonizing bacterial growth. 4 Diminished resistance from inflammations and operative interference alter the secretion and probably convert it into a better media for germ life. 5. The secretion of the eye is not in itself antiseptic. 6. Strong antiseptics in the conjunctival sac lower the resistance to germ in vision. 7. Much attention should be given to washing out the residual bacteria prior to operation. 8. As much care should be taken concerning antisepsis and cleanliness in the external preparation of both patient and operator as is adopted in general surgery, as, while the danger of suppuration is more remote, its results would be more disastrous.

77. **Choroidal Sarcomas.**—Posey and Shumway report a case in which they call attention to the following points as of interest: 1. The form of growth—intravascular angiosarcoma—developing from the lining endothelial cells of the choroidal vessels. 2. The early appearance of the glaucomatous phenomena. 3. The marked inflammatory changes and hyaline degeneration of the iris and ciliary body. 4. Acute degeneration of the optic nerve. 5. The advanced age of the patient—70 years.

78. **Homatropin.**—From his experience Jackson concludes that homatropin properly used is a reliable and satisfactory cycloplegic, as effective in children as in adults. The preferred method of applying it is in 2.5 or 3 per cent. solution, a small drop on the upper corneal margin every five minutes until five or six drops have been instilled. Care should be taken to avoid irritation. It rarely produces any symptoms of mydriatic intoxication. The bitter taste is the most notable extraocular symptom.

79. **Vernal Conjunctivitis.**—Fox reports a case of this type of conjunctival inflammation which he treated by grattage with success.

80. **Asthenopia.**—The causes of asthenopia are noticed by Schulin, and among the first he mentions auto-intoxication from the bowels, etc., and after that common rheumatic gouty diathesis. Another cause is sexual disorders, and he mentions cases due to gonorrhea and undescended testicles. One of the most frequent causes is a poorly-darkened sleeping room, especially if the sleeping, from any cause, is not profound. The surroundings of the eye in sleep, especially in young children, deserve great attention. He does not put much faith in the poorly-lighted schoolroom as a cause of asthenopia. What trouble comes from this cause is due to twisting of the vision due to narrow, bright windows. He believes that astigmatism and myopia are not as a rule congenital, but originate in early youth, are binocular in origin, being caused by abnormalities of muscles of both eyes, and that these originate mostly in the night time, during sleep.

81. **Obliterating Hyphema.**—Four cases are reported by Weymann, from which he concludes that contusions of the eyeball, resulting in obliterating hyphema, may or may not be complicated with deeper mischief, but the uncomplicated cases are in the minority. They are apt to be followed by acute glaucoma, the chief cause of the suffering. In the absence of sepsis iritis seldom develops. When the contusing force secures non-infected drainage from the anterior chamber, the reaction subsides in six to twelve hours. The stippling of the anterior epithelium and parenchymatous haze are due chiefly to profound shock to the local lymph-system and clouding does not disappear with the irritation of the intraocular pressure; it often lasts a week or longer. Drawing the contused blood is neither practicable nor desirable, for it clots a few minutes after leaving the vessels, and it shuts off the light and serves as a quasi iris splint. Atropia should always be instilled, not only for dilatation, but for its analgesic effect. Glaucomatous tension should be at once relieved by a cataract knife into the anterior chamber parallel to the plane of the iris. This makes a valvular wound which can be opened at will by compression of the posterior wound lip. For the inflammation he orders 6 gr. of calomel, which has an excellent revulsive effect, and compresses, as hot as can be borne, for thirty minutes out of every hour. These are usually not needed after twenty-four to forty-eight hours, at least not so often. No prognostic promises should be made until the clot absorption is complete. The commonest deeper complications are partial or thorough luxations of the lens, consecutive cataract, iridodialysis, synsechiæ, fundus hemorrhage and detachment of the retina.

88. **Pseudo-phosphaturia as the Cause of Persistent Urethritis.**—Schalek reports a case in which a non-specific urethritis, persisting for years in spite of all local treatment, was relieved when the condition of the urine was detected and proper treatment instituted. The nearest resemblance which he finds to the present case was in one reported by Klotz, where, after the cure of gonorrhea, in which repeated examinations failed to find the germs, phosphaturia brought on anew an inflammation of the bladder and urethra. The condition in Schalek's patient is called pseudo-phosphaturia, as no excess of phosphates was present, but it still had the general symptoms of phosphaturia.

89.—See abstract in The Journal of January 12, p. 126.

90.—**Septic Affections of the Kidneys.**—The methods of treating over-alkaline acidity of the urine are first noticed by McArthur, who calls attention to the importance of using benzoic acid, free from an alkaline base, in the treatment of ammoniacal urine. Other remedies useful in acidulating urine and exceeding in value dilute mineral acids are salol and similar derivatives of the benzol group. To check bacterial growth, the most trustworthy urinary antiseptic is urotropin. To render the urine alkaline in reaction, as when the gonococci or bacilli coli invades the kidney, the bicarbonates should not be used. Of the neutral salts the vegetable acids are the best. He classifies the specific affections of the kidney into acute and chronic, and those again into ascending and hematogenous, or descending. The acute ascending infections of the kidney are septic and gonorrheal, and for treatment the better antiseptics mentioned should be used. If these fail, the use of ureteral lavage, and if this also fails there remains nephrostomy as a final resource. The descending infection of the kidney is occasional and may be from pyemic infarcts, but is more frequently due to infection from typhoid and tuberculosis. As a positive causative factor in chronic ascending infection, we have the same micro-organisms as in the acute, but their invasion is generally due to some mechanical obstruction to the free escape of urine, and attention should be given to its removal. With the restoration of free exit, many a case of renal infection has become quiescent. Relief of prostatic hypertrophy or stricture may cause the kidney trouble to disappear. If the renal obstruction has become so great that the removal of the kidney is required, the functional activity of the other kidney and its freedom from disease should be assured, as well as the worthless character of the kidney to be removed. Among the chronic descending, i. e., the hematogenous, varieties we have chiefly the caseous nodules of chronic tuberculous processes.

99. **Urethral Curettage.**—Walker favors the use of a special curette, which is very long and slender, with a rather cupshaped end 2 mm. in diameter and very sharp, in curetting for posterior urethritis; he has had good success in long-standing cases. Preparatory to the operation he irrigates thoroughly with a 1 to 40,000 bichlorid solution, and then a 4 per cent. cocain solution, which is instilled and held five minutes. The endoscope is introduced and the diseased spot localized. The curette is next applied with the complete removal of diseased tissue, including the epithelial layer and submucous tissue, if necessary. After this is done a 10 per cent. solution of nitrate of silver is applied to the spot by means of a cotton pledget. Following the treatment there is usually profuse purulent discharge, for which he has used, twice daily, an irrigation of 1 to 50,000 bichlorid solution.

106.—This paper was considered editorially in last week's Journal.

111. **Stereoagnosis.**—Two cases are reported by Burr, whose conclusions are as follows: The ability to recognize objects by handling them depends upon the integrity of the afferent nerves, the cortical sensory area, and the cortical perceptive area. Diseases of either of these will affect the function. We may dismiss from consideration the inability to recognize objects because of disease of the sensory nerves or tracts in the cord, medulla and pons. Such inability is due to anesthesias of one or more types. There is a distinct area in which the sensations of handling objects are grouped, which form tactile memory impressions. This, the tactile perceptive area, is in the parietal lobe. This is not the same thing as the sensory area, though it may be located within the boundaries of the latter. It would probably be well to limit the term stereoagnosis to cases where the inability to recognize objects by contact is due to some failure of sensation caused by brain disease either in the cortical sensory area itself or in the fibers going to it. Tactile amnesia includes cases in which, on account of disease in the tactile perceptive area, the tactile memory images are destroyed. It is not infrequently associated with mind blindness, and it is probable that in recognizing objects by handling we recall, from memory, a more or less faint recollection of its visual appearance. Auditory memories are less frequently recalled because less frequently needed. What form of sensation is the most necessary for the recognition of any given object depends on its qualities. Tactile anesthesia, if sensibility to stronger pressure is preserved, causes little or no difficulty. The space sense, the localizing sense, and the sense of position are probably the most important, for by them we learn the form of objects. When, in the cerebral palsies of children, there is an inability to recognize objects in the paralyzed hand, it is often due, as Oppenheim states, to the fact that tactile memory images were never acquired. Granting that the tactile perceptive area is not the same as the cortical sensory area, such cases as the second reported can be explained upon the hypothesis of a lesion cutting off the fibers joining the two areas.

117. Foreign Bodies in the Peritoneum.—Beck reports cases in which non-absorptive silk ligature was sloughed through into the bowel or bladder or other hollow organ of the body, and he concludes that silk ligatures and sutures are not as harmless as usually regarded, and that more absorptive material should be preferred. If non-absorptive silk material is used, the thread should be small in size, and interrupted suture should be preferred to the continuous one, as the latter takes a longer time to slough off. Symptoms arising from a buried suture must always be borne in mind, and if sloughing is suspected a way should be opened for the thread so that it may not take a dangerous route. Some of the cases show that even the absorptive sutures are liable to this accident.

120. Pryor's Vaginal Hysterectomy.—Crouse reviews the indications for the operation and describes the technique. Pryor's operation, he says, has been evolved from Doyen's anterior hemisection, Muller-Quenu's total hemisection, Segond-Pean's preliminary liberation of the uterus, thus guarding the ureter, Czerny's twisting of the pedicle to 180 degrees, with the placing of the forceps from above downward. It embodies careful covering of the stump, thus securing the extraperitoneal retention of the pedicles; it is the Pean morcellating method in fibroids and large uteri. But after all, it is Pryor's, and an American operation by an American operator. The *mortality in Pryor's hands has been nil.* Its advantages over the other vaginal procedures are: 1. No stitches nor ligatures, and increased speed and ease. 2. The use of clamps which can be applied to dense, short ligaments where ligatures are not applicable, as in cases in which the parametria are very much thickened. Clamps can be placed closer to the outer part of the broad ligament if this is at all infiltrated, than it is possible to place ligatures. 3. It has all of their good and none of their bad features.

140. Protonuclein.—Canan has attempted to classify his cases of tuberculosis, keeping a record of all that were treated with protonuclein. The classification adopted was that of circumscribed apyrexia, circumscribed febrile tuberculosis, tubercular laryngitis, tubercular broncho-pulmonitis, and tubercular broncho-pulmonitis with cavities. In each case the bacilli were found. The patients were from all walks of life, between the ages of 60 and 70 years, and of both sexes. Of the apyrexia cases, 39 were treated, and 5 were cured, 18 improved, 9 remained about the same, and 7 grew worse and died. Of the tubercular laryngitis cases, 27 were treated, 3 cured, 12 improved, 6 stationary, and 6 died. Of the circumscribed febrile, 32 were treated, 8 cured, 16 improved, 5 stationary, and 3 died. Twenty-one cases of tubercular broncho-pneumonia with cavities were treated, 4 cured, 10 improved, 3 remained stationary, and 4 died. He claims that this treatment, while not a specific for tuberculosis, can do very much good and save many lives. There is no danger of its dealing the last blow to an already tottering structure, as is so often the case with tuberculin. While the treatment was in progress, he noticed: 1. That pyogenic associations are not acted upon by protonuclein. 2. That negative results are manifested when administered to patients with disease so far advanced that the cells are unable to respond to the stimulus of the drug. 3. That when improvement once begins under this treatment it generally continues. He reports one case in which cavitation had occurred, and improvement was very striking.

Combined Gynecologic Operations.—Owing to a combination of errors in typewriting and proofreading, the notice of Sutton's article, "Combined Gynecologic Operations" (page 599, The Journal, March 2), contained two absurd errors: For "tracheotomy," read trachelorrhaphy, and for "craniotomy," laparotomy.

FOREIGN.

British Medical Journal, March 2.

Some Points Relating to Varicocele. William H. Bennett.—The writer notices the hypochondriasis and mental symptoms generally as occurring with varicocele, and describes its varieties. About 7 per cent. of men will be found to suffer from this condition, and 80 per cent. of that percentage will be affected on the left side only, about 15 per cent. on both sides, while occasionally the right side only is affected. The percentage of cases in which it gives trouble, excepting from mental causes, is small, and quack literature is responsible for many of these latter. He recognizes two forms, in one of which the condition appears like a bag of worms, and this is the commonest type. Excepting in cases of injury, it is perfectly harmless. There is another kind, however, where the veins are very small and massed together, and very numerous around the testicle, the upper part of the cord being normal. This kind may produce trouble in the way of atrophy of the testicle, influencing of nutrition, the result of abnormal growth of the veins. For the relief of the condition radical operation is advisable, and the method that he follows is a complete division of the whole of the spermatic cord, with the exception of the vas deferens. He has performed this operation more than two hundred times. It is the best method for preventing recurrence of the condition. He makes an incision of one-half to three-quarters of an inch, severs the cord on a level with the upper border of the root of the penis, i. e., over the external abdominal ring, and pulls out the whole of the spermatic cord excepting the vas deferens, by means of an aneurysm needle or hook, which is passed between the vas deferens and the rest of the cord. The veins here are not dilated—an essential point—and are only seen through the translucent fascia; inside the fascia, with the veins, is generally the spermatic artery. He pulls the loop out through the wound, the next step being to tie a stout ligature of carbolized catgut around it in two places. A considerable piece is excised and the two stumps are united by a kangaroo or catgut suture, considerable structure having been removed. He intentionally includes a segment of the spermatic artery in the removed section, and claims that the vessels which accompany the vas deferens, together with a few small vessels derived from the subvaginal cellular tissue, are sufficient to nourish the testicle. When he first began to perform the operation, he feared wasting of the organ, but this has not followed. The spermatic artery is a large vessel for the work it performs, and is enlarged still more in varicocele. If it is left there would be engorgement of the organ for the time being, which might lead to fatty degeneration. On the other hand, if the main artery is obliterated, the blood carried by the artery of the vas deferens and other small arteries is sufficient to nourish the testicle without producing engorgement.

Influence of the Dwelling upon Health. John F. J. Sykes.—The question of the influence of the dwelling upon health is discussed by Sykes, who finds the increased density to the square space causes an increased general and special mortality in unsanitary areas. The general mortality is increased at all ages, but particularly under one year. The special mortality shows the greatest increase in infectious diseases, the next greatest in tuberculous diseases, the next in respiratory disorders. If all infectious cases be promptly removed to hospitals, and disinfection and cleanliness enforced, the increase will take place in the reverse order, the respiratory diseases first, the tuberculous next, and the infectious third. In a series of industries arranged in order of the purity of the air considered apart from dusty occupations, the order would be that of the mortality of diseases of the respiratory organs together with phthisis. The greater proportion of the diminution in phthisis mortality among females, the more indoor of the two sexes, is significant of improvement of dwellings, and it is more notable since the greater diminution has taken place between the ages of 15 and 45 years, the child-bearing period, when women are most sedentary. The size of the dwelling has an influence on the mortality. The mortality in dwellings of one room may be nearly double that of larger dwellings, and this is especially noticeable in tuberculous disease. The most important factor in the spread of pulmonary tuberculosis is the predisposition to this condition, acquired as well as innate. Moreover, the acquired or innate predisposition can be controlled to a large extent by the hygienic conditions. The phthisis death-rate shows a close relationship to the density of persons in cubic space, and the disease seems to stand in the same relationship to respiratory pollution as typhoid does to filth pollution. The effects of back-to-back houses, as constructed in the north of England, are also stated, and in such the death-rates from all causes are greatly increased. The death-rate in dwellings over stables is also specially noticed, and the conclusions are that occupants of these have a high birth-rate and high mortality under 1 year and at all ages; high death-rates from pulmonary disease, both in infants and adults, and high in zymotic diseases, especially diarrhea and diphtheria. Much of this is attributable to drafty conditions of stables affecting the dwellings over them.

The Lancet, March 2.

Influence of Ozone on the Vitality of Some Pathogenic and Other Bacteria. ARTHUR RANSOME AND ALEXANDER G. R. FOULERTON.—These authors have experimented on the action of ozone: 1. On the vitality of certain pathogenic and saprophytic bacteria. 2. On the virulence of bacilli of tuberculosis. They detail their experiments, referring to former workers, especially Downs, Blunt and Ohlmüller, and conclude that ozone in the dried state, and in such strength as used, has no appreciable action on the vitality of the various bacilli experimented with, their results being in accordance with those of Sonntag and Ohlmüller, nor did prolonged exposure to the action of ozone diminish in any way the pathogenic virulence of the bacilli of tuberculosis in the sputum. Single experiments appear to show that it has little if any effect on the pathogenic virulence of the bacillus mallei and the bacillus anthracis. On the other hand, one experiment appears to confirm the conclusion arrived at by Ohlmüller, as to the bactericidal properties of ozone when passed through a fluid medium containing bacilli in suspension. The non-activity of ozone as a disinfectant in the dried state, compared with its action in the presence of water, suggests a superficial resemblance to other gases, such as chlorin and sulphur dioxid. The authors, therefore, consider that in the dry state and under natural conditions ozone has no effect on the bacteria, and any purifying action which it may have in the economy of Nature is due to chemical oxidation of putrescible organic material, and it does not hinder the action of bacteria which are working toward the same thing in their own way.

Quantitative Estimation of Bactericidal Power of Blood. A. E. WRIGHT.—In a previous communication dealing with the quantitative diminution of the bactericidal power of the blood, Wright described the technique of the method, by using a series of graduated dilutions of serum mixed in capillary culture-tubes, with equal volumes of liquefied gelatin and cultures containing in suspension the proportionate number of species of micro-organisms to be tested. The questions considered in the present communication are whether, where no colonies are developed in these cultures, it may be inferred that the bactericidal effect has been complete and the question of the influence exerted on the results of the quantitative estimation of the bactericidal power by the greater or smaller number of bacilli in the volume of culture brought in contact with the serum. The experiments undertaken to answer these questions are detailed and methods described. The conclusions the author reaches is that what was measured by the method described in his former article is rather the total antibacterial power of the blood than the bactericidal power proper. Where it is desired separately to estimate the bactericidal power, this can be done by making a series of graduated dilutions of bacterial cultures and growths, and by mixing, in the manner described in the present communication, one volume of each of these with one volume of undiluted, or, if necessary, diluted serum. When this last method is employed, and the bacteria in the cultures have been enumerated in the manner indicated, a convenient arithmetical expression for the bactericidal power is obtained by the specific number of micro-organisms, which 1 c. mm. of serum is capable of killing. Where—as in the case of the staphylococcus and apparently also in the case of the streptococcus and bacillus of plague—we have to deal with bacteria which are not killed off, or are killed off only in small numbers, by the normal human blood, or, again, where we are dealing with conditions (such as those frequently met with in convalescents from typhoid) when the blood has lost much of its normal bactericidal power, the gelatin method, measuring as it does the combined inhibitory and bactericidal power, may appropriately come into application.

Method of Distinguishing Bacillus Coli Communis from Bacillus Typhosus by the Use of Neutral Red. WILLIAM HUNTER.—The author finds, from his studies of the subject, that: 1. The bacillus coli communis possesses to a marked degree the power of reducing neutral red, producing a superb canary-yellow, fluorescent color of the medium. 2. The so-called bacillus enteritidis of Gaertner also produces this reaction, and is probably only a variety of bacillus coli communis. 3. The bacillus typhosus never possesses this power of reduction. 4. The common pathogenic micro-organisms do not give this reaction. 5. By means of neutral red it is possible, within from twelve to twenty-four hours, to diagnose the presence of bacillus coli communis with absolute accuracy. Finally, as far as his experience goes, it is possible to diagnose, by means of neutral red, the true coli group from the typhoid group of micro-organisms.

Archives Gen. de Med. (Paris), February.

Subacute Adenitis of the Groin. MANON AND GANDY.—An adenitis in the inguinal region, remarkable for the multiplicity of the foci and the protracted course, has been described by various authors. The pus shows no micro-organisms on direct examination and no cultures can be derived from it, consequently the affection has been assumed to be a simple adenitis with intraganglionary purulent foci. The authors of this communication state, however, that it is exclusively and probably invariably tubercular and promptly heals after extirpation, curetting and packing with iodoform gauze. Animals inoculated with the pus exhibited local and general manifestations of an attenuated tuberculosis in every case. Four out of a number of clinical cases are described in detail.

Two Cases of Primary Carcinoma of Biliary Passages. LECÈNE AND PAGNIEZ.—Two new cases of primary juxtahepatic carcinoma of the biliary passages are described, and the ten cases already in the literature. They were all circumscribed but inoperable, obstructing the large biliary passages at their emergence from the liver. The symptoms were those of chronic icterus from retention.

Bulletin Medical (Paris), February 13.

Influence of Spinal Cocainization in Hastening Delivery. DOLÉRIS.—Fifty obstetric cases in which spinal cocainization was employed have convinced Doléris that cocain has a directly aggressive action in stimulating the uterine muscle to contraction. He affirms that we have in spinal cocainization a new means of inducing premature delivery, on account of this oxytocic action on the motor nerves of the uterus. It is, therefore, contra-indicated for operations during pregnancy on account of the danger of inducing abortion. He found it invaluable in two cases of uterine inertia, and suggests that it may be useful in eclampsia, in which rapid delivery is often desirable.

Gaz. Hebd. de M. et Ch. (Paris), February 17.

Mercurialized Artificial Serum in Syphilis. BAILEY.—Experiences with 70 syphilitics treated with mercurialized serum are described. The action was as energetic as that of calomel, and it was tolerated by the patients as well as grey oil, while the administration is simpler, easier and much less painful for the patient. Clinical recovery followed an average of 3½ injections. The formula is: mercuric bichlorid, 5 gm.; sodium chlorid, 2 gm.; boiling distilled water, 200 gm., and, when cooled, carbolic acid, 2 gm. Only thirteen of the 250 injections were painful. The amount injected averaged 20 c.c. during the week. Slight stomatitis was noticed in four cases.

Journ. de Physiologie (Paris), January.

Pathogenesis of Acute Edema of the Lung. J. TEISSIER.—Nervous influences favor the production of acute edema of the lung in animals by dilating the capillaries of the parenchyma. This influence is more pronounced in cases of preceding intoxication entailing a tendency to serous suffusion. The edema may occur without increased pressure in the left ventricle, but never without a simultaneous increase in the pulmonary pressure.

Protecting Power of the Skin. J. Lefèvre.—The experiments reported seem to demonstrate that the protection afforded by the skin is the same as from a covering of wood or cork about 2 mm. thick. It protects against cold 750 times less effectively than a layer of still air 2 mm. thick, but it protects 2280 times better than a silver envelope and 1750 times better than copper. The conductibility is less by one-half at 5 than at 30 C.

Thyroid Grafts. H. Cristiani.—The thyroid gland transplanted whole or in portions in the peritoneum, or under the skin of an animal of the same species, lived and developed histologically, apparently the same as if it had remained in its original environment.

L' Obstetrique (Paris), January.

Vomiting of Pregnancy with Ovarian Cyst. L. Lapeyre.—Uncontrollable vomiting does not occur in pregnancy complicated with an ovarian cyst, with any more proportionate frequency than in simple pregnancy. When it occurs it is due to the pregnancy and not to disturbance from the cyst. A case is described in which the cyst was removed in the hope of arresting the vomiting, but no relief was experienced until labor was induced. In urgent cases the patient can be delivered at once and the ablation of the cyst postponed. Certain ovarian cysts, Lapeyre adds, are better removed through the vagina, especially during the course of a pregnancy.

Revue Mens. Mal. Enf. (Paris), January and February.

Abscess of Liver from Contusion in Children. C. Oddo.—Four of the nine cases of traumatic abscess of the liver in children, collected by Oddo, terminated fatally. The symptoms sometimes appear at once after the contusion, or a period of latency may intervene. If the traumatism directly affected the liver, the abscess is primary, but occasionally it occurs consecutive to injury of some other region of the abdomen. Fever may be remittent or continuous. The cachexia is rapid and pronounced. The abscess tends to perforate through the skin or into the respiratory apparatus, possibly directly into the bronchi. It may entail a purulent pleurisy and produce a subdiaphragmatic pyo-pneumothorax. Surgical or spontaneous evacuation is followed by rapid improvement.

Alterations in the Bones in Rhachitis. L. Spillmann.—Histologic study of the bones of forty-four children of various ages indicates that rhachitis passes through three stages in its course; latent, deformity and convalescent. In the second stage vascular neoformation is the chief lesion. The proliferation of cartilage cells and disturbances in ossification are secondary. The rhachitic process is essentially an osteitis, both juxta-epiphysial and subperiosteal.

February.

Purulent Rhinitis in Scarlet Fever. C. Laprée.—A purulent coryza entailed complications which proved fatal in eighteen out of thirty-nine cases in Laprée's experience. The statistics of others also indicate that purulent coryza is the most frequent cause of death in scarlet fever. It may be preceded by a simple coryza, or may appear suddenly without warning, the second or third day, or as late as the tenth day. It usually coincides with severe sore throat and general symptoms. It aggravates the disease, keeps the temperature above 38.5 C. for several days and debilitates the patient. Treatment should be prompt and energetic, destroying the germ in the local infection before it infects the entire organism. The nasal fossæ and throat should be copiously rinsed with an antiseptic, preferably peroxid of hydrogen mixed with an equal volume of a 4 per 1000 solution of sodium bicarbonate. This irrigation should be repeated three or four times a day and at least twice at night. Afterward the nostrils are plugged with cotton impregnated with a mentholized or resorcin salve. This treatment may arrest the rhinitis in thirty-six hours, but it usually continues for three days. If the discharge persists after the fifth or sixth day, an irrigation morning and night is usually sufficient. Laprée recommends irrigation through a Nélaton sound in which three holes have been cut about the center with the scissors. The sound is inserted through the nose and passes out at the mouth.

Revue Scientifique (Paris), February 23.

Pain from the Surgical Point of View. J. Lucas-Championnière.—Pain causes reflexes of all kinds and may survive the cause that produced it. Pain begets pain. The longer it lasts the more obstinate it becomes. In examining a patient these facts should be borne in mind and every effort made to refrain from causing pain, as it is liable to induce reflex action which will mask the symptoms that are being investigated. "By mobilization and massage, pain is abolished in 80 per cent. of all cases of fractures managed according to this method."

Berliner Klin. Wochenschrift, February 4.

Oxygen in Exhaustion of the Neurons. Max Verworn.—In a study of fatigue and exhaustion Verworn shows that the neurons become fatigued and exhausted just like the muscles, and, like them, throw off waste matters, the products of their metabolism, which, if not removed, paralyze their further action. He relates experiments with frogs under the influence of strychnin. When so exhausted that no further convulsions were possible, he was able to restore the original energy to the convulsions by the establishment of an artificial circulation with salt solution mixed with pure oxygen. The former alone had no effect. He therefore concludes that exhaustion is due to the using up of the oxygen in the neurons and cells. He believes that conditions of fatigue and exhaustion are the chief factors in neurasthenia, or they may be the actual cause of the entire symptom-picture. His synthetic production of the conditions that create fatigue generated a symptom-complex closely resembling neurasthenia, and in all his experiments it was cured by the direct application of the oxygen in salt solution in artificial circulation.

Centralbl. f. Chir. (Leipsic), March 2.

Improved Spinal Cocainization. K. Schwarz.—Instead of cocain, Schwarz uses tropacocain, and reports that in sixteen serious operations performed with the subarachnoid injection of tropacocain, the analgesia was perfect and there was not a trace of the inconveniences observed after the use of cocain for the purpose, no pallor, vomiting, headache, vertigo nor rise in temperature. The general health was not affected in the slightest in any way, either during or after the operation. Analgesia to the knees was obtained with 3 cg. With 4 cg. he curetted an osteomyelitic hip-joint and removed sequestra in a very sensitive patient, without causing the least pain. The analgesia was complete for radical hernia and hemorrhoid operations, with 5 cg. This amount also proved sufficient in a uroseptic patient, 66 years of age, much debilitated, with complete retention of urine for two days in consequence of a traumatic stricture. The operation lasted two hours and the analgesia was complete to the end.

Restoration of Co-ordinated Movements After Nerve Crossing. R. Kennedy.—Experiments on five dogs showed that the nerves supplying the flexor muscles in a foreleg could be severed and sutured to those supplying the extensors, with the result that in spite of this changed innervation, the animal gradually recovered the normal use of its limb and was able to make voluntary co-ordinated movements with it as before. The interval before function was re-established was the same as in case of simple section and immediate suture of the nerve. The nerve-centers which formerly innervated an antagonistic group of muscles now serve for the other group and the change extends even to the nerve centers, which change their task while retaining their excitability: the cortical centers duly impart impulses to the muscles that result in co-ordinated movements in their new peripheral domain. Applying these facts to human pathology, a woman was cured of facial spasms by uniting the peripheral stump of the severed facial nerve with the trunk of the spinal accessory, at the point where the latter emerges beneath the posterior belly of the digastric muscle. The interposing digastric prevented reunion of the severed ends of the facial nerve. Paralysis of the right side was the immediate result, but this gradually subsided. By the forty-ninth day there was reaction to faradic stimulation and partial closing of the lids. Fifteen months after the operation the face feels normal; there has been no recurrene of the spasm; the conjunctiva, muscles and lacrimal secretion are normal, and the movements of cheek and mouth muscles are satisfactory although not perfectly co-ordinated. There is no atrophy of the face; the tonicity of the muscles and their outlines are normal. There is muscular insufficiency in whistling, blowing and raising the eyebrows, but the labials are distinctly pronounced and the buccinator prevents accumulation of food between the jaw and cheek. When the arm is suddenly raised the face contracts on that side for a moment. The impulse for the trapezius is dispatched first to the face. The article concludes with the suggestion that section of a nerve supplying a paralyzed muscle, and union of this nerve with a neighboring nerve, even of an antagonistic group, may restore function to the paralyzed muscle.

Deu. Archiv f. Klin. Med. (Leipsic), December.

Experimental Study of Gout. M. Freudweiler.—Subcutaneous injection of sodium biurate produced lesions in animals, in Freudweiler's previous experiments, which corresponded anatomically in every particular to typical arthritic lesions in gout. The necrosis of the tissues was not a foreign-body necrosis but a secondary process, the result of the specific, toxic action of the urate. Under the administration of large amounts of acids or alkalies, the gout nodules rapidly disappear, and phagocytic processes are probably the chief factors in this retrogression of the nodules. His latest research tends to establish that in gout there is a permanent saturation of the organic juices with uric acid, entailing a constant tendency to local inflammation. If an inflammatory process culminates at a time when the organic juices happen to be supersaturated with uric acid—owing to improper diet or other causes—then the uric acid is deposited in crystals in the exudate of the inflammatory process. This is the origin of the typical gouty nodule with consecutive necrosis of the tissues involved. The precipitation of the uric acid relieves the organism from the superfluity, and no further trouble is experienced until again an acute local inflammatory process coincides with a maximal saturation with uric acid. The latter may also be deposited at points free from inflammation, where conditions are unfavorable for its retention in solution. The essence of gout, however, as a typical constitutional disease, is not the accumulation of uric acid in the fluids, but is to be sought at the points where uric acid is elaborated.

Deutsche Med. Wochenschrift, February 28.

Transmission of Tuberculosis by the Semen. F. F. Friedmann.—The experimental research described has been aided by funds from the Bose endowment for scientific research. Friedmann has succeeded in transmitting tuberculous infection directly with the semen, and when the animals were killed six days later, the tubercle bacilli were found ensconced in the embryo, with none loose in the uterus or vagina. One or two drops of a very weak suspension of tubercle bacilli were injected into the vagina of female rabbits directly after coitus, following soon after a litter had been thrown. More than 500 longitudinal sections were made of the embryo and uterus of the animal killed the sixth day, before the embryo had become attached to the uterine wall in any way. The bacilli were found inside the cell of the embryo in every instance, and in one case a nest of them was discovered. The remainder of the bacilli had evidently been eliminated by the vaginal secretions, only two were found outside of the embryo and these were close to it. The question whether the non-motile bacteria were carried by the spermatozoa into the ovum is still undecided, but the experiments demonstrate beyond all doubt the possibility of the transmission of bacteria with the semen directly into the embryo, without the participation of the maternal organism in any way.

Suppuration in Typhoid Fever. A. Prochaska.—During the last three years this author has seen twenty-two cases of abscess formation in typhoid fever, mostly deep lesions, with multiple foci in several cases. One patient died. It is possible that pyogenic germs present in the body may acquire unwonted virulence under the influence of the typhoid infection. As such micro-organisms are swept away in the circulation, the abscesses may develop at points remote from their primary localization.

Spontaneous Gangrene in Young Men. Wulff.—Two cases are described in detail, but Wulff has observed five in all. Israel has also seen a number in the last few years. The patients were all Jews from Russian Poland, between 20 and 35 years of age, free from hereditary or syphilitic predisposition. All smoked cigarettes to excess, thirty or more a day for years. The gangrene first appeared in the toes in all but one case, and was preceded by years of rheumatic pains in the leg with chilliness, tingling and sluggish circulation when the leg was dependent. Wulff is inclined to attribute the etiology to abnormal vasomotor constriction, inducing secondarily the endarteritis and thrombosis which are the essential factors in senile gangrene.

Deu. Ztft. f. Ch. (Leipsic), January.

Rydygier's Experience with Operations on Stomach.—Since 1880 Rydygier has performed 100 operations on the stomach. The fatalities have been 17 in 25 cases of pylorectomy for cancer, and 4 in 7 non-cancerous affections; 16 in 38 gastro-enterostomies for cancerous and 5 in 26 for non-cancerous affections; 1 in 3 gastrostomies for cancer and 1 successful case of non-cancerous dilatation of the pylorus. The majority of the deaths were due to weakness and shock; 11 to pneumonia; 7 to peritonitis; 2 to hemorrhage and 7 to unknown causes.

Peptic Ulcer After Gastro-enterostomy. A. Neumann.—Seven cases have been recorded during the past eighteen months, in which a peptic ulcer has developed in the jejunum consecutive to gastro-enterostomy. Neumann has recently observed another case. The patient had suffered from chronic gastritis, dilatation and hyperchlorhydria, with stenosis of the pylorus. Gastro-enterostomy was done, and later an entero-anastomosis. He returned after a year with symptoms of a gastric ulcer adherent to the anterior wall of the abdomen. The tumor was excised. Six months later the cicatrix became perforated. The defect was closed with a pedunculated flap, the skin side toward the stomach. In a few days this flap was digested and the gap opened directly into the stomach and into the lumen of the intestine on each side. As the stomach and pylorus were now of normal shape and size—the stenosis having probably been spasmodic—the gastro-enterostomy was undone, the stomach closed, a portion of the jejunum resected and the abdominal defect closed with a piece of omentum inside and a skin flap outside. Neumann points out that the jejunum is not made to resist the action of acids and that, consequently, when brought directly in contact with them, as in a gastroenterostomy, favorable conditions for a peptic ulcer are produced. If the stenosis of the pylorus is not organic, jejunostomy should be preferred to gastro-enterostomy. Four of the seven cases mentioned above succumbed to the results of the perforation into the abdominal cavity.

Monatss. f. Prakt. Derm. (Hamburg), November.

Alcohol Pencils in Dermatology. P. G. Unna.—These pencils are recommended by Unna as a very convenient method of applying alcohol in skin affections. He is convinced that we have in alcohol a harmless, mild and actively efficient disinfectant when used intermittently, not continuously. To prevent too rapid evaporation he applies it in the form of a thin, invisible varnish. This is accomplished by casting it in moulds with 5 or 6 per cent. of sodium stearate, in the shape of a pencil, and rubbing this pencil over the surface to be treated. The pencil is wrapped in tin-foil when not in use.

Muenchener Med. Wochenschrift, February 26.

Hereditary Transmission of Tuberculosis. J. Goldschmidt.—The English colony in Madeira was composed almost exclusively of persons with tuberculosis seeking a temperate climate. It has numbered about 600 souls, and yet, during the entire 19th century, only one of the descendants died of pulmonary tuberculosis, possibly acquired in a residence of several years abroad. The community now consists of about

150 persons. In contrast to this experience of the non-transmissibility of tuberculosis from the progenitors, Goldschmidt cites twenty-eight families of various nationalities in which both parents were free from the slightest trace of tuberculosis. In 21 of the families, all the children died of tuberculosis between 15 and 35 years of age; in 5 others most of the children died, and in 2 others two children in each were affected with a tubercular affection of the bones. He points out that in 21 of these families the fathers were syphilitic. There were only 8 abortions in the record of all the families. He suggests that the paternal syphilis might have induced a predisposition to tuberculosis. He also is inclined to believe that the parental tuberculosis in the Madeira colony conferred a sort of immunity on the children.

Jolles' Improved Ferrometer.—Comparison of the readings of the hemometer and of the ferrometer affords valuable information in many cases, not to be derived from either alone. The hemometer shows higher and lower amounts of hemoglobin in icterus, corresponding to the progress and subsidence of the affection. The more intense the icterus the greater the difference between the readings of the hemometer and of the ferrometer. In hemorrhagic diseases the hemometer indicates a high figure, while the blood-iron is diminished both comparatively and absolutely. Two periods in childhood seem to be distinguished by a special abundance of iron in the blood, the period of transition from nursing to a mixed diet and puberty. It is important in treating various affections to determine the amount of blood-iron as well as the hemoglobin and the number of red corpuscles. For these and other reasons Jolles considers his improved ferrometer a valuable contribution to scientific methods of investigation. He has simplified and adapted it to Fleischl's hemometer, so that the latter instrument with a slight addition, can be made to serve two purposes. The blood is evaporated, incinerated and treated with potassium sulphate as by the original method. One of the cylinders is placed in front of the glass wedge of the hemometer and the other over it. The wedge is then moved along until the fluid in both tubes is of the same color. The illumination must be from a candle or lamp, not an electric light. It should shine on the reflector only, and he recommends a covered box for the lamp, open at the back, with one small square aperture opposite the reflector. This improved ferrometer is so simple and so easily managed that he trusts it will be found of general clinical utility. He has already come to the conclusion that the amount of blood-iron in normal conditions averages higher than the figures he has previously announced—.0413 to .0559 in 100 c.c. of blood.

Therapeutische Mon. (Berlin), January and February.

Treatment of Peritonitis with Alcohol Compresses. MEYER.—The advantages of local application of alcohol have been proclaimed by Buchner and others from time to time. By the influence of the alcohol on the nerves of the affected region, strong hyperemia is induced and leucocytes charged with bactericidal enzymes are attracted to the spot and, by their proteolytic action, may destroy the elements of the cutis and lead to the perforation of the purulent collection. Meyer describes a severe case of tubercular peritonitis in which circumstances rendered surgical intervention impracticable. He applied compresses of alcohol, and in two weeks fluctuation was evident and a week later pus perforated through the umbilicus. The child recovered and has gained remarkably in weight.

Salol in Diabetes.. TESCHEMAYER.—In accordance with Ebstein's advice, 1 gm. of salol was administered four times a day, to eight diabetics. In three severe cases no effect was perceptible, but in the others the sugar vanished completely from the urine during the treatment and for the several days afterward before the patients were lost to view. While the urine was under the influence of the salol, the plane of polarization was deflected to the left.

February.

Igazol in Treatment of Tuberculosis. HOFFNER AND BEERWALD.—The communication of the first writer reports negative results in ten cases from the action of Cervello's method of treating pulmonary tuberculosis with iodoform-formaldehyde, but Beerwald, on the other hand, asserts, from an experience with twelve patients, that it is the best of all methods known to date for treating bronchitis with secretion, whether tubercular or not. Ten of his patients were very much improved by the treatment.

[According to Ehrenfeld, in the *Wien. Med. Woch.* (January 26 and February 2), thirty-four patients with pulmonary tuberculosis—all severe cases—were treated according to Cervello's method inhalations of iodoform-formaldehyde-igazol. Improvement was evident in 53 per cent., including 4 clinical recoveries, 8 marked improvements, and 6 patients somewhat benefited; 8 patients died.—ED.]

Therapie Der Gegenwart (Berlin), February.

Quinin in Typhoid Fever. C. BINZ.—To supplement Erb's communication on this subject, abstracted in THE JOURNAL of February 9, p. 412, Binz recalls his experience during the Franco-German War, when he treated some of his soldier-patients with quinin and others without. Of the latter, 11 out of 46 died, a mortality of 23.81 per cent., while only 6 of the 97 to whom he administered 1 gm. of quinin every evening died. He always prefers the hydrochlorate to the sulphate, as it is more easily dissolved and absorbed in the stomach.

The "Klopfen" Method of Treatment of Pulmonary Tuberculosis. J. FRIEDLAENDER.—An unscientific work has recently been published proclaiming the advantages to be derived from slapping the thorax all over with a silver paper-cutter. Friedlaender has been making a scientific study of the method as practised empirically for years by the author, Erni, and finds that it is actually a powerful means of mechanically stimulating, shaking up the stagnant conditions, and thus promoting spontaneous healing of tubercular processes. The thorax is bared and greased. The silver knife is 1.5 cm. wide, and weighs 100 gm. It is held with the wrist loose and allowed to fall at rhythmic intervals on the surface of the thorax, going systematically over the entire expanse, front and rear, avoiding the sensitive points, the mamma, sternum, clavicles and spine. The sitting lasts ten to fifteen minutes with a respite of two or three, repeated every second day for ten to fifteen times and resumed after a pause of a few weeks. The skin smarts during the slapping, but it is followed by an agreeable glow. The respiratory symptoms are improved at once, expectoration promoted and suggestion shares in the general benefit that follows. A local reaction on the part of the lung tissues is evident in many cases, manifested by symptoms that suggest "a fresh cold," a foreign-body irritation from the increased throwing-off of the waste products. When this passes away, in a few days, it leaves the patient unmistakably improved in every respect. He observed that in 39 out 46 patients with hemoptysis the hemorrhages did not recur afterward, but in the 7 others the tendency to hemorrhage was not affected. In patients with hemoptysis, Friedlaender would avoid the vicinity of the lesion and, in fact, he regards the procedure as a general rather than a local measure.

Applications of Cold as a Cure for Pruritus. G. KLEMPERER.—The genital pruritus of diabetes, icterus, neurasthenia or senility is frequently arrested by applying an ice-bag to the abdomen or chest, or by spraying with ethyl chlorid. The local anesthesia of the spot thus treated induces reflex inhibition which may check or relieve the general pruritus for several hours.

Wiener Med. Blaetter January 24.

New Method of Reducing Obesity. W. MLADEJOVSKY.—Very small doses of thyroid extract were combined with quinin, theobromin and a course of Marienbad water. The results were surprisingly satisfactory. The patients lost one to three kilos. a week. Many of them had tried numerous other methods of treatment in vain. The thyroid tablets were taken on an empty stomach, never more than two tablets of 30 cg. a day, followed by the water. No inconveniences were observed in any case, and all the patients have continued in good health.

Lo Sperimentale (Florence), LIV, 5.

Vitality of Isolated Skin Flaps. P. PEZZOLINO.—Krause-flaps from dogs, kept in salt solution from twenty-four hours to six days, retained their vitality and healed in place on aseptic granulating surfaces. Even after ten days some of the cells were still viable and mitosis promptly commenced. Flaps kept at the freezing-point retained their vitality twenty-four hours longer than those kept at room temperature. Dry flaps were much less satisfactory. The maximum of preservation of vitality was 264 hours.

Revista de Medicina Tropical (Havana), I, 6.

Inguinal Adenopathy. R. MENOCAL.—Attention is called to the frequency of ganglionary adenopathy in the tropics, aside from that of venereal or established tubercular origin. They have no significance for the diagnosis of deep-seated malignant disease. Menocal has operated on 59 patients. In 30 the adenopathy was preceded by attacks of lymphangitis, ecthyma of the ankles or interdigital eczema; in ten, by traumatism of the feet or ankles. The hypertrophy was considerable, and in a third of the cases was accompanied by acute or chronic adenophlegmons. Unless the hypertrophied ganglia are excised, ulceration or an interminable fistula is liable to persist.

Negative Diazo-Reaction in Yellow Fever. A. D. ALBERTINI.—The diazo-reaction does not occur in typical cases of yellow fever without complications. It was observed in only ten out of 142 cases of the disease, and they were all complicated by pneumonia, typhoid or some other affection.

Queries and Minor Notes.

"IF I SHOULD DIE TO-NIGHT."

CEDAR FALLS, IOWA, March 2, 1901.

To the Editor:—Will you please tell me where I can get the article referring to a doctor and his creditor, which runs something like the following: "If I should die to-night and you should come to pay that ten dollars that you owe," etc I think it is a parody on the poem, "If I Should Die To-night" F. N. M.

ANS.—The reference is probably to Ben King's poem, "If I Should Die To-night":

> "If you should come with deepest grief and woe,
> And say here's that ten dollars that I owe,
> I might rise up in my great white cravat
> And say, What's that?"

We believe that this poem itself was a parody on some former one of the same title. It has been parodied also so as to refer to doctor's bills, but we can not put our hand on the reference. Possibly some of our readers can assist us and our correspondent. The parody was published in a medical journal quite recently.

PRACTICE IN CALIFORNIA AND WASHINGTON.

UBLY, MICH., March 11, 1901.

To the Editor:—Will you advise me as to the requirements for registration for the practice of medicine in California and Washington? To whom can I write for full particulars? J. S. C.

ANS.—The requirements were published in THE JOURNAL of February 23. There is a law now pending before the California legislature requiring examination, similar to that of Washington. The new law in Washington, just passed over the governor's veto, does not materially alter the situation so far as physicians coming into the state are concerned. For further information address the secretaries of the state boards, Dr. C. C. Wadsworth, 1104 Van Ness Ave., San Francisco, Cal., or Dr. W. G. Tucker, Port Townsend, Wash.

PRACTICE IN ALABAMA.

BUNCETON, MO., March 9, 1901.

To the Editor:—Please give me the laws regulating the practice of medicine in Alabama. C. P.

ANS.—An examination before the State Board of Examiners or before the county boards. A diploma is necessary if the examination is passed under a county board, but is not absolutely so before the state board.

PRACTICE IN IDAHO AND SOUTH DAKOTA.

SUGAR GROVE, VA., March 4, 1901.

To the Editor:—What are the medical practice laws of Idaho, Washington and South Dakota? H. C. C.

ANS.—In Idaho make application to the State Medical Examining Board, upon blanks which will be furnished, transmitting the diploma with an affidavit as to its ownership and identity, and that the applicant is a citizen of the United States. If the diploma is found satisfactory, the license will be given after examination, for which the fee is $25. For Washington see above. In South Dakota, graduation from a lawful medical college, after three full courses of six months each, no two in the same year, a certificate of good moral character and of not being a habitual drunkard, and a fee of $5 are required. If the graduation was prior to 1893, the requirement of a three-year-course is not insisted on.

HOUSEHOLD MEDICINE.

LEE CENTER, ILL., March 7, 1901.

To the Editor:—Will you give me the name, publisher and price of a household medical book suitable to place in the hands of a young woman, and which is in harmony with modern medicine and medical ethics. C. M. C.

ANS.—We do not know of any work on household medicine altogether suitable for endorsement.

PRACTICE IN INDIANA.

CHICAGO, ILL., March 10, 1901.

To the Editor:—Will you kindly give the requirements for the practice of medicine and surgery in Indiana? A. T.

ANS.—Applicants for licenses to practice medicine in Indiana must be bona fide residents of the county and state; must possess the necessary application blank from the county clerk, which, properly filled, with diploma and fee of $10, must be sent to the State Board of Medical Registration, Room 120, State House, Indianapolis, Ind. If satisfactory, the board will issue its certificate, and on presentation of this to the county clerk a license will be granted. If not satisfactory, an examination must be passed, for which the fee is $25. For further information as to rulings of the board, etc., address Dr. W. T. Curryer, secretary of the State Board of Registration, Indianapolis, Ind. A law requiring examination in all cases is now pending in the legislature.

PRACTICE IN WISCONSIN.

PHILADELPHIA, PA., March 12, 1901.

To the Editor:—Will you give me information as to the laws governing the practice of medicine in Wisconsin, also the name of the secretary, if there is a state board of medical examiners? E. A. R.

ANS.—In Wisconsin all persons commencing the practice of medicine and surgery must submit to examination or present a diploma from a medical college that requires at least three courses of not less than six months each before graduation, no two of the said courses to be taken within any twelve months. The fee for examination is $10, but if a satisfactory diploma is presented the fee will not exceed $5. The license must be recorded in the county where the practice is intended. A certificate from another state with equal qualifications may be accepted if the Board of Registration chooses. The Board of Medical Examiners holds regular meetings on the second Tuesdays in July, at the Park Hotel, in Madison; in October, at the Athearn Hotel, in Oshkosh, and in January and April, at the Hotel Pfister, in Milwaukee. All applicants for licenses should apply to the secretary, Dr. H. M. Ludwig, Richland Center, Wis., or at the addresses given, prior to meetings.

DRAINAGE OF LACRIMAL CANAL.

BOSTON, MASS., March 12, 1901.

To the Editor:—Please let me know the name of the doctor who first advised draining the lacrimal canal by means of a silk thread knotted together to a loop, which should be drawn, with the knot, through the canal once or twice a day. I have recently read about it, intended to relate it in a foreign journal, but can not find the doctor's name and residence. R. H.

ANS.—The article referred to was written by Erasmus A. Pond, and published in the *Medical Record* of February 2. It was noticed in THE JOURNAL of February 9, p. 469.

THE INDIVIDUAL COMMUNION CUP.

FORT WAYNE, IND., March 12, 1901.

To the Editor:—I am desirous of obtaining the name and address of the original experimenter in the individual communion cup agitation. He read a paper before the Section on State Medicine, at Philadelphia, in 1897, but I am unable to find the article. Would you kindly give me this address, or tell me where I can get it? L. P. D.

ANS.—The paper is probably that of Dr. Howard S. Anders, published in THE JOURNAL of Oct. 16, 1897. In it he gives the history of the original agitation and does not credit himself with the first publication in regard to it, though his own paper appeared in the same year—1894—as that of Dr. C. H. Forbes, to whom he refers. The address of Dr. Anders is 1836 Wallace St., Philadelphia, Pa.

PHYSICIANS AND THE AUTOMOBILE.

CHATTANOOGA, TENN., March 11, 1901.

To the Editor:—I notice an inquiry in the issue of THE JOURNAL dated March 9, from Dr. H. S. J., Lead, S. D., relative to the best automobile to be used in the physician's practice, and in answer I wish to say that I have tried the three different kinds of motive power and find that the steam vehicle is by all means the nicest and most practicable for use under all circumstances, because it can be depended on at all times. It is freer from noise than the electric or gasoline-propelled machine, will climb any grade and never balks, can be repaired by any mechanic, is easily and quickly

150 persons. In contrast to this experience of the non-transmissibility of tuberculosis from the progenitors, Goldschmidt cites twenty-eight families of various nationalities in which both parents were free from the slightest trace of tuberculosis. In 21 of the families, all the children died of tuberculosis between 15 and 35 years of age; in 5 others most of the children died, and in 2 others two children in each were affected with a tubercular affection of the bones. He points out that in 21 of these families the fathers were syphilitic. There were only 8 abortions in the record of all the families. He suggests that the paternal syphilis might have induced a predisposition to tuberculosis. He also is inclined to believe that the parental tuberculosis in the Madeira colony conferred a sort of immunity on the children.

Jolles' Improved Ferrometer.—Comparison of the readings of the hemometer and of the ferrometer affords valuable information in many cases, not to be derived from either alone. THE INDIVIDUAL COMMUNION CUP.

Fort Wayne, Ind., March 12, 1901.

To the Editor:—I am desirous of obtaining the name and address of the original experimenter in the individual communion cup agitation. He read a paper before the Section on State Medicine, at Philadelphia, in 1897, but I am unable to find the article. Would you kindly give me this address, or tell me where I can get it? L. P. D.

Ans.—The paper is probably that of Dr. Howard S. Anders, published in The Journal of Oct. 16, 1897. In it he gives the history of the original agitation and does not credit himself with the first publication in regard to it, though his own paper appeared in the same year—1894—as that of Dr. C. H. Forbes, to whom he refers. The address of Dr. Anders is 1836 Wallace St., Philadelphia, Pa.

PHYSICIANS AND THE AUTOMOBILE.

Chattanooga, Tenn., *March 11, 1901.*

To the Editor:—I notice an inquiry in the issue of The Journal dated March 9, from Dr. H. S. J., Lead, S. D., relative to the best automobile to be used in the physician's practice, and in answer I wish to say that I have tried the three different kinds of motive power and find that the steam vehicle is by all means the nicest and most practicable for use under all circumstances, because it can be depended on at all times. It is freer from noise than the electric or gasoline-propelled machine, will climb any grade and never balks, can be repaired by any mechanic, is easily and quickly gotten ready and not easy to get out of order. I have a steam vehicle with which I have climbed Lookout Mountain, Missionary Ridge, Walden's Ridge, been all over Chicamauga Park a number of times, been over all kinds of country roads, and fifty-six miles into the country on one charge. All of these trips were made without a single mishap. There is not the vibration or jolting peculiar to the gasoline-propelled machine, and it glides along as easily as could be desired. The electric vehicle can only be used successfully in cities, and then where stations for recharging are convenient. Gasolin can be gotten at any country store; that and water is all you need for a steam vehicle. I have made over thirty miles an hour with mine, have had it for nine months in constant use, while it is as good as new now and has cost me nothing for repairs. D. E. N.

New Patents.

Patents of interest to physicians, etc., February 19 and 26:

668,164. Making ammonia derivatives of saccharin. Leon Cerf, Lyons, France.

668,488. Amalgam squeezing machine. James V. Coleman, San Francisco, Cal.

668,466. Nurses' Companion Case. Margaret A. Taylor, New London, Conn., and P. A. Murphy, Lynn, Mass.

34,116. Design: Water-bag. Christian W. Meinecke, Jersey City, N. J.

668,671. Obtaining sodium sulphate from brines. Harry Baker and E. Haworth, Runcorn, England.

669,020. Spray tube for nebulizers. William and J. Boekel, Philadelphia, Pa.

668,911. Surgical instrument. George Ermold, Elizabeth, N. J.

668,636. Douche bench. William T. Gregg, Yonkers, N. Y.

668,647. Ecraseur. Max Jaenicke, Gorlitz, Germany.

669,034. Surgical instrument. James S. Manly, Cripple Creek, Colo.

668,823. Folding tongue depresser. Charles J. Pilling, Philadelphia, Pa.

668,929. Device for treating diseases of the ear. Mike Polich, Riverside, Cal.

668,661. Electric bathing apparatus. Oscar Schneider, New York City.

668,762. Disinfecting apparatus. Thomas N. Thompson, Scranton, Pa.

Copies of above patents may be obtained for 10 cents each by addressing John A. Saul, Solicitor for Patents, Fendall Building, Washington, D. C.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Feb. 28 to March 6, 1901, inclusive:

George W. Adair, major and surgeon, U. S. A., leave of absence granted.

Charles H. Andrews, captain and asst.-surgeon, Vols., recently appointed, and now in San Francisco, Cal., to report for transportation to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

J. Newton Boyce, acting asst.-surgeon, from duty on the transport *McClellan*, to San Francisco, Cal., to accompany troops to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

Louis Brechemin, major and surgeon, U. S. A., from Fort Logan, Colo., to San Francisco, Cal., en route to Manila for duty in the Division of the Philippines.

George E. Bushnell, major and surgeon, U. S. A., on expiration of his present sick leave, is assigned to duty at Fort Logan, Colo.

Jerome S. Chaffee, lieutenant and asst.-surgeon, U. S. A., recently appointed, is assigned to duty at Columbus Barracks, Ohio.

Harold W. Cowper, captain and asst.-surgeon, Vols., recently appointed, and now at San Francisco, Cal., to report for transportation to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

G. S. Driver, acting asst.-surgeon, leave of absence granted.

Matthew Leepere, captain and asst.-surgeon, Vols., recently appointed, and now at Fort Crook, Neb., to proceed to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Benjamin F. Pope, lieutenant-colonel, deputy surgeon-general, U. S. A., from duty at the Presidio of San Francisco, Cal., to proceed on or about May 1, 1901, to Manila, P. I., for assignment as chief surgeon of the Division of the Philippines.

Paul F. Straub, major and surgeon, Vols., now at San Francisco, Cal., is relieved from further duty in the Division of the Philippines and assigned to duty at Fort Crook, Neb.

Henry D. Thomason, major and surgeon, Vols., recently appointed, to proceed from Albion, Mich., to San Francisco, Cal., reporting to the commanding general, Department of California, for temporary duty, at the completion of which he will proceed to Manila, P. I., for duty in the Division of the Philippines.

Charles F. Williams, acting asst.-surgeon, from Yorkville, S. C., to temporary duty at Fort Screven, Ga.

Robert H. Zauner, major and surgeon, Vols., from temporary duty at Columbus Barracks, Ohio, to rejoin his station, Fort Du Pont, Del.

Navy Changes.

Changes in the Medical Corps of the Navy for week ending March 9, 1901:

Asst.-Surgeon O. M. Eakins, detached from the *Ajax*, when put out of commission, and ordered home to wait orders.

Surgeon F. J. B. Corderio, detached from the *New Orleans* and ordered to the *Buffalo*.

P. A. Surgeon R. Spear, detached from the *Buffalo* and ordered to the *Isla de Luzon*.

P. A. Surgeon R. M. Kennedy, detached from the *Newark* and ordered to the *Bennington*.

Asst.-Surgeon J. J. Snyder, detached from the *Isla de Cuba* and ordered to duty with a detachment of marines at Pollock, P. I.

Asst.-Surgeon M. V. Stone, detached from the *Isla de Luzon* and ordered to the *Buffalo*.

Asst.-Surgeon J. H. Payne, Jr., detached from duty at Pollock, P. I., and ordered to the *Isla de Cuba*.

Asst.-Surgeon E. O. Huntington, detached from the *Bennington* and ordered to the *Newark*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the twenty-one days ended March 7, 1901:

Surgeon George Purviance granted leave of absence for one day.

Surgeon C. T. Peckham, granted leave of absence for twenty days on account of sickness.

P. A. Surgeon J. A. Nydegger, upon expiration of present leave of absence, to report at Washington, D. C., for orders.

P. A. Surgeon J. A. Nydegger to proceed to Cape Charles Quarantine as inspector.

P. A. Surgeon H. W. Wickes, granted leave of absence for thirty days from March 11.

Asst.-Surgeon F. E. Trotter, upon being relieved by Asst.-Surgeon T. D. Berry, to proceed to Havana, Cuba, and report to the chief quarantine officer for duty.

Asst.-Surgeon T. D. Berry, relieved from duty at Havana, Cuba, and directed to proceed to Cienfuegos, Cuba, relieving Asst.-Surgeon F. E. Trotter.

Acting Asst.-Surgeon B. Y. Harris, granted leave of absence for ten days.

Acting Asst.-Surgeon W. H. Marsh, granted leave of absence for four days from February 27.

P. A. Surgeon T. B. Perry, granted leave of absence for thirty days from March 12.

P. A. Surgeon B. W. Brown, directed to report at Washington, D. C., for special temporary duty.

P. A. Surgeon J. A. Nydegger, to assume temporary command of the Cape Charles Quarantine station during the absence of Asst.-Surgeon C. W. Wille.

Asst.-Surgeon Taliaferro Clark, granted seven days' extension of sick leave, from March 8.

Asst.-Surgeon F. E. Trotter, relieved from duty as quarantine officer at the port of Cienfuegos, Cuba.

Asst.-Surgeon C. W. Wille, granted leave of absence for seven days from March 4.

Asst.-Surgeon T. D. Berry, detailed as quarantine officer at the port of Cienfuegos, Cuba.

[illegible]ong, relieved from duty in the Hygienic [illegible], D. C., and directed to proceed to New York City and report to Surgeon L. L. Williams, Immigration Depot, for duty.

Hospital Steward W. F. Macdowell, granted leave of absence for thirty days from March 20.

Hospital Steward F. S. Goodman, relieved from duty at Havana, Cuba, and directed to proceed to Washington, D. C., and await orders.

Hospital Steward Walter Newbern, granted leave of absence for thirty days from March 5.

Health Reports.

The following cases of smallpox and yellow fever were reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended March 9, 1901:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Feb. 23-March 2, 1 death.

California: San Francisco, Feb. 18, 8 cases.

District of Columbia: Washington, Feb. 23-March 2, 7 cases.

Florida: Jacksonville, Feb. 23-March 2, 3 cases.

Illinois: Cairo, Feb. 16-23, 6 cases.

Iowa: Ottumwa, Feb. 2-9, 1 case.

Kansas: Lawrence, Feb. 23-March 2, 2 cases; Wichita, Feb. 23-March 2, 12 cases.

Kentucky: Lexington, Feb. 23-March 2, 2 cases.

Louisiana: New Orleans, Feb. 23-March 2, 7 cases, 2 deaths.

Michigan: West Bay City, Feb. 22-March 2, 5 cases.

Minnesota: Winona, Feb. 23-March 2, 12 cases.

Nebraska: Omaha, Feb. 22-March 1, 5 cases.

New Hampshire: Manchester, Feb. 23-March 2, 27 cases.

New York: Elmira, Feb. 23-March 2, 1 case; New York City, Feb. 23-March 2, 64 cases, 11 deaths; Yonkers, Feb. 22-March 1, 1 case.

North Carolina: Charlotte, Feb. 1-28, 16 cases.

Ohio: Ashtabula, Feb. 23-March 2, 2 cases; Cincinnati, Feb. 22-March 1, 2 cases; Toledo, Feb. 23-March 2, 8 cases; Youngstown, Feb. 23-March 2, 2 cases.

Pennsylvania: Allegheny, Feb. 23-March 2, 2 deaths; Philadelphia, Feb. 23-March 2, 1 case; Pittsburg, Feb. 23-March 2, 4 cases.

Tennessee: Memphis, Feb. 23-March 2, 16 cases; Nashville, Feb. 23-March 2, 17 cases.

Utah: Salt Lake City, Feb. 23-March 2, 31 cases.

West Virginia: Huntington, Feb. 23-March 3, 1 case.

SMALLPOX—FOREIGN.

China: Hongkong, Jan. 15-22, 1 case.

England: Liverpool, Feb. 8-16, 2 cases; London, Feb. 8-16, 1 case.

Scotland: Dundee, Feb. 8-16, 6 cases; Glasgow, Feb. 15-22, 20 deaths.

Mexico: Vera Cruz, Feb. 19, 300 cases; Yucatan, Feb. 20, epidemic.

Russia: St. Petersburg, Feb. 2-9, 4 cases, 1 death; Warsaw, Jan. 26-Feb. 2, 8 deaths.

Turkey in Asia: Jaffa, Jan. 1-15, epidemic.

YELLOW FEVER.

Cuba: Havana, Feb. 17-24, 3 deaths.

The Journal of the American Medical Association

VOL. XXXVI. CHICAGO, ILLINOIS, MARCH 30, 1900. No. 13.

Address.

RECENT ADVANCES IN DERMATOLOGY WHICH ARE OF SERVICE TO THE GENERAL PRACTITIONER.*

L. DUNCAN BULKLEY, A.M., M.D.

Physician to the New York Skin and Cancer Hospital; Consulting Physician to the New York Hospital, etc.

NEW YORK CITY.

Four years ago,[1] when I last had the honor of presiding over this Section, my address was entitled "Notes on Some of the Newer Remedies Used in Diseases of the Skin." At that time I called attention to the very large number of new remedies which were continually presented to the profession, remarking that it was well "now and again to stop and weigh and try to estimate the value or worthlessness of the new and to see what of it should be added to our stock of old, and thus to recognize where true advance had been made." It is in this spirit that I again take up the matter, and I wish to present some of the more recent advances in dermatology, which are of service to the general practitioner.

In my former address I called attention to the fact, however, that it was not so much new remedies which are needed as it was better acquaintance with the diseases to be treated, and a more perfect knowledge of the means we already had; and also that in connection with newer remedies it is most desirable that very definite statements should be made, by reliable observers, of the exact conditions of use, and also the adverse results, as well as those which are favorable. I also remarked that as a rule general practitioners, I believe, were far more apt to try the newer remedies proposed than were those engaged in special practice. The specialist naturally weighs the true value of this or that new suggestion, and being fairly well satisfied with his present equipment, is less prone to rush into the new, except on very good evidence of its worth; and it may be added, much that is brought forward is often found to rest on very slender experience.

It would be quite beyond the possibilities of this address to attempt to cover the whole ground of recent advances in dermatology, and attention will be called only to such items as are likely to be of service to the general practitioner. We may, for the convenience of study, consider one subject under the three divisions of diagnosis, prognosis and treatment.

DIAGNOSIS.

Dermatitis.—Considerable progress has been made of late years in the way of recognizing various inflammatory conditions of the skin, under the general name dermatitis, and much that was formerly classed as eczema is now thus designated. All are now quite familiar with the dermatitis herpetiformis of Duhring, characterized by a variety of lesions, erythematous, papular, vesicular and bullous, which often very closely resemble eczema. The characteristic feature, however, is a grouping of the lesions and a recurrence of the attacks without any recognized cause. A recognition of the true nature of this often intractable disorder will often prevent much disappointment in the way of prognosis.

Dermatitis Medicamentosa.—Recent years have added very largely to the list of medicinal rashes or forms of dermatitis medicamentosa, and the number of drugs which have been observed to cause an eruption, in rare cases, is now very large. Time and space forbid dwelling on the features of the different appearances presented, but it may be interesting simply to mention the drugs which have been observed to produce skin lesions. These are aconite, antipyrin, arsenic, belladonna, boric acid, bromin, cannabis indica, carbolic acid, chloral, condurango, copaiba, cubebs, digitalis, iodin, jaborandi, mercury, opium, phosphorus, podophyllin, quinin, salicylic acid, santonin, sodium benzoate, strychnia, tar, turpentine, and perhaps some others. It is to be noted that the production of such effects is due to some idiosyncrasy on the part of the patient, for their occurrence is rare. It is well, however, for the general practitioner to bear the possibility in mind when eruptions of the erythematous type occur suddenly which do not quite correspond with well recognized affections.

Another form of dermatitis which recent advances have added is that due to the injury sometimes inflicted by the *x*-rays. This need not detain us here except to give the caution against a hasty favorable prognosis, for in many instances on record it has proved most rebellious, and in some cases has been attended with serious consequences.

Blastomycetic Dermatitis.—Still another addition has been made to the lesions classed under the same general name in the dermatitis blastomycetica, or yeast mycosis. This curious and rather rare affection resembles most the verrucose types of tuberculosis of the skin, but it is desirable to correctly diagnose it from these forms of lupus, as thorough and radical treatment offers very satisfactory prospects of cure.

La Grippe Rashes.—Very interesting additions to the list of acute erythematous skin lesions are those which have of late years been described in connection with la grippe; and often these will prove very puzzling to those not very well acquainted with diseases of the skin. In some instances the eruption is hardly distinguishable from measles, and in others it will be so confluent that scarlatina is closely simulated; sometimes it is impossible to determine the true nature of the eruption at once, and it is only by the concomitant symptoms that a probable diagnosis can be made. These la grippe eruptions are generally very short-lived, although sometimes they may persist and even recur, and from the catarrhal symptoms often present are not infrequently reckoned as second or repeated attacks of measles.

---

* Delivered before the Section on Cutaneous Medicine and Surgery at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Jour. A. M. A., Nov. 28, 1896.

Erythromelalgia, which was described by Weir Mitchell in 1872, has attracted some attention of late years, and is shown to be sufficiently frequent to merit attention. It is characterized by a flushing of the skin, mainly of the extremities and ears, with at times considerable burning pain. Often a single toe may be affected in such a manner that walking is difficult or impossible. It is particularly interesting, as the condition may be strongly suggestive of gout, or even of erysipelas. The attacks may be of brief duration, or the redness may persist for a considerable time, with no appreciable alteration of tissue. It is due to a nerve disturbance, either paralysis of the vasoconstrictors or an excitation of the vasodilators, and may be regarded as exactly the opposite condition to that which obtains in Raynaud's disease.

The pre-mycotic stage of mycosis is an interesting phase of skin lesion, happily very rare, which has been clearly established of late years. Long before the tumors appear, which were formerly supposed to constitute the affection, there may be a period of erythematous eruption in patches and circles which ultimately lead up to the fully developed malady. These erythematous lesions may often resemble erythema multiforme or erythematous eczema and may be very puzzling. There is generally not very much itching or subjective symptoms, and only the brownish-red circles or patches of varying size, generally first on the body and limbs, which either may slowly subside or remain and develop into the slightly protuberant, and later ulcerating, granulomatous masses which lead up to the distressing and sooner or later fatal disease.

Tuberculosis cutis has also obtained a full recognition of late years, and though comparatively rare, it may at times be of considerable interest to the general physician. While lupus vulgaris is also recognized as due to, or at least associated with, the presence of tubercle bacilli, the name, "tuberculosis cutis," is most commonly given to the warty masses seen from time to time, principally about the hands and face. While lupus probably comes from the infection of the bacilli through the medium of the lymphatics and blood-vessels, the tuberculous cutis verrucosus has to do with primary local infection, and the disease tends to remain more or less local, or increases very gradually. When removed effectively the disease generally remains absent, a healthy cicatrix taking its place. It is most commonly seen in butchers, and also in anatomists, and in those having much to do with tuberculous patients, as in laundresses who have cared for their clothes.

Ringworm.—The advances in the study and knowledge of ringworm, while not yet resulting in any very startling improvement in therapeutics, should still be of interest to practitioners. It has been found that what has hitherto passed as a single disease probably represents a number of distinct affections due to parasites which may be quite different in their microscopic appearance, behavior under cultivation, and also in their clinical effects on the skin. A large share of the eruption on the heads of children is due to the small-spored fungus, which rarely attacks adults; while the forms of ringworm found on the other portions of the body are due to one or two different varieties of trichophyton, which also readily affect adults. It is claimed that the varieties causing suppuration, as seen mainly on the bearded face, are derived from animals. It is interesting to determine, microscopically, whether the scalp disease is caused by the microsporon or the megalosporon, as the former is much more obstinate to treatment and a more unfavorable prognosis as to duration is necessary.

PATHOLOGY.

In the pathology of skin diseases there has still been considerable activity of research, and clearer views are obtained each year in regard to many affections.

Eczema has been the object of much consideration, and there have been several notable studies and discussions in regard to its true nature, while the old question as to its local or constitutional origin has been repeatedly considered. One writer (Larrede) has been very strenuous for a parasite origin of much that is called eczema, while another careful thinker (Leslie Roberts) argues strongly and rightly, as we believe, in the direction of the very great importance of the resistive power of the skin in the direction of nervous control.

Seborrheic Eczema.—Very great advance has been made in the full recognition of seborrheic eczema, with which the name of Dr. Unna will always be associated. While it is not definitely proven that it is due to a micro-organism, this is about accepted by most dermatologists, and the almost specific control of it by resorcin and sulphur is one of the most satisfactory advances in dermatology, which every practitioner may share.

Alopecia Areata.—Interesting and elaborate studies have been made by Sabouraud and others in regard to the pathology of alopecia areata and much evidence has been brought forward, both in writing and discussions in regard to its parasitic and its nervous origin, and the true nature of all cases of this interesting disease is not yet established. The opinion is prevailing more and more, however, that both views are correct, and that there are probably two affections, closely resembling each other, one caused by a micro-organism and the other of nervous origin. This is not at all surprising when we consider how closely many other skin lesions of quite different characters resemble each other, as lupus and tubercular syphilis, psoriasis and ringworm, etc.

Role of Pus Organisms.—Many studies have been made of late years in regard to the rôle of pus organisms in the production of skin diseases, and many have been very strenuous in regard to their pathologic influence. Elliot[2] has made a careful review of the literature, and his conclusions must be somewhat disappointing to the ardent supporters of micro-organisms as a sole cause of disease—for he finds that while the pyogenic organisms, the staphylococci and streptococci are in general the cause of suppuration, they are not the only cause. In a large proportion of cutaneous diseases, primarily or secondarily suppurative, no constant pyogenic serum organisms have been found and inoculation experiments have usually been negative or have failed. This coincides with what had been expected by those who take the broadest view of dermatologic medicine, and who realize that vitality and innervation play an important part in the production and cure of skin affections as well as those of other organs.

Dr. White, Jr., of Boston, has made some very interesting studies in regard to the rôle of staphylococcus in skin diseases, and while he demonstrates that the pus cocci were found in a variety of pustular lesions, he acknowledges that the form and variety of the lesions depend upon other elements. No one can rightly deny the power of micro-organisms to produce disease, for the results of aseptic surgery are incontrovertible, but there is great danger in connection with diseases of the skin lest local pathology lead to a neglect of the more important consideration of the soil on which the germs flourish; a striking illustration of the bearing of this remark is found in the change of opinion which has come over the medical world in regard to the relative importance of attention to the microbe in tuberculosis, as compared with the more important elements of the nutrition and hygienic condition of the patient. Pus organisms, as also an infinite variety of bacteria, are almost omnipresent, and when opportunity offers, pathogenic organisms do germinate and their toxin causes disease. But, on the other hand, the very omnipresence of these germs and the relative infrequency of their action certainly shows us that the truly wise physician should look to more than the local cause and seek to discover and remedy the underlying cause in each case. This points once more to the wisdom of the precept that it is often the patient who is to be treated rather than the disease by a specific name.

---

[2] Elliot: Jour. of Cutan. and Genito-Urin. Dis., February, 1900.

THERAPEUTICS.

Very much has been reported of late years in the line of therapeutics of diseases of the skin, and if one should adopt the various suggestions appearing in literature there would be a never-ceasing change of methods, which certainly would not be of service in the practical management of cases. It sometimes requires not a little determination to resist the apparently plausible assertions of writers in regard to the value of this or that new remedy or procedure. It must ever be remembered that cases of the same disease often differ very greatly in their behavior under treatment, and also that remedies or measures often succeed much better in the hands of the one who proposes and uses them than they may do when employed by another. Every workman knows his own tools, and better work can often be done by a skilled workman with poor tools than by a poorer artificer equipped in the best manner. From a very considerable experience with new remedies and old, I would therefore utter a word of caution against the too ready acceptance of "therapeutic hints" which are so overabundant in this day of intense restlessness in every field of human activity.

Newer Remedies.—In looking over my address of four years ago I find a number of the newer remedies there mentioned which have well stood the test of time since that date, and some which are there mentioned more or less favorably which I do not now advocate. I will not consume time in going over all these again, but may make a few remarks about some which seem appropriate.

Resorcin and ichthyol have more than held their own, and all that was said of them still holds good, and more could be added if desirable. I do not know whether much can be said in favor of thiol and tumenol, then mentioned; I seldom employ them or hear of their use, as I have never felt satisfied that they were better than ichthyol—if this can be obtained pure, which is often difficult. Alumnol, betanaphthol, aristol and europhen hold their own, and menthol is often of great value in controlling itching. Peroxid of hydrogen is used with increasing confidence in connection with many ulcerative conditions of the skin, and is also of value in chloasma, and to bleach superfluous hair on the face or elsewhere, and appears to have a measure of effect in destroying the life of the latter. Camphor-chloral and camphophenique are still regarded as valuable antipruritics, and lanolin, vaselin, cosmolin, albolene, etc., are in constant use. The various dusting powders made from stearates, as also the dolomol preparations have their uses under certain conditions and are still regarded as valuable. The effort to produce adherent dressings to the skin, alluded to in my former address, has not been as successful as was hoped, and the results from plasters, gelatin dressings, etc., are not always as satisfactory as could be desired, although some of the prepared and medicated plasters serve an excellent purpose in certain chronic and hard conditions of the skin. Finally, medicated soaps, which were there alluded to, are slowly assuming their proper place in dermatology, which will never be a very large one; under suitable conditions they are of service, but in inexperienced hands there is more danger from their injudicious use than is commonly appreciated.

Phototherapy and X-Rays.—Among the newer therapeutic agents from which much has been expected perhaps the first which should be mentioned is that of light, as found in the *x*-rays and the so-called Finsen phototherapy. It is perhaps too soon to form a correct opinion of the real value of this means of treatment, and some of the earlier reports have been so extravagantly favorable that very strong hopes were raised that in this we had at last a successful means of combating that rebellious disease, lupus. But when we recall the enthusiastic reports attending the earlier use of Koch's tuberculin in lupus, and consider that now that method of treatment is practically discarded, there is reason to fear that the hopes now held out by this new method may also prove illusory.

It is hardly necessary here to describe the apparatus or the exact method of treatment, suffice it to say that it consists in means whereby the direct rays of the sun somewhat concentrated and deprived of its red or heat rays are made to impinge upon the affected area. Both the direct rays of the sun and those obtained from an electric arc-light have been used, and many reports have been given in which the disease has gradually shrunken away and disappeared. Whether the claimed cures will be permanent time alone will show, and as far as I can learn, there are not many dermatologists who are enthusiastic over the procedure. In the cases treated the patient has been subjected to the altered rays of light for several hours at a time, and daily sittings are generally required, while the treatment lasts over some weeks. The treatment has been especially developed by Finsen, of Copenhagen, and Dr. Hopkins, of Brooklyn, has installed an apparatus for this phototherapy, but I have not yet learned of any results obtained there.

Therapy of Lupus.—The *x*-rays have also been used for lupus, and a number of writers have reported cases of apparent cure, but it is yet too soon to be certain as to ultimate results.

In connection with this treatment of lupus should be mentioned the excellent results which have been reported by Lang, of Vienna, and many others, from the complete excision of the disease under perfect aseptic conditions, with subsequent treatment by plastic surgery or skin-grafting. The reported results are so satisfactory that there should be no hesitancy in accepting this as the quickest, and in many respects the most satisfactory, method of dealing with certain cases of this most rebellious disease.

Treatment of Lupus Erythematosus.—The treatment of lupus erythematosus has also received considerable attention of late years, but unfortunately no very great advances have been made; although phototherapy has been reported to have yielded good results in this disease. Whitehouse has recently reported the cure of lupus erythematosus with the internal use of iodoform, one grain three times daily, and I have seen great apparent benefit from its use in this disease. The number and variety of local measures which have been recommended during the past few years show that we are yet far from having a certain remedy for the disease; all of them have the object of altering the vital relations of the tissues. One which is well worth trying, and which I have seen of service, is the local use of arsenic, either in the form of diluted Fowler's solution, or a solution of arsenious acid, beginning with two grains to the ounce in water and increasing the strength, so as to produce some moderate cutaneous excitation. After its use a mild, soothing lotion, such as that of calamin and zinc, is applied.

The current literature of the past few years is very full of suggestions of various kinds in regard to the treatment of very many of the common diseases of the skin, but unfortunately there are but few of them which are of such special and certain value as to warrant much detail here. We may mention a few of the most valuable.

Arsenic in Eczema.—Some writers have again brought up the almost specific control which arsenic will have over eczema in small children, when given freely and for a prolonged time, as the present writer showed some time ago; it seems to have less effect on the disease after the age of 5 years. The present writer would call especial attention to the value of milk in connection with the treatment of eczema if used in exactly the right manner, as detailed before the Association two years ago. In cases of neurotic eczema the results will often be very striking, if the method is accurately followed. This consists in taking a tumblerful of milk, *slightly warmed, one hour before each meal,* followed, if possible, by a rest of half an hour in a darkened room. The milk should be taken pure and alone, no atom of other food being taken with or soon after it, and care being exercised that the stomach is entirely free from food or medicines previously taken. When used in this way the milk acts as a powerful nerve tonic, and neurotic eczema will often yield much more rapidly and satisfactorily than without it.

Local Therapy in Eczema.—Very much has been written of late years in regard to the local treatment of eczema, and to even briefly enumerate the various remedies and measures which have been proposed would more than consume the time alloted to this address. Undoubtedly for the different stages and phases of this protean eruption very varied treatment may at times be required, but it seems suitable to utter a word of caution against the too ready acceptance of much that is prescribed.

Lassar's paste (zinc oxid, ʒii; pulv. amyli, ʒii; vaselin, ℥1; m.), to which may be added camphor, salicylic acid or resorcin, 2 to 4 per cent., or even more, is certainly a very valuable addition to our means of combatting subacute eczema.

The various gelatin-glycerin preparations, applied so to form a firm, adherent coating on the part, are still extolled by many, but the present writer has not of late made great use of them. The following is one of the latest formulæ, which should be of service in certain conditions:

℞. Gum tragacanth ....ʒiiss
Gelatin optim. ....ʒii
Glycerin ....ʒvi
Thymol ....gr. ¼
Aquaæ destil. q. s.

Soak the tragacanth and the gelatin each in ten ounces of water over a steam bath for twenty-four hours, strain through muslin and make the final quantity up to twelve ounces with water.

Ichthyol, resorcin, salicylic acid and nearly every remedy used in dermatologic practice can be incorporated with this. It is applied like an ointment, or spread on *with a brush lightly,* and on drying gives a plastic, protective film.

Picric acid has been much praised of late, used in a saturated solution, pure or somewhat diluted, painted over acute and subacute eczema. It causes great smarting at first, which ceases, however, in ten or fifteen minutes, giving place to a sense of relief.

Permanganate of potassium, in a 2 or 3 per cent. watery solution, painted over the parts and allowed to dry on, is also a valuable antipruritic, as pointed out by the present writer some years ago.

Treatment of Syphilis.—This has been the subject of much consideration of late years, and really very diverse views may be found given by reliable observers, but mercury is still the acknowledged remedy, with iodin as an adjuvant. The question is repeatedly discussed as to the date of beginning mercurial treatment, and the duration and regularity of medication, and while some argue for only symptomatic treatment, on the recurrence of specific lesions, the weight of judgment seems still to be in favor of early measures as soon as the diagnosis is definitely established, and prolonged treatment, even to three to five years, with occasional breaks.

The hypodermic injection of various preparations of mercury has had very strong advocates during the past few years, and thousands of injections in hundreds of patients are reported with favorable results, and this both in the early and late stages of the disease. Its advantages are that: 1, it is an active remedy which can be regulated perfectly; 2, it avoids disturbing the digestive tract; 3, it avoids publicity in using remedies; 4, it is sometimes surprisingly curative when other measures have seemed ineffective. Its disadvantages are mainly the pain and occasional inflammation and abscess. Each of the different preparations of mercury for hypodermic medication has its advocates, and the bichlorid, calomel, "grey oil," and salicylate of mercury are about equally supported by testimony.

A somewhat new method of applying mercury through the skin has been introduced by Welander, and is worth mentioning. Acting on the idea that a certain amount of the good effect in mercurial inunction arises from the inhalation of vaporized mercury, he has devised a method by which it is worn next the skin on the chest. This is in the form of a bag fifteen by twenty inches in size, which is worn like a chest protector. On the inner side about a dram of mercurial ointment is applied every day. A fresh bag is used every week or so, and the patient may bathe daily. It is said that absorption of mercury takes place very quickly in this way, with great benefit to syphilitic lesions, which might indeed be expected, as it corresponds closely to the method of treating infantile syphilis with mercury on the inner surface of the abdominal band.

A new preparation of iodin, iodalbacid, has been introduced which, given in doses of from 3 to 5 grains daily in capsules, is said to have been very effective in cases of syphilis where iodid of potassium was badly borne.

It would be interesting to continue a consideration of the therapeutic advances in dermatology which are of value to the general physician, but already the proper limits of this address have been overstepped and I must stop. But the subject is not all exhausted and there are many items which properly should be mentioned; and my only hope is that something which has been said may be the means of exciting a more lively interest in the subject of diseases of the skin, and may lead some one to more seriously seek to know and recognize this class of affections and their proper and best therapeutic measures. Dermatology is an inviting, though difficult, field, and there is certainly no short cut to its thorough mastery, but although all can not hope to compass it entirely, a reasonable amount of study and observation, with judgment, will enable the general practitioner to utilize many of the advances which are continually being made in this branch.

In conclusion allow me to say a few words in regard to the Section on Cutaneous Medicine and Surgery, which is a part of this great national organization of medical men. Since the beginning of this Section the effort has been, on the part of the officers, as far at least as I have had anything to do with it, to make it such as would be of value to the general practitioner and to enlist his co-operation, both in the matter of the preparation of papers and attendance. This is not a gathering of specialists in dermatology; indeed, relatively few of the dermatologists of the country have ever attended any of its meetings. The American Dermatological Association is for such, as are also certain local societies. It is true that all the papers presented have not always been such as would greatly interest the general practitioner, nor is this the case in any other of the Sections. And yet, during all these years the skin section has been very poorly attended, and it has been hard to interest the profession in it. I speak of these things both for those now present and for those who may perchance read this later. Those of us who are well versed in the subject should, I think, not introduce too much of the rare and difficult, but rather topics which may be of general interest, and the same in the discussions. I would also have general practitioners present such matters as are of interest or difficult to them that they may be here discussed, and I would also have general practitioners take part in the discussions, even though they may not be able to vie with the specialist in accuracy or freedom of expression. I repeat it, that this Section should be the field where the profession can bring the difficult and knotty problems in dermatology and receive the aid of those perhaps more familiar with the branch.

DISCUSSION.

Dr. H. C. Yarrow, Washington, D. C.—I was particularly impressed with the remarks concerning the use of medicines by hypodermic injection instead of by *the mouth*. I have been using, for the last four or five years, in cases of constitutional syphilis, hypodermic injections, and have found sozo-iodol of mercury to answer best. I have used other preparations, but none which gave so little pain. If the part is rendered anesthetic, and care is taken to drive the needle deeply into the tissue, the insertion may be accomplished without pain. Out of hundreds of cases in which I have used this treatment, to the exclusion of materials by the mouth, I have never had a bad symptom or abscess and very few cases in which I have failed to cure the patient. I am very glad to hear this matter mentioned, because if the members of the profession at large knew what great value there is in the hypodermic injection of mercury, according to my experience, they would largely abandon the use of remedies by the mouth. The proper mode is to commence with ¼ gr. and run the amount up according to the idiosyncrasy of the patient. I have given as much as 1.5 gr. at a dose without trouble.

A Member—How often?

Dr. Yarrow—At the commencement of treatment in the way I have mentioned, it may be given twice or three times a week for several weeks. After perhaps four or five weeks, if the patient is doing well, it may be given only twice, until finally you give one hypodermic injection weekly, then one in two weeks, and so on. I never cease this treatment under two years. Certainly, in my hands, the results have been more gratifying than anything I have ever used.

Dr. M. B. Hartzell, Philadelphia—I wish to refer to the use of quinin in large doses in the treatment of lupus erythematosus. I do not recall who proposed it, but I have used it in a number of cases with good results. I have not cured any patient with it, but I have seen such marked improvement follow promptly on its use that I can not but believe it exercises a beneficial influence on the disease. I do not know any remedy given internally which produces such a beneficial and prompt effect. I have given 25 to 30 grains a day. There has been marked improvement up to a certain point, but later the improvement ceases. One patient told me that while she was taking the quinin, the eruption was held in check, but as soon as she stopped it, it spread.

Dr. S. Sherwell, Brooklyn, N. Y.—There is one point familiar to those reading dermatologic literature, and that is the result of Finsen's method of applying sun-rays, particularly in lupus vulgaris. One who studied the method under Finsen, was a member of his clinic and received unusual privileges, did not report favorably on it, but did on a mode of treating lupus by saturating pointed sticks in the acid nitrate of mercury and carbolic acid and then introducing them, thrusting them into the lupus patches and making a person look a little bit like a hedgehog. They are cut off at or about the surface of the skin, and then a plaster put on to hold them in position. I reach the same favorable results in my experience by curetting the lesions, and then applying still more lightly the nitrate of mercury and carbolic acid. I do not look upon lupus as an incurable disease.

Dr. W. R. Inge Dalton, New York City—I desire to add my testimony to what the Chairman has said in reference to the treatment of eczema. I took note of his suggestion four years ago, and he mentioned at that time beta-naphthol, also jaborandi in combination with calomel. I combined all three, but used pilocarpin, the active principle of jaborandi, instead of jaborandi, and found it to be of vast benefit. Two years ago I heard Dr. Bulkley allude to this milk theory of his—one glass before each meal, and, I believe he stated at that time, a glass at bedtime. That mode of diet is simplicity itself, and very commendable, and when the patient follows the directions faithfully, as I have tried it in many cases, the result is very satisfactory.

Dr. William L. Baum, Chicago—In the treatment of erythematosus I use applications of arsenic solutions, one-half of 1 per cent. solution of sodium arsenate. With this method, three cases which I have treated in the last five years not only have shown marked improvement, but in two the disease has not shown in the last year and a half. Regarding hypodermic injections in syphilis, I doubt whether anybody has used it more consistently and in a larger number of cases than I have in the last ten years. This treatment is certainly of great value in certain conditions where it is necessary to produce a profound result in a short time. I quite agree that the injections should be intermuscular. As to the necessity for rendering the point of injection anesthetic, with injection of bichlorid, it is not painful; the trouble comes after the patient has had his injection a short time. And there is no necessity for the appearance of abscesses after this injection. It is probably the most satisfactory and most successful in most patients.

Dr. M. T. Corlett, Cleveland, Ohio—I wish to corroborate what was said relative to lupus erythematosus. Last year, in the treatment of this obstinate disease, I followed out the treatment of large doses of quinin. The disease respo readily to this drug, but to be successful it must be given in large doses. So I have found 30 grains a day necessary to produce marked effects. I have found also that it produces its effects only up to a certain point; I have yet to see a patient entirely cured. I have also found the local application of alcohol, which I have used for the last year or two, gives good results. With these applications I have accomplished better results than before in the treatment of lupus erythematosus. With regard to the treatment of syphilis by hypodermic injection of mercury, I agree with Dr. Baum, using it deeply injected, and I do not think it is applicable to all cases. I do not use it as a routine. The old methods by the mouth or inunctions—which in private practice is objected to by many—are better measures. But there are some cases which require quick treatment, and muscular injection is the best because in a few days one can get a decided effect. In many cases inunctions are not objectionable, and where the patient can be induced to follow out that treatment, it is also of value.

HYPERACIDITY A CAUSE OF SKIN DISEASES.*

W. R. INGE DALTON, M.D.

NEW YORK CITY.

A year ago I wrote: "I have demonstrated to my own satisfaction that some skin affections are due to a nutritive disturbance, a defective degenerative metabolism, owing to which there ensues deficient utilization of nutritive substances conveyed to the tissues; producing a lethargic condition of the skin, an inefficient stimulation of the nerve twigs supplying the sudoriferous glands; that bacterial agencies cause septic and putrefactive changes in the alimentary canal and that inanimate toxins maintain selective affinities for the tissues, exerting their action upon the primordial protoplastic groups of cells. I am inclined more and more to think that the bond which connects the diatheses of the dermatoses with gout, rheumatism, arthritis, diabetes, and asthma, is generated by indiscretion of diet—and hic est mucro thesis meæ": *that the chyme passing in a hyperacid condition from the stomach, through the pylorus, into the second stomach, entails such increased labor upon the duodenum that its contents can not be rendered sufficiently alkaline for physiologic metabolism.*

Here is the starting-point—this acid dyscrasia, as I believe, the inevitable *fons et origo* of the pathologic lesions, which lead certainly to nearly all diseases of the skin, save the contagious exanthemata. The nidus is here furnished for the elaboration of the pabulum upon which the micro-organisms feed and propagate, thereby favoring organic fermentative changes throughout the ileum and large intestine, culminating in stasis of cellular action, cutaneous obstruction, and peripheral atrophy; visceral, cerebral, pulmonary, or cardiac lesions. The hyperacidity also inhibits the functional action of the glands of Lieberkühn and Brunner. The duodenum is the paramount reflex center for the entire intestinal tract; the pancreatic and biliary fluids pour into it; the par vagum connects it closely with the central nervous system; the solar plexus associates it with the sympathetic; the splanchnic, with the filaments of the spinal cord, as well as the thoracic center, and with the plexuses of Auerbach and Meissner—the one of the muscular coat, the other with the mucosa. It is here that iron is absorbed and taken up by the transport cells, combined with albuminous bodies, to be carried into the circulation, and it is the receptacle for an immense amount of blood. These physiologic and anatomic endowments all demonstrate the supreme importance of keeping a watchful supervision, so that the functional action of the duodenum may not be impaired. It is rather coincidental that whenever there are extensive excoriations or lacerations, or burns, involving a large amount of space, there follows ulceration of this organ.

It is contended that the infection caused by bacilli goes from the tonsillar crypts directly into the circulation, but I hold to my theory as being more tenable—it is that the chyle is emulsified while undergoing pancreatic digestion in the alimentary tract, and these minutely-divided products transport the pathogenic germs immediately through the lacteals, without causing infection locally into the vena cava; the lymph of the lymphatic system, with the micro-organism enveloped in the chyle, goes directly through the thoracic duct into the left innominate vein, and from the innominate into the venous circulation, through the right heart to the lungs, setting up infection there, by retarding oxidation, or they pass on with the blood, to find access to the cutaneous system, where, if they find suitable culture-media (the nidus upon which they feed) their deleterious action commences; leading to an aberrant cellular activity, caused by changes in contiguous surrounding fluids, unless the phagocytes succeed in devouring them.

We meet with brilliant clinical results in the treatment of summer diarrhea in children—those cases where the stools emit a characteristic odor, showing albuminoid decomposition or acid fermentation, when we feed them upon a low percentage, pasteurized, highly alkaline fresh milk, *without exhibiting even one grain of medicine.*

There are other etiologic factors, such as the physiological process of reflex irritation, of dentition, hard fecal accumulations, pregnancy, epileptiform convulsions, shock, worms, phimosis, adenoids, etc., causing temporarily, tendencies to morbid conditions of the skin, but the causa causam—the main etiologic element—I proclaim it boldly, is hyperacidity of the chyle in the duodenum; to this is due many ills to which the skin is heir. I have based my treatment upon this etiologic theory and have met with phenomenal confirmation of its efficacy, in my service at the Metropolitan Hospital, and in private practice, in the various forms of eczema, pemphigus, etc. I prescribe:

R.	Naphthalin	gr. i
	Ipecac	gr. i
	Charcoal	gr. iss
	Calomel	
	Strychnia	
	Pilocarpin	
	Arsenious acid, āā	gr. 1/100

The naphthalin causes antisepsis and inhibits the action of micro-organisms through the ileum and large intestine, thereby arresting organic fermentative changes. The charcoal, besides being a splendid antiseptic, converts the anaerobic condition of putrefaction into compounds which are not destructive to the tissues; the mercury, whether it acts upon the liver or not, destroys the bacterial forms in the duodenum and jejunum and lowers the blood pressure, thereby accelerating capillary circulation, thus favoring digestion and obviating putrefaction; the pilocarpin and ipecac exerting, at the same time, their influences upon the sweat glands and lymphatics; and finally the strychnin toning up the vasomotors and the whole cutaneous nervous system. I do not claim that my remedy will kill the pathogenic microbes in every instance, but it *does* limit their morbid energies, and by so doing gains time for the conservative remedial agencies of the organism to perform their normal function. Some pathogenic bacteria, which elaborate toxins, or ptomains in septic or putrefactive conditions, are otherwise entirely innocuous. We can unquestionably lessen their virulent activities by altering the environments of the pathogenic organisms. The stomach must be in proper condition, suitable diet enjoined, otherwise, no matter how specific the remedy may be, if the sympathetic nerve-centers, governing metabolic processes, standing for assimilation, are held in check from ptomain intoxication, no good effects can follow. Obstipation of bowels must in every case be combated, and as uric acid accumulates in the blood, as proved by Horbaczewski and Weintraud—that it is formed wherever living matter exists by the dissimulation of albuminoids—and as Kossel demonstrated, passing through the intermediate stages, nuclein, xanthin to uric acid. I generally follow my tablets by giving sulphate of magnesium, carbonate of lithium, and phosphate of soda in an effervescent form, the next morning.

---

*Presented to the Section on Cutaneous Medicine and Surgery, the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

It is only recently that the term eczema parasiticum has been tentatively admitted to the nomenclature, but not yet added to the classification of dermatology—*causa latet: vis est notissima.*

101 Convent Avenue.

DISCUSSION.

Dr. W. S. Gottheil, New York City—I am sorry that I did not have a chance to hear the first part of Dr. Dalton's paper. There is a marked tendency now on the part of dermatologists to pay more attention than formerly to the influence of general systemic conditions on their etiology, and it is a tendency in the right direction. The paramount influence of the Vienna school led to the very general acceptance of their ideas of the exclusively local nature and origin of most dermatoses; but that influence seems to be declining, and we are turning more and more to the opinions which have always maintained their ground among the French dermatologists, and are paying more attention to the general systemic condition or diatheses which, in some instances, at least, are the basic facts of their etiologies.

Dr. S. Sherwell, Brooklyn, N. Y.—I am in perfect accord with the general sentiment of the paper, while perhaps not entirely so with the theory of the Doctor, as to the way it is involved. I do most thoroughly believe, however, that the hyperacidity of the blood, caused in my mind by defective assimilation and equally defective metabolism, is at the root, and acts as *fons et origo* of many cutaneous diseases, as notably in eczema and psoriasis, etc. I am glad that there seems to be—the Doctor's paper being one evidence—a reaction against the dogma of a certain school that everything pertaining to skin diseases should be almost entirely regarded as local manifestations and be so treated. I am glad to see that there is more common sense and a larger degree of attention paid to systematic alterations and visceral complications today in general dermatology, diagnostic as well as therapeutic.

Dr. L. Duncan Bulkley, New York City—I have long maintained that we are wrong in looking so wholly, as has been done in time past by many, for purely local causes for skin diseases. Perhaps some will remember that in my paper yesterday I quoted Dr. George Elliot, who, five or ten years ago, was almost a pure localist, very full of foreign views, and very strong in his advocacy of purely local causes, and last year he expressed the opinion that the causes of pustular lesions were more sympathetic than local. The Doctor is getting nearer the truth when he calls attention to hyperacidity—another name for the "gouty state," etc.—and we will have greater success if we take into consideration internal conditions. Each one of these remedies named by Dr. Dalton has certain qualities, which combined will accomplish what he claims. The prescription offered is a valuable suggestion.

Dr. W. R. Inge Dalton, New York City—Each and every article in that prescription has been thought out from what has been said by eminent dermatologists. I have been giving that remedy for the last three years, and in 162 tabulated cases of eczema, acne, pruritus and pemphigus, taking together all the cases I have had in my own practice, and in my service in the Metropolitan Hospital and Dispensary, in all these cases I have not had one single failure. Dr. Sherwell has asked me if I employ topical applications. I use them in every case, such as zinc stearates, with carbolic acid or salicylic acid or menthol, to allay itching, in eczemas, with appropriate dressings; also in all forms of dermatitis, but I do not rely upon them as formerly, only as a palliative to relieve distressing symptoms.

ACUTE SUPPURATIVE FOLLICULITIS OF THE SCALP.*

WM. S. GOTTHEIL, M.D.
NEW YORK CITY.

The inflammatory affections of the hair follicles are still, it must be admitted, an unsatisfactory chapter in our dermatologic text-books. Some hardly mention them at all; and those who do practically admit, with James Nevins Hyde, that "there exists a whole series of interesting and important inflammatory affections of the hairy parts which have not as yet been distinctly differentiated from each other, or the whole series from all others."

Periodical literature, on the other hand, contains the records of many cases of follicular inflammation of the scalp; and the great variety in their terminology is a good index of the confusion that still prevails upon the subject. Quinquaud has described a "Folliculite Déstructive"; Brocq a "Folliculite et Perifolliculite Décalvant"; Besnier an "Alopécie Cicatrisante Innominée"; Lailler an "Acne Décalvante"; Leloir an "Conglomerate Pustular Perifolliculitis"; Unna an "Ulerytnema Sycosiforme"; Sack a "Dermatitis Perifollicularis Atrophicans"; Lukasiewicz a "Folliculitis Exulcerans"; and Tommasoli a "Bacillogenous Sycosis." And this by no means exhausts the list. The American cases of follicular inflammation have been recorded by Fox, Holsten, Jackson and others.

There can be no doubt that several distinct affections characterized by follicular or perifollicular inflammation of the glandular structures of the scalp, and leading, with or without suppuration, to loss of hair and atrophic changes, are included in this list. The analysis and classification of these cases is a task that must await a wider experience and more exact records. Certain prominent characteristics are, however, noticeable in almost all of them. They are chronic, with a duration extending over months and years; they affect localized or isolated areas of the hairy skin; and they are rarely frankly suppurative, the inflammatory process being subacute, and the resultant atrophy interstitial in character.

If I now venture to add another to the recorded cases it is because it presents a clinical picture of a folliculitis of extreme acuity, pyogenic in character, universal in distribution, causing complete loss of hair, and not resulting in atrophy of the pilous structures. In the literature accessible to me I find mention in but two instances of a similar affection. R. Sabouraud,[1] under the designation of "Impetigo Pustulosa Peripilaris," describes an affection which he believes to be identical with the "Impetigo Pustulosa" which Boeckhart first recorded in 1887. It occurs usually upon the head, and always in connection with the hair. It begins

[1] Annales de Dermatologie et de Syphilographie for 1899.

with peripilar abscesses, of which there may be hundreds, which never get bigger than a pea, and never become confluent. They form rapidly, many appearing in a single night. The only premonitory symptom is a painful swelling of the cervical glands. Sabouraud believes the affection to be intimately related to acne suppurativa and necrotica, folliculitis, furunculosis, etc.

At the London Dermatological Society, June 9, 1899, J. J. Pringle showed a case in a 16-year-old boy having an eruption of the scalp beginning as red macules. In six weeks, in spite of treatment, the scalp was covered with crusts and scabs, removal of which showed every follicle to be the seat of an acute suppurative process, and the process resulted in the formation of deep scars. Each hair sat in the center of a yellow pustule. It looked like favus, said Pringle, yet examination revealed only the presence of numerous heaps of staphylococci. Crocker was of the opinion that the affection was a form of the dermatitis papillaris capillitii of Kaposi.

Of the two cases on which this paper is based, one only could be observed with sufficient care and for the requisite length of time. The first one was in a child of 2 years, and was apparently similar in all respects to the case recorded below. But the patient disappeared after a few visits to the clinic, and the history is too incomplete for recitation here. The second case was under observation for nearly a year, until long after all traces of the malady had disappeared and the parts had returned to a normal condition.

Lena G., a Russian, aged 16, came to the clinic on Feb. 18, 1899. She was apparently in good health, and had menstruated regularly for two years, up to three months from this date; after which time, without evident cause, she had been amenorrheic. She was a well-developed brunette with an abundant growth of thick black hair upon her scalp. Her past history was almost negative. So far as the surface of her body, other than the scalp was concerned, the only abnormality was the presence of a scar upon the left loin, the result of a burn received in childhood. This lesion was in perfectly normal condition; but the patient claimed that it was occasionally irritated and made sore by the pressure of the corsets that she wore.

Some three weeks before her appearance at the clinic the first lesion upon the scalp appeared, in the form of a painful little blister in the hair, near the forehead. At first pinhead sized, it gradually got larger and purulent. It finally ruptured and, when the crust that ensued came away, it carried off the hair shafts with it. So entirely painless were the later stages of the process that the patient did not know that the hair had fallen out until she accidentally discovered the red bald spot in the looking-glass. Immediately thereafter a few other small blisters appeared on the back of the scalp. They were hard and painful at first, like the primary one, so that the patient could not lay with the back of her head upon the pillow at night.

Dr. George Lesser, who referred the patient to me, first saw her at that time. There was then a red, depressed, bean-sized and tender cicatricial area near the frontal margin of the hair, and a number of very tender and indurated lesions on the back of the head, over which the hair was matted together with secretion. Treatment with various applications did not stop the progress of the affection. New nodules appeared, especially upon the vertex, all of which became suppurative, until they numbered several dozen. As it was impossible to treat the scalp effectively in the condition in which it was in, and the patient refused to have her hair cut off, she was sent to a well-known dermatologist for diagnosis and treatment. The diagnosis made was evidently pediculosis, for she was given an application to use for twenty-four hours, with the warning not to go near the fire or a light while employing it; and inquiry elicited the fact that it was the ordinary kerosene, vaselin and olive-oil application, with a little balsam of Peru, commonly employed in that affection.

This application the patient used for one day, and she claims that it burned her so terribly that she lay awake screaming with pain the whole night. Emollient applications were then ordered by the attending physician, and continued for some days with a certain amount of relief. But few nodules appeared continually upon the scalp; and as the older crusts became detached they carried away the hair entangled in them, without pain. The patient began to feel very badly; she was feverish, her sleep was disturbed, and she lost her appetite. The only way in which she could rest in bed was laying prone upon her face.

On February 21 I carefully examined her. She looked pale, depressed, and anxious. Her head was covered with an abundant growth of long, bushy, coarse black hair. Near the scalp the hair was matted firmly together and attached by dried secretion, ointment, etc. There were no traces of pediculi or their ova. Scattered all over the scalp were numerous pea to quarter-dollar-sized, reddened, slightly depressed bald spots, very tender to the touch. Between these atrophic areas the scalp was mostly hidden by the crusts; but in the few places where it was still visible it was covered with isolated minute red papules, papulo-pustules, and pustules, each of which was pierced in its center by a hair. Removal of the crusts was excessively painful; all the hair of the affected area came away with them when it was done, and a vividly red, moist depression remained behind. The entire scalp was edematous, and excessively tender to the touch. The cervical lymphatic glands were moderately swollen. She was ordered to thoroughly soak the head with a 2 per cent. solution of salicylic acid in olive-oil, and then to attempt, with soap and warm water and careful combing, to remove the crusts.

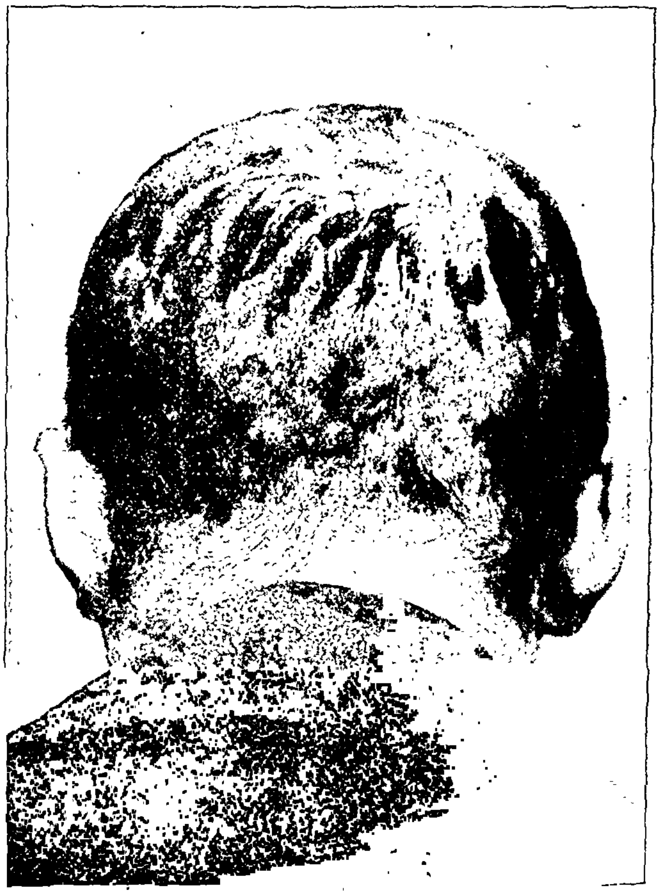

Fig. 1.—Folliculitis of scalp.

On February 23 I noted that there was but slight improvement. The patient claimed that it was impossible to remove the crusts on account of the pain. Several of the larger areas from which the crusts had fallen were swollen and edematous, and in two or three of them fairly large subcutaneous pus accumulations were found and opened.

On February 26 suppuration was progressing actively under the crusts, and a number of new and larger pus collections had to be opened. She was directed to cut off her hair close to the scalp.

On March 1 I noted that thick masses of crusts containing short hair still covered most of the scalp, the entire area of which had been or was then affected. Removal of these was still excessively painful; the surface of the scalp thereafter being as above described. Even in masses that were perfectly soft every hair came out bodily with the crusts; apparently these latter were entirely detached from the papillæ over the scalp, and it was only the removal of the crusts that caused pain. The scalp was now studded with bald areas, some of them quite large from the coalescence of smaller ones. Few new pustules had appeared recently, probably because every hair follicle had been or was affected. At this time the accompanying photograph (Fig. 1) was taken.

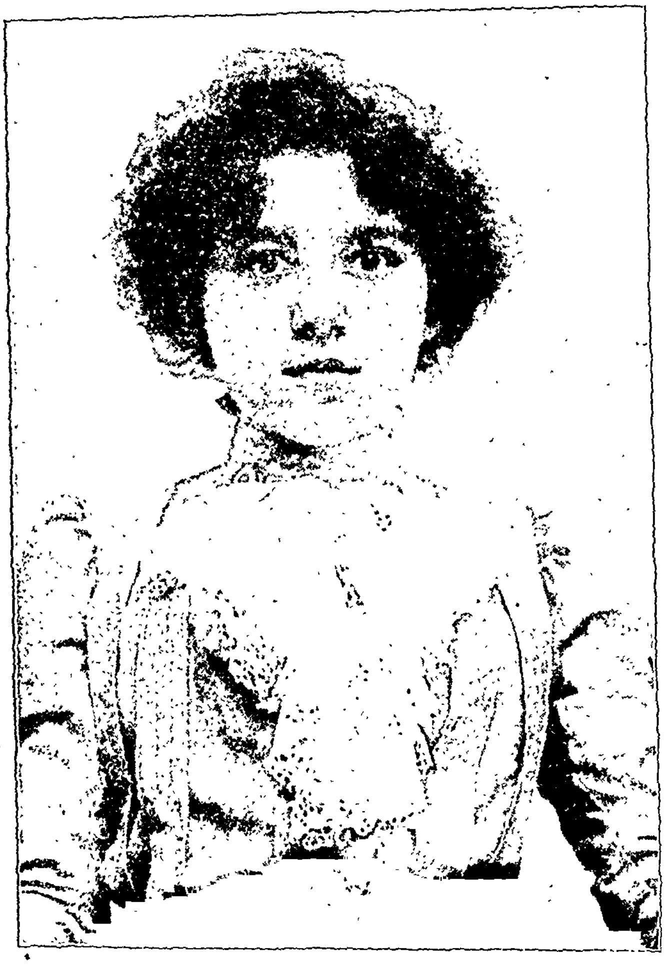

Fig. 2.—Folliculitis of scalp.

Several careful microscopic examinations of the hairs and crusts had been made during the two weeks preceding. The hair shafts were normal, not frayed, and contained no fungus. The crusts and scales consisted of masses of epithelium and fat, with detritus and bacteria, but neither mycelium nor spores. The patient refused the proposition to have the crusts removed and the scalp thoroughly cleansed under anesthesia. She was directed to continue the daily washings with soap and warm water, and to keep cloths thoroughly soaked with carron-oil continuously on the scalp.

On March 18 I noted that I had seen the patient a number of times since the last preceding record, and her condition had not improved. She looked badly, her appetite was greatly impaired, sleep was disturbed, and she was losing flesh rapidly. New pustules had occasionally appeared, pus infiltrations had to be opened and many of the older crusts had fallen off. Her scalp was apparently two-thirds denuded of hair; the bald areas were still reddened, swollen and tender, but a little less so than formerly. What hair still remained was matted down in smaller isolated bundles. Removal of crusts was a little easier, and the skin below less reddened and moist. In some of the older denuded areas a few new minute pustules were visible, not demonstrably connected with the hairs. They were beginning to whiten, and minute examination showed that fine lanugo hair was springing up over them. A few abscesses were opened, and a 3 per cent. xeroform oil applied to the scalp.

March 31 a new crop of pustules had developed over the entire occipito-cervical region, where the process had run its course, and lanugo hair was reappearing. Each papule was discrete, and pierced in its center by a hair. This gave me an excellent opportunity to study the process from the beginning. The pustles grew to small, French-pea size, and finally ruptured, extruding the hair. There was no crusting or pus collection on account of the smallness of the pilous structures and the absence of matting. The process in each case lasted about a week.

On April 14 I noted that most of the crusts were gone. No new lesions had appeared, and the older denuded areas were whitening, and covered with pale, fluffy lanugo hair. The patient claims that the xeroform oil had given her more relief than any of the other applications. For the first time in many weeks she was able to sleep in the ordinary position. She rested better, and her appetite was improving.

I saw the patient from time to time for three months thereafter. No new lesions developed. Every single one of her original hairs came out as the crusts were finally removed. The lanugo hair had increased in amount and strength, and was beginning to assume the appearance of ordinary hair.

In December, 1899, this last photograph was taken. As can be seen, there has been complete recovery. The only difference is that the new hair is a little finer and lighter than the old.

I can find no better designation for the affection than that of acute suppurative folliculitis of the scalp. I am not ready to propose an explanation of its cause. It is possible that the kerosene application had some effects upon its spread; but the folliculitis began and was quite extensive before it was employed, and the subsequent recrudescence of the disease upon the back of the head occurred entirely independently. The acuity and generalization of the process, and its superficiality, as shown by the fact that, though all the follicles were affected and all the hair detached, the papillæ were not destroyed, presents a picture differing essentially from the ordinary forms of folliculitis, and resembling only the two cases of which I have made brief mention in the early part of this paper.

Glasgow's Smallpox.—*The Lancet* of March 9 editorally considers Glasgow's smallpox predicament, for in no month has she been entirely free from the disease since its introduction there by a sailor about a year ago. Primary vaccination is well attended to, but there is absence of all official supervision and "grave reason to fear that one mark and two mark vaccination is much commoner than it ought to be." Therefore, revaccination is being advocated by the corporation and every medical man is being remunerated for all vaccinations performed on behalf of the sanitary authority. Before this was done the people did not realize the dangers and few took precautions to protect themselves. The consequent increase of smallpox was followed by an increase of vaccinations, so that now, in a population of about 700,000, about 300,000 have been recently revaccinated.

OPERATIONS FOR INJURIES TO THE MEDIAN AND ULNAR NERVES.*

B. BRINDLEY EADS, M.D.
Professor of Surgery and Clinical Surgery, Illinois Medical College.
CHICAGO.

It is my intention to discuss the subject entirely from its practical standpoint and to relate my personal experiences in dealing with the injuries of the median and ulnar nerves. These nerve trunks are most liable to be injured because of their exposed anatomic position on the arm; the most frequent result of violence applied directly to the nerve is complete division.

Functional disturbances following incised or lacerated wounds are too often overlooked and the symptoms attributed to shock. The degree of shock in such cases is not proportionate to the size of the wound or to the degree of nerve injury. The pain following the most trifling cut will often cause extreme depression. The injured person, who already is suffering pain and is in a state of nervous expectation and dread of more pain to be caused by the stitching, is thereby frequently placed in a condition of greater shock, which renders his statements relative to sensory and motor disturbances unreliable. Therefore, after direct examination of the open wound, if the least doubt exists, the necessity for a thorough operative exploration can not be overestimated.

The surgeon's duty begins with the thorough examination of every divided structure, especial attention being paid to nerves, and his duty ends only when he has proved his skill by his success, or has shown his failure to be due neither to ignorance nor negligence. The ape-hand deformity which follows wounds of the median nerve and the claw-hand deformity which follows wounds of the ulnar nerve, impress upon the surgeon his responsibility and the necessity for the most painstaking care and deliberation.

Case. 1.—The patient was a girl 9 years of age, who was brought to me in Paris, Ky., on June 15, 1891. Her general health was poor and the presence of a number of unsightly scars on the neck, with a bad family history, showed that she was a tuberculous subject. For about a month she had complained of an aching pain in the left forearm, so was disinclined to use it.

I found an enlargement the size and shape of a small hen's egg at the junction of the lower and middle thirds of the ulna. With the assistance of Dr. T. A. Roby, I made an incision at this point, evacuated a quantity of pus and, on probing, found the ulna denuded of its periosteum and roughened. I chiseled away the sclerosed shell of bone, cleaned out the entire tuberculous deposit, swabbed the cavity with Churchill's tincture of iodin, and packed the wound with iodoform gauze, that it might heal by granulation from the bottom. The wound was dressed every other day for two weeks, when I was obliged to leave Paris and, after that time, my father, Dr. D. D. Eads, dressed the wound regularly until it had entirely healed.

In January, 1892, I revisited Paris and, to my surprise, was informed that, at the time of the operation, I had divided the ulnar nerve. I found the muscles markedly degenerated and complete abolition of sensation in the territory supplied by the ulnar nerve. As I believed that the nerve had been divided, I decided to make a new operation to reunite it if possible. I accordingly made an incision three inches in length directly over the ulnar nerve and found it embedded in a mass of cicatricial tissue. The incision was now extended upward and downward for five inches and the ulnar nerve dissected from its position. As I found it had not been severed I made a new bed for it by stitching a layer of loose fascia over it.

The patient noticed improvement as soon as she awakened from the anesthesia and stated that she could now feel her little finger. She rapidly improved without any further treatment and recovered with complete restoration of function.

This case is of marked interest, because: 1. The child was too young to give an accurate account of the loss of sensation and power, which was accidentally detected by the difference in size of her hands and forearms. 2. The loss of both sensation and motion was evidently gradual and not sudden. 3. The presence of cicatricial tissue in the region of the affected nerve, whether of accidental or operative origin, is suspicious and should be considered a probable cause of loss of function in the territory supplied by that nerve. 4. Exploratory operation should be made without delay when doubt exists.

Case 2.—During my service as resident surgeon in Jefferson Medical College Hospital, in Philadelphia, in 1892, I operated on the following case of injury to the median nerve: A young man about 26 years of age had been wounded by a circular saw. He entered the accident department of the hospital, accompanied by his foreman, whose description of the accident and the amount of hemorrhage which followed caused me to order him taken to the private operating-room, where he was immediately anesthetized. On loosening the provisional tourniquet, copious arterial bleeding ensued, which was promptly arrested by digital compression of the brachial artery. After protecting the wound by several thicknesses of gauze, an Esmarch bandage was applied to the arm from the wrist well above the wound, and examination showed a lacerated wound about two inches in length extending obliquely across the inner antero-lateral aspect of the right arm about an inch and a half above the elbow. I enlarged the wound upward and downward along the course of the brachial artery, which I secured and ligated. The biceps and brachialis anticus muscles were partially divided. The divided median nerve was in plain view with the ends rather ragged. I trimmed off the ragged ends with sharp scissors, the net loss on both ends of the nerve not amounting to more than one-quarter of an inch, and placed the nerve in its natural position in the wound with the ends almost meeting. Accurate approximation was made easily and without tension.

A single transfixion stitch of fine silk was first introduced by means of a fine Hagedorn needle and tied, bringing the nerve ends together. This was reinforced by two silk sutures, one on either side, which were passed only through the sheath of the nerve.

The external wound was closed with catgut, the arm flexed and a large dressing applied. The arm was maintained in a flexed position for eight days, when it was found that the wound had united by first intention.

Paralysis resulted from the accident, with the following symptoms: Loss of pronation; impaired wrist flexion and hand-grasp with thumb extended, and anesthesia over the area supplied by the median nerve.

The first evidence of restoration of function was a return of sensation about three weeks later. Return of mobility was distinctly noticeable two months later, and when I saw the patient six months after the accident, he had acquired a fair use of the arm and expected to return to work the following week.

---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

I regard the early and favorable result of this case to be due to the clean wound, and simple division of the nerve with slight destruction of nerve tissue, which permitted accurate approximation within an hour after the accident.

Case 3.—G. H., 50 years of age, of Philadelphia, while in *Atlantic City, N. J.*, sustained an incised wound of the anterior aspect of the right forearm close to the wrist-joint. The radial and ulnar arteries, the flexor carpi radialis, flexor sublimis digitorum and palmaris longus tendons were divided. There was complete division of the median and almost complete division of the ulnar nerve. The accident was caused by the sharp blade of a knife which lay in the sand where he was sitting. On attempting to rise he pressed his wrist upon this knife blade and thus sustained the injury.

After temporary arrest of the hemorrhage, he hastened to the office of Dr. Boardman Reed. The patient was anesthetized and with the assistance of Drs. Boardman Reed and Ella Reed, I proceeded to tie the radial and ulnar arteries. I enlarged the wound upward and downward and found the divided median nerve with the ends almost approximated. I united the ends with one direct catgut suture passed through the body of the nerve. A second fine catgut suture was passed through the divided portion of the ulnar nerve. The divided tendons were found without difficulty and united with catgut.

The forearm and hand were supported in a flexed position by a suitable splint and so maintained for a period of three weeks. Wound healed by first intention.

Total paralysis and complete anesthesia resulted from the accident in the area supplied by the median nerve, but no appreciable change could be noticed in the area supplied by the partially divided ulnar nerve.

The forearm and hand were well massaged and passive motion of the fingers made to prevent them from becoming stiff.

Three weeks later the patient announced the return of sensibility in the previously insensitive area, but was much troubled because of his inability to approximate the thumb and index finger and thus hold a pen. Evidences of increasing motility rapidly followed. Ten weeks after the accident he was able to write at his desk, using his thumb and fingers with ease. He still complained of some stiffness about the wrist-joint, but expressed confidence that this would soon pass away, as it had greatly improved up to that time.

In this case there was every reason to expect speedy and complete restoration of function, as the nerve ends lay in their normal position in the wound, almost touching, thus permitting accurate approximation. In this instance I used catgut, as silk could not be obtained.

I prefer silk to any other suture material because: 1. Its permanency does not delay the union nor interfere with complete recovery. 2. Better approximation is obtained by silk. This is a most essential feature to early success, and, when tension is great, we can not dispense with it.

Relaxation by position, rest and protection by a suitable splint are conducive to successful union.

The patient was in excellent health at the time of the accident and thereafter. Massage was commenced early to overcome the likelihood of impaired mobility due to inflammatory adhesions of the joint and synovial sheaths. The arm was rubbed daily with alcohol and electricity applied.

Case 4.—J. H., a male, 34 years of age, consulted me Dec. 4, 1894, and gave the following history: On Feb. 11, 1893, while he was helping to unload a large sheet of plate glass, one of his helpers slipped on the icy pavement and, in the patient's effort to save the glass, he sustained a lacerated wound extending obliquely, from before backward along the inner side of the right arm two inches above the elbow-joint. Profuse hemorrhage followed. He was taken to the nearest surgeon—a man of good reputation—who ligated the bleeding vessel, and closed the wound, which healed promptly. At his next visit to the surgeon he complained that his hand felt numb, that he could not close it and thought that some of the "cords" had been cut.

When he consulted me, the appearance of the arm and forearm was characteristic of complete paralysis of the ulnar nerve. The muscles of the forearm supplied by the ulnar nerve were atrophied, there was marked wasting of the hypothenar eminence and hollowing of the thenar eminence. Partial flexion of the last two phalanges of the ring and little finger and extension of the first phalanges of the same fingers completed the deformity. I instructed him to grasp my index finger, which he accomplished with difficulty by first flexing the last two phalanges of all the fingers. This forced attempt caused flexion of the wrist-joint, which brought the finger more into his grasp. In the act of flexion the last two fingers did not participate as promptly as the fore and middle, and separation and approximation of the fingers could not be accomplished.

Partial anesthesia followed the division of the nerve, but sensation had returned to an appreciable extent two months after the accident, so that at the time of my examination the only area which appeared partially anesthetic was that along the ulnar side of the hypothenar eminence, and little finger.

Arrangements were made for operation at the patient's house, and, assisted by his family physician, the late Dr. Hunt, I made an incision three inches in length directly over the ulnar nerve and at right angles to the old scar, which marked the center of my incision. Upon reaching the deep fascia, I incised it on a grooved director as a guide and thus exposed the internal intermuscular septum, which was in turn divided in a similar manner bringing into view the severed interior profunda artery which, together with the triceps muscle, served as my guide in locating the ulnar nerve. I lengthened the incision in an upward direction for about two inches, found the ulnar nerve, traced it downward and found the upper bulbous end embedded in a mass of scar tissue which I carefully dissected away, exposing the nerve for nearly three inches. The distal end was also dissected from its bed of scar tissue.

Repeated sections were made of the proximal portion, with sharp scissors, before I reached healthy nerve fibrillæ, the loss amounting in all to about three-quarters of an inch. One-quarter of an inch was removed from the distal end in a similar manner. This left a decided gap from loss of substance. An attempt was then made to approximate the ends by stretching and by position of the arm, but this was unsuccessful. A flap three-quarters of an inch in length was taken from the proximal portion to bridge the gap, and was united to the distal portion by one transfixion stitch of silk reinforced by one anterior and one posterior stitch. The arm was dressed in extension and healed primarily.

A month after the operation the patient went to

Denver to live with a sister on account of his disability, and consequent inability to work, but on April 17, 1895, four months after the operation, he wrote me that he was driving a milk wagon, was able to take entire charge of a milk route, that he could close his fingers against one another, and also bring them down to the palm of his hand with considerable force. Although I have not heard from him since, I judge from this statement that in this case the operation is rapidly proving successful.

Case 5.—T. D., a boy 12 years of age, was brought to me on Sept. 18, 1897, with a lacerated wound of the right elbow-joint, caused by falling on a broken bottle. The wound extended from the outer border of the shaft of the ulna obliquely upward and inward over the posterior surface of the joint to the internal condyloid ridge one inch above the condyle.

During the delay entailed in finding the boy's father to inform him of the gravity of the accident, I obtained a clear account of the division of the ulnar nerve as manifested by its immediate effects. I asked the boy if his arm pained him, and his reply was: "No, but there is such a funny feeling all along here"—referring to the inner side of the forearm and fingers—"it feels like it's dead." Extending my index finger, I directed him to grasp it. He was unable to do so and cried out that he could never play ball again.

The patient was anesthetized and, with the assistance of Dr. J. H. Walsh, I made an examination and found the olecranon process separated from the ulna and the internal condyle from the humerus. In order to obtain a better view of the joint and its surroundings, I enlarged the wound by incisions upward and downward and dissected the superficial fascia from its deeper attachments, retracted the flap and by flexion exposed the entire elbow-joint. In order to facilitate adjustment and prevent lateral displacement, I united the olecranon process to the ulna by two silver-wire sutures and the internal condyle to the humerus by one suture of the same material. The proximal extremity of the divided nerve was found one inch above the inner condyle and the distal portion retracted for more than an inch. The ends were easily brought in good apposition by a single chromicized catgut suture passed directly through the body of the nerve, reinforced by a fine silk suture passed through the sheath on either side.

With scissors and tissue forceps I now went repeatedly over every portion of the wound most carefully, clipping the ragged tissue with its adherent foreign bodies. Sterile water was used exclusively, with the exception of hot saline solution which was employed to remove the blood clots. The complete cleanliness, perfect hemostasis and avoidance of antiseptics made me decide to close the wound with catgut sutures and without drainage. A large dressing was applied and the arm rendered immobile by a suitable splint.

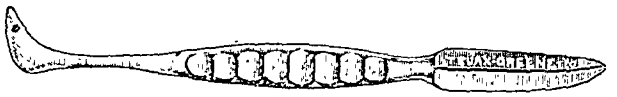
With the exception of a post-operative rise to 101 degrees on the evening of the second day, the temperature remained normal throughout. The wound was exposed on the seventh day and found to be entirely healed by first intention. The arm was retained in position for one month when, much to my surprise, the patient exhibited a fair degree of movement of the elbow-joint and of the ring and little fingers. In closing the hand he could not bring any of the finger tips in contact with the palm, but a few days later he accomplished this with ease with the exception of the little finger, which required an effort to bend to this extent. Separation and approximation of the fingers were unimpaired. More than a month after the accident a point of tenderness developed over the internal condyle and this went on to suppuration, which ceased, however, shortly after the removal of the silver wire suture.

Massage and active and passive movements were patiently continued for two months. At this time there was but slight difference in the strength of the grip in favor of the right hand.

This case teaches: 1. That next in importance to accurate apposition in case of divided nerves is the avoidance of inflammation or suppuration by cleanliness, hemostasis and irrigation with sterilized water. 2. Antisepsis must yield to asepsis when a joint is opened. 3. Buried silver-wire sutures will cause irritation even in an aseptic wound, and since this experience the writer has substituted chromicized catgut, which he considers preferable and has found sufficiently durable. 4. Immobilization in extended position lessens tension.

TECHNIQUE OF THE OPERATION.

Antisepsis can be secured only by the use of the brush, soap and water, permanganate of potash, oxalic acid and sterilized water. My unpublished experiments in the laboratory of Dr. W. M. L. Coplin, of Philadelphia, in December, 1891, proved conclusively the uselessness —from a practical standpoint—as antiseptics, of bichlorid of mercury, boric acid, carbolic acid, creolin, etc. Permanganate of potash stands alone as the ideal destroyer of germs. The skin of both operator and patient marks the line between antisepsis and asepsis.



The first and leading requisite in nerve suture is an accurate knowledge of the regional anatomy of the part. The surgeon needs every guide to render the finding of the divided nerve ends more easy. The ends may be displaced, retracted, adherent to fascia or tendons, etc., or embedded in scar tissue. When difficulty is experienced in finding the nerve at the seat of the original wound, it should be found in its known position and traced to the point of division. This procedure materially simplifies the operation and involves only a lengthening of the incision. The upper central portion of a divided nerve is enlarged, bulbous and easily found, while the lower or peripheral portion is filamentous and more difficult to discover.

A second requisite is the provision of ample operating space, and a long incision does not add appreciably to the gravity of the operation.

The Esmarch bandage should be dispensed with wherever possible, as its removal is followed by oozing which necessitates drainage, and as it prevents stretching of the nerve, thus rendering the nerve ends more liable to injury by the forceps in the hand of the operator. Slowly and precisely we proceed to find the nerve ends and free them from their imprisonment in scar tissue or their attachments to tendons and fasciæ.

The dissector—a cut of which is here given—has been invaluable to the writer in his operative work and doubtless will prove serviceable to the general surgeon. This instrument combines the advantages of a director, dissector and scalpel handle. It is made from a single piece of metal, 6½ inches in length, consisting of a central portion, the handle and two extremities, one of which is hook-shaped and fenestrated near the end, and the other, slightly curved and blade-shaped, has

a single longitudinal groove in the center. The latter is used for the isolation of structures located in tissue which can be pushed aside, thus avoiding hemorrhage and keeping the field of operation dry. This is especially valuable in breaking down adhesions and in the exposure of important vessels and nerves. The single groove serves as a guide for the back of the knife in making the incision, and takes the place of the grooved director. Therefore this extremity may be regarded as a combined grooved director and separator of tissues. When greater force is required in dissection, the hook-shaped extremity is brought into use. The eye acts as a ligature carrier; the blunt extremity of the hook, which can not be forced through the wall of the blood-vessel, makes it a convenient aneurysm needle.

The nerve ends are freshened ready for accurate approximation, which is assisted by position and, if necessary, by stretching of the nerve trunk. An ordinary cambric needle carrying a single, direct suture of chromicized catgut is passed through the nerve on each side, from one-eighth to one-quarter of an inch from its extremities, and tied, but not too tightly, as accurate approximation is easily defeated by displacement due to overlapping. Two or more fine silk sutures are now passed through the sheath of the nerve, to more accurately complete the approximation and to increase the strength of the union. In tying these sutures, great care must be taken to prevent the sheath from being folded in between the nerve ends. If, after approximation, there is too great tension and consequent liability of the sutures to cut out, I would recommend that a relaxation suture of chromicized catgut be passed in an antero-posterior direction through the substance of the nerve above the first suture.

Restoration of function is often delayed and this delay is proportionate to the degree of degeneration of the peripheral end, the consequent atrophy of muscle and fixity of joints. These very symptoms, however, may result from a widespread septic *inflammation* complicating the original wound and causing inflammatory adhesions of joints and tendons with resulting impairment of mobility. (Rose.)

In the hands of the most careful operator some cases will result in total failure. Fortunately, however, the splendid results in recent years have aroused medical men and dispelled all doubt as to the necessity of the measure. I have obtained from the literature reports of 294 cases, with the following results:

	Successful.	Improved.	Failure.	Total.
Primary suture	40.52% 62	40 52% 62	18.95% 29	153
Secondary suture	43.26% 61	43.26% 61	13.38% 19	141
Total	41.83% 123	41.83% 123	16.33% 48	294

From my own experience, therefore, fortified by the observations of others, I believe we are justified in saying to our patients that, while positive results can not be promised, the great majority of operations are followed by cure, and that in the majority of the remainder improvement takes place after operation. Without operation the tendency is always to grow worse. This is an assurance of hope to the sufferer, and yet its correctness is borne out by our experience.

CONCLUSIONS.

1. Provision of ample operating space is the first requisite to success.

2. Suppuration is inimical to success and can be prevented by cleanliness, hemostasis and avoidance of chemical irritants and drainage-tubes.

3. Chromicized catgut and fine silk furnish the best suture material. The single transfixion stitch should be of catgut and the two or more perineurotic stitches, of fine silk.

4. Tension may be overcome by position and loss of substance by nerve stretching and bridging by the flap method.

5. Immediate suture of clean nerve ends accurately approximated is conducive to early functional restoration.

6. Relaxation by position, rest and protection by suitable splint are conducive to successful union.

7. Cicatricial compression may be anticipated and the nerve placed out of harm's way.

8. Asepsis in primary, and antisepsis and asepsis in secondary nerve suture should be the practice of to-day. Antiseptics have an irritative and destructive effect

beneath the integument, cause inflammation and render drainage necessary.

PATHOLOGICAL CONDITIONS FOUND IN MEAT INSPECTION.*

D. E. SALMON, D.V.M.
WASHINGTON, D. C.

The more common and important pathological conditions found in meat inspection are no doubt subjects of considerable interest to the members of this Association. These conditions may affect the public health to a certain extent, and they are unquestionably worthy of careful study by the sanitarian as well as the pathologist.

The federal meat-inspection service having been in operation about nine years, has now reached a stage of development and an approach to uniformity of procedure which justifies the expectation that some thought may hereafter be given to the utilization for scientific purposes of its records and of some of the material which is found. While we have not in the past entirely neglected the collection and study of the pathological material, the imperative necessity of organization and of the investigation and control of the more destructive animal plagues has prevented us from using this material to any great extent either for illustrative purposes or for scientific study.

The specimens which are exhibited here are nearly all in a fresh condition and have been preserved by freezing. They are only such as could be collected in a comparatively short time, but they are of special value as showing the natural appearance of the affected meat. To give some idea of the frequency or infrequency of disease in our meat-producing animals, I have taken from our reports some statistics covering the two fiscal years beginning July 1, 1897, and ending June 30, 1899. These statistics are especially valuable on account of the large number of carcasses inspected during that period, and refer entirely to the post-mortem examination.

During the two years mentioned, the number of cattle examined reached a total of 8,831,927. Of these cattle 19,454 entire carcasses and parts of 23,106 additional carcasses were condemned. This means that 22 carcasses in 10,000 were entirely condemned, and that 26 carcasses in 10,000 were partly condemned, making a total of 48 carcasses in 10,000 condemned in whole or in part. Of the 23,106 carcasses parts of which were condemned, 12,641 were affected by bruises or injuries; 7,120 by abscesses; 3,025 by localized actinomycosis; 268 by localized tuberculosis; 11 by tumors; 6 by hydatids and the remainder by circumscribed inflammation of various organs. Of the 19,454 carcasses which were wholly condemned 7015 were affected with tuberculosis; 5172 by actinomycosis; 2530 by anemia, emaciation, etc.; 2227 by bruises and injuries; 598 by septicemia; 384 by pneumonia; 268 by peritonitis; 222 by pyemia; 212 by icterus; 205 by abscesses; 166 by Texas fever; 95 by advanced pregnancy; 90 by enteritis; 44 by cancer; 42 by gangrene; 24 by metritis; 15 by recent parturition; 1 by anthrax, and the remainder—144—mostly by tumors and inflammations of the various organs.

The number of sheep inspected during this period reached 11,110,776. Of these sheep, 8394 carcasses, or 7.5 per 10,000 were wholly condemned and 650 carcasses, or 0.6 per 10,000, were condemned in part. Taking the carcasses of which only parts were condemned and 379, or more than one-half, were affected by bruises and injuries; 132 by abscesses; 91 by hydatids, 41 by the esophagostoma columbianum, the parasite causing the nodular disease of the intestines, 4 by scabies and 3 by tuberculosis. Of the 8394 entire carcasses of mutton condemned, 2345 were affected with anemia and emaciation; 1696 by bruises and injuries; 667 by tuberculosis and pseudo-tuberculosis; 550 by abscesses; 464 by pneumonia; 422 by uremia; 371 by septicemia; 370 by icterus; 256 by pyemia; 204 by pleurisy; 171 by ascites; 154 by scabies; 131 by advanced pregnancy; 118 by hydatids—echinococcus—and the remainder—375—mostly by inflammation of various organs, fever, recent parturition, parasites, tumors and cancer.

The number of hogs slaughtered under inspection during the same period was 44,841,779. Of these hogs 106,555 carcasses were wholly condemned, being about 24 per 10,000, and 58,491, or 13 per 10,000, were condemned in part. Of the carcasses only partially condemned 37,167 were affected by bruises or injuries; 7853 by tumors; 7338 by abscesses; 1971 by hydatids; 1683 by tuberculosis; 1313 by mammitis; 1119 by pleurisy and 47 by actinomycosis. Of the carcasses wholly condemned 85,904 were affected by hog cholera and swine plague; 4021 by tuberculosis; 2298 by icterus; 2065 by pyemia; 1847 by abscesses; 1709 by pneumonia; 1570 by advanced pregnancy; 1463 by septicemia; 1294 by bruises and injuries; 1099 by tumors; 1500 by inflammation of organs in the abdominal cavity; 536 by anemia and emaciation; 321 by recent parturition; 267 by fever; 113 by scabies; 43 by actinomycosis; 60 by cysticercus cellulosæ or measles of swine; 23 by hydatids; 9 by cancer. The remaining 313 were for the most part affected by skin diseases, gangrene and inflammation of various organs. There has not been included in this statement the condemnations for trichinæ infestation, since pork for the domestic markets is not examined microscopically.

---

*Presented to the Section on Pathology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The proportion of condemnations for the different varieties of animals per 10,000 slaughtered is shown by the following table:

	Cattle.	Sheep.	Swine.
Whole carcasses, per 10,000........	22	7.5	24
Parts of carcasses, per 10,000......	26	0.6	13
	—	—	—
Total	48	8.1	37

In general terms it may be said that the proportion of condemnations with cattle and swine correspond quite closely, while with sheep it drops almost to one-fifth of the figures for swine and one-sixth of those for cattle. The relatively large number of condemnations with cattle is somewhat surprising since they are generally considered the most hardy and healthy of our domesticated animals. An examination of the causes of condemnation shows, however, that more than half of the parts of carcasses rejected were affected by injuries received in shipment, while almost one-third were condemned for abscesses, many of which no doubt were also due to mechanical injuries. That is, cattle, on account of their size, weight and combative disposition are particularly liable to injuries which may require the removal of a part of the carcass. Making allowance for such injuries, the condemnations with cattle will be no greater than with swine. The small proportion of condemnations with sheep is remarkable, particularly when we consider the delicacy of their constitution and their feeble powers of resistance to unfavorable conditions.

When we examine into the causes of condemnations with cattle we are impressed by the relative number due to actinomycosis and tuberculosis. Of the whole carcasses condemned, 26 per cent. were affected with actinomycosis and 36 per cent. with tuberculosis. Of the parts of carcasses condemned, 13 per cent. were affected with actinomycosis and 1 per cent. with tuberculosis. Nevertheless, there is a surprisingly small proportion of the beef-producing cattle, as they come to our large abattoirs, which are affected with these diseases. Taking the total condemnations of whole carcasses and parts of carcasses for tuberculosis, we find but 8.1 per 10,000 animals; and in the same manner, with actinomycosis we find 9.2 per 10,000 animals. Actinomycosis, also, affects hogs and sheep, but much more rarely than cattle. Thus with hogs, 43 whole carcasses and 47 parts of carcasses were condemned for this disease out of 44,841,779 carcasses inspected; that is something over two affected carcasses to a million. This does not give an accurate idea of the frequency of actinomycosis with hogs, however, as many of the tumors for which condemnations were made were undoubtedly actinomycotic growths. In sheep two whole carcasses were condemned for actinomycosis out of 11,110,776. Tuberculosis is one of the principal diseases found in swine, though it is far less common than with cattle. Adding together the number of whole carcasses and parts of carcasses condemned we find that approximately 1.3 hogs per 10,000 are affected. Tuberculosis in sheep is a very rare disease. Our reports give tuberculosis and pseudo-tuberculosis together, the latter being much the more common. Including both, however, there are specified but 6 per 100,000 sheep inspected. It is quite probable that some of the abscesses reported were due to pseudo-tuberculosis.

Tuberculosis in cattle is generally a localized disease. It affects most frequently the bronchial and mediastinal lymph-glands and lungs, but very often the abdominal lymph-glands, liver or spleen are invaded. Sometimes it is generalized and tubercles are found widely distributed, affecting even the muscles and bones. Some statistics show the uterus involved in about 10 per cent. of the tuberculous cows and the udder in 1 or 2 per cent.

Our inspectors are instructed to condemn: 1, all carcasses affected with generalized tuberculosis; 2, all carcasses with extensive localized tuberculosis, and 3, all carcasses with localized tuberculosis that show signs of emaciation. This ruling is considerably more stringent than the European practice, which allows carcasses affected with localized tuberculosis to go on the market without regard to the extent of the lesions, except in case of marked emaciation. Even generalized tuberculosis is not always considered, in other countries, a sufficient cause for condemnation, and those carcasses in which the lesions are apparently confined to the organs of the body cavities, especially if the process of generalization has not been recent, are passed as fit for food.

The beef cattle which come to our large abattoirs are singularly free from tuberculosis, since only one animal in 1500 or 2000 is affected to an extent which causes the condemnation of any part of the carcass. Dairy cattle, however, are much more seriously affected, and from 5 to 10 per cent. may be found tuberculous. In European countries the tuberculosis of cattle is much more frequent than in the United States, the slaughterhouse statistics showing from 20 to 50 per cent. of all such animals to be affected.

There is a possibility of fetal infection in bovine tuberculosis, but such cases are quite rare. The congenital form of tuberculosis exists in probably less than 1 per cent. of the calves born of tuberculous mothers. The tuberculosis of calves arises from virulent milk used as food rather than from infection in utero. The specimens of tuberculous udders illustrate the appearance of the affected gland, and also the possibility of large quantities of virulent material finding its way into the milk. The milk should be considered dangerous in all cases in which the disease has invaded the udder, and it may also be infectious in advanced cases of tuberculosis although no lesions can be discovered in the udder.

There is not time on this occasion to discuss the transmission of bovine tuberculosis to man. I believe that such transmission occurs and that precautions should be taken to guard against it. The frequency with which tuberculosis is communicated from animals to man can only be determined by the long-continued, careful and concerted observation of physicians. The data which we now have is meager and much of it is unsatisfactory. It consists of accidental inoculations and of primary tuberculosis of the intestines or mesenteric glands. In the former case the origin of the lesion is generally very clear; in the latter we can only infer that the bacilli were introduced with the food. When the death of a number of persons in the same institution —school, asylum—occurs from abdominal tuberculosis and the cows furnishing the milk are found to have their udders affected with the disease, and to be producing virulent milk, the evidence of transmission is about as strong as we can expect to obtain. Unfortunately, sufficient attention has not been given to such observations in this or in other countries, so far as I am aware. Careful post-mortem examinations of children which die in asylums and hospitals should in time furnish most valuable evidence.

As an example of what the speaker has in mind, he would refer to an article by Dr. George F. Still, M.A., M.D., M.R.C.P.[1] This communication gives the results of 769 consecutive autopsies on children, all being hospital patients. Of these, 269 presented lesions of tuberculosis. As far as could be ascertained, 53 were infected by way of the intestine, and 10 others were probably infected through this channel. That is, 63 out of 269, or 23.4 per cent., probably contracted the disease by infection taken with the food. There were 43 cases in which death occurred from some other cause than tuberculosis; and these cases were noted as furnishing almost indisputable evidence of the method of infection in each individual case, since the tuberculous disease had either been arrested in its early stages or had not yet progressed beyond the initial stage. With these cases the evidence as to primary focus of infection was as follows: Lung, 26; intestine, 16; ear, 1. That is, where the evidence was most clear, the infection was by the digestive tract in 37.2 per cent. of the cases. It is a pity that we have not enough evidence of this character from the principal countries to enable us to form an intelligent opinion as to the relation, if any, which exists between the frequency of tuberculosis in the food-producing animals, and that of abdominal tuberculosis in mankind.

Although tuberculosis is less common in swine than in cattle it has a greater tendency to generalization and affected carcasses need to be very carefully scrutinized before they are passed as fit for food.

The specimens showing the tuberculous lesions in cattle and hogs will be found most interesting, particularly those from the udder of the cow and those illustrating the generalized form of the disease in swine.

The pseudo-tuberculosis of sheep is a very interesting disease, generally found among animals which have originated in the southwestern section of the United States, from Texas to California inclusive. It is generally observed in mature animals, though it is occasionally found in lambs. The lymphatic glands, lungs and liver are the parts oftenest affected. One or more of the prescapular, inguinal, sublumbar, mediastinal or bronchial glands may be found enlarged and on pressure gives a sensation such as would be expected from a thick-walled sac containing semi-fluid material. On section the contents are found to be yellowish green and caseous, while the capsule is grayish-white, fibrous and firm. Sometimes the caseous substance closely resembles the contents of softened tubercles, but in older lesions it has a greater consistency, finally becoming dry and mealy. As a rule, these lesions do not present evidence of calcification. The lesions in the lungs, liver and other organs have a similar appearance. They are well defined and surrounded by a wall of fibrous tissue.

Microscopic examination of cover-glass preparations made from the caseous material and stained by Gram's method demonstrates the presence of a small, ovoid bacillus. It develops on agar in the course of forty-eight hours as an irregular, whitish colony, with crenated border and papillated center. In bouillon turbidity occurs in thirty-six hours and in forty-eight hours a heavy, white granular precipitate forms at the bottom of the tube.

Intravenous inoculations of rabbits and guinea-pigs cause death in six to ten days with cheesy foci of varying size in the lungs, liver and spleen. Subcutaneous inoculations cause death in these animals in twenty-five to thirty days, with caseous degeneration of the tissues near the point of inoculation and lesions of the neighboring lymphatics. Feeding experiments with these small animals produce fatal results in eight to ten weeks, the lesions being identical with those caused by intravenous inoculation, except that the lymphatic glands of the head and throat are more frequently involved. Feeding experiments with sheep have given negative results. Intravenous inoculation of sheep with material from the caseous lymphatic glands of diseased animals have produced in the course of eight weeks only small caseous foci, the size of a hazelnut, in the lungs.

Another interesting disease, of which specimens are shown, is the nodular disease of the sheep's intestine. These nodules, which have often been regarded as of tubercular nature, are really due to the irritation caused by the immature form of an intestinal worm—the esophagostoma columbianum. This is a very common disease and apparently only affects the sheep's health when the nodules are so numerous as to interfere with the assimilation of the food. In some parts of the country the esophagostoma is a great pest and multiplies so rapidly that it is practically impossible to keep sheep successfully in large flocks.

The frequency with which hogs are found affected with cholera and swine plague is indicated by the fact that of 106,555 carcasses condemned, 85,904, or 80.7 per cent., were rejected for this cause. It is therefore important that inspectors should be familiar with the appearances of meat affected with this disease.

Your attention is invited to the lesions of actinomycosis in the jaw, tongue, liver, lungs and udder. The actinomycotic process is most frequently seen in this country affecting the maxillary bones, where it causes a large, hard suppurating tumor which disfigures the animal and gives it a very unprepossessing appearance. The tongue is often affected, becoming enlarged, hard and filled with nodules containing caseous material. Actinomycotic tumors may be found in the pharynx, larynx and esophagus. Lesions resembling those of tuberculosis are found in the lungs, liver and peritoneum. In general, it may be said that the actinomycotic lesion develops either with a tubercular appearance, or as a soft, moist, reddish tumor, or, finally, as a hard fibrous tumor. There is a tendency to disintegration and suppuration and sometimes the lesion consists simply of an abscess. The presence of the actinomyces tufts constitutes a reliable means of diagnosis.

The repulsive appearance of animals affected with actinomycosis of the head has inclined some sanitarians to give undue attention to this disease to the neglect of others having a greater effect on the flesh and that are more dangerous to the consumer. As this disease is probably not transmitted from animals to man the car-

and swine plague; 4021 by tuberculosis; 2298 by icterus; 2065 by pyemia; 1847 by abscesses; 1709 by pneumonia; 1570 by advanced pregnancy; 1463 by septicemia; 1294 by bruises and injuries; 1099 by tumors; 1500 by inflammation of organs in the abdominal cavity; 536 by anemia and emaciation; 321 by recent parturition; 267 by fever; 113 by scabies; 43 by actinomycosis; 60 by cysticercus cellulosæ or measles of swine; 23 by hydatids; 9 by cancer. The remaining 313 were for the most part affected by skin diseases, gangrene and inflammation of various organs. There has not been included in this statement the condemnations for trichinæ infestation, since pork for the domestic markets is not examined microscopically.

The proportion of condemnations for the different varieties of animals per 10,000 slaughtered is shown by the following table:

	Cattle.	Sheep.	Swine.
Whole carcasses, per 10,000........	22	7.5	24
Parts of carcasses, per 10,000......	26	0.6	13
Total	48	8.1	37

In general terms it may be said that the proportion of condemnations with cattle and swine correspond quite closely, while with sheep it drops almost to one-fifth of the figures for swine and one-sixth of those for cattle. The relatively large number of condemnations with cattle is somewhat surprising since they are generally considered the most hardy and healthy of our domesticated animals. An examination of the causes of condemnation shows, however, that more than half of the parts of carcasses rejected were affected by injuries received in shipment, while almost one-third were condemned for abscesses, many of which no doubt were also due to mechanical injuries. That is, cattle, on account of their size, weight and combative disposition are particularly liable to injuries which may require the removal of a part of the carcass. Making allowance for such injuries, the condemnations with cattle will be no greater than with swine. The small proportion of condemnations with sheep is remarkable, particularly when we consider the delicacy of their constitution and their feeble powers of resistance to unfavorable conditions.

When we examine into the causes of condemnations with cattle we are impressed by the relative number due to actinomycosis and tuberculosis. Of the whole carcasses condemned, 26 per cent. were affected with actinomycosis and 36 per cent. with tuberculosis. Of the parts of carcasses condemned, 13 per cent. were affected with actinomycosis and 1 per cent. with tuberculosis. Nevertheless, there is a surprisingly small proportion of the beef-producing cattle, as they come to our large abattoirs, which are affected with these diseases. Taking the total condemnations of whole carcasses and parts of carcasses for tuberculosis, we find but 8.1 per 10,000 animals; and in the same manner, with actinomycosis we find 9.2 per 10,000 animals. Actinomycosis, also, affects hogs and sheep, but much more rarely than cattle. Thus with hogs, 43 whole carcasses and 47 parts of carcasses were condemned for this disease out of 44,841,779 carcasses inspected; that is something over two affected carcasses to a million. This does not give an accurate idea of the frequency of actinomycosis with hogs, however, as many of the tumors for which condemnations were made were undoubtedly actinomycotic growths. In sheep two whole carcasses were condemned for actinomycosis out of 11,110,776. Tuberculosis is one of the principal diseases found in swine, though it is far less common than with cattle. Adding together the number of whole carcasses and parts of carcasses condemned we find that approximately 1.3 hogs per 10,000 are affected. Tuberculosis in sheep is a very rare disease. Our reports give tuberculosis and pseudo-tuberculosis together, the latter being much the more common. Including both, however, there are specified but 6 per 100,000 sheep inspected. It is quite probable that some of the abscesses reported were due to pseudo-tuberculosis.

Tuberculosis in cattle is generally a localized disease. It affects most frequently the bronchial and mediastinal lymph-glands and lungs, but very often the abdominal lymph-glands, liver or spleen are invaded. Sometimes it is generalized and tubercles are found widely distributed, affecting even the muscles and bones. Some statistics show the uterus involved in about 10 per cent. of the tuberculous cows and the udder in 1 or 2 per cent.

Our inspectors are instructed to condemn: 1, all carcasses affected with generalized tuberculosis; 2, all carcasses with extensive localized tuberculosis, and 3, all carcasses with localized tuberculosis that show signs of emaciation. This ruling is considerably more stringent than the European practice, which allows carcasses affected with localized tuberculosis to go on the market without regard to the extent of the lesions, except in case of marked emaciation. Even generalized tuberculosis is not always considered, in other countries, a sufficient cause for condemnation, and those carcasses in which the lesions are apparently confined to the organs of the body cavities, especially if the process of generalization has not been recent, are passed as fit for food.

The beef cattle which come to our large abattoirs are singularly free from tuberculosis, since only one animal in 1500 or 2000 is affected to an extent which causes the condemnation of any part of the carcass. Dairy cattle, however, are much more seriously affected, and from 5 to 10 per cent. may be found tuberculous. In European countries the tuberculosis of cattle is much more frequent than in the United States, the slaughterhouse statistics showing from 20 to 50 per cent. of all such animals to be affected.

There is a possibility of fetal infection in bovine tuberculosis, but such cases are quite rare. The congenital form of tuberculosis exists in probably less than 1 per cent. of the calves born of tuberculous mothers. The tuberculosis of calves arises from virulent milk used as food rather than from infection in utero. The specimens of tuberculous udders illustrate the appearance of the affected gland, and also the possibility of large quantities of virulent material finding its way into the milk. The milk should be considered dangerous in all cases in which the disease has invaded the udder, and it may also be infectious in advanced cases of tuberculosis although no lesions can be discovered in the udder.

There is not time on this occasion to discuss the transmission of bovine tuberculosis to man. I believe that such transmission occurs and that precautions should be taken to guard against it. The frequency with which tuberculosis is communicated from animals to man can only be determined by the long-continued, careful and concerted observation of physicians. The data which we now have is meager and much of it is unsatisfactory. It consists of accidental inoculations and of primary tuberculosis of the intestines or mesenteric glands. In the former case the origin of the lesion is generally very clear; in the latter we can only infer that the bacilli were introduced with the food. When the death of a number of persons in the same institution —school, asylum—occurs from abdominal tuberculosis and the cows furnishing the milk are found to have their udders affected with the disease, and to be producing virulent milk, the evidence of transmission is about as strong as we can expect to obtain. Unfortunately, sufficient attention has not been given to such observations in this or in other countries, so far as I am aware. Careful post-mortem examinations of children which die in asylums and hospitals should in time furnish most valuable evidence.

As an example of what the speaker has in mind, he would refer to an article by Dr. George F. Still, M.A., M.D., M.R.C.P.[1] This communication gives the results of 769 consecutive autopsies on children, all being hospital patients. Of these, 269 presented lesions of tuberculosis. As far as could be ascertained, 53 were infected by way of the intestine, and 10 others were probably infected through this channel. That is, 63 out of 269, or 23.4 per cent., probably contracted the disease by infection taken with the food. There were 43 cases in which death occurred from some other cause than tuberculosis; and these cases were noted as furnishing almost indisputable evidence of the method of infection in each individual case, since the tuberculous disease had either been arrested in its early stages or had not yet progressed beyond the initial stage. With these cases the evidence as to primary focus of infection was as follows: Lung, 26; intestine, 16; ear, 1. That is, where the evidence was most clear, the infection was by the digestive tract in 37.2 per cent. of the cases. It is a pity that we have not enough evidence of this character from the principal countries to enable us to form an intelligent opinion as to the relation, if any, which exists between the frequency of tuberculosis in the food-producing animals, and that of abdominal tuberculosis in mankind.

Although tuberculosis is less common in swine than in cattle it has a greater tendency to generalization and affected carcasses need to be very carefully scrutinized before they are passed as fit for food.

The specimens showing the tuberculous lesions in cattle and hogs will be found most interesting, particularly those from the udder of the cow and those illustrating the generalized form of the disease in swine.

The pseudo-tuberculosis of sheep is a very interesting disease, generally found among animals which have originated in the southwestern section of the United States, from Texas to California inclusive. It is generally observed in mature animals, though it is occasionally found in lambs. The lymphatic glands, lungs and liver are the parts oftenest affected. One or more of the prescapular, inguinal, sublumbar, mediastinal or bronchial glands may be found enlarged and on pressure gives a sensation such as would be expected from a thick-walled sac containing semi-fluid material. On section the contents are found to be yellowish green and caseous, while the capsule is grayish-white, fibrous and firm. Sometimes the caseous substance closely resembles the contents of softened tubercles, but in older lesions it has a greater consistency, finally becoming dry and mealy. As a rule, these lesions do not present evidence of calcification. The lesions in the lungs, liver and other organs have a similar appearance. They are well defined and surrounded by a wall of fibrous tissue.

Microscopic examination of cover-glass preparations made from the caseous material and stained by Gram's method demonstrates the presence of a small, ovoid bacillus. It develops on agar in the course of forty-eight hours as an irregular, whitish colony, with crenated border and papillated center. In bouillon turbidity occurs in thirty-six hours and in forty-eight hours a heavy, white granular precipitate forms at the bottom of the tube.

Intravenous inoculations of rabbits and guinea-pigs cause death in six to ten days with cheesy foci of varying size in the lungs, liver and spleen. Subcutaneous inoculations cause death in these animals in twenty-five to thirty days, with caseous degeneration of the tissues near the point of inoculation and lesions of the neighboring lymphatics. Feeding experiments with these small animals produce fatal results in eight to ten weeks, the lesions being identical with those caused by intravenous inoculation, except that the lymphatic glands of the head and throat are more frequently involved. Feeding experiments with sheep have given negative results. Intravenous inoculation of sheep with material from the caseous lymphatic glands of diseased animals have produced in the course of eight weeks only small caseous foci, the size of a hazelnut, in the lungs.

Another interesting disease, of which specimens are shown, is the nodular disease of the sheep's intestine. These nodules, which have often been regarded as of tubercular nature, are really due to the irritation caused by the immature form of an intestinal worm—the esophagostoma columbianum. This is a very common disease and apparently only affects the sheep's health when the nodules are so numerous as to interfere with the assimilation of the food. In some parts of the country the esophagostoma is a great pest and multiplies so rapidly that it is practically impossible to keep sheep successfully in large flocks.

The frequency with which hogs are found affected with cholera and swine plague is indicated by the fact that of 106,555 carcasses condemned, 85,904, or 80.7 per cent., were rejected for this cause. It is therefore important that inspectors should be familiar with the appearances of meat affected with this disease.

Your attention is invited to the lesions of actinomycosis in the jaw, tongue, liver, lungs and udder. The actinomycotic process is most frequently seen in this country affecting the maxillary bones, where it causes a large, hard suppurating tumor which disfigures the animal and gives it a very unprepossessing appearance. The tongue is often affected, becoming enlarged, hard and filled with nodules containing caseous material. Actinomycotic tumors may be found in the pharynx, larynx and esophagus. Lesions resembling those of tuberculosis are found in the lungs, liver and peritoneum. In general, it may be said that the actinomycotic lesion develops either with a tubercular appearance, or as a soft, moist, reddish tumor, or, finally, as a hard fibrous tumor. There is a tendency to disintegration and suppuration and sometimes the lesion consists simply of an abscess. The presence of the actinomyces tufts constitutes a reliable means of diagnosis.

The repulsive appearance of animals affected with actinomycosis of the head has inclined some sanitarians to give undue attention to this disease to the neglect of others having a greater effect on the flesh and that are more dangerous to the consumer. As this disease is probably not transmitted from animals to man the carcasses are only condemned when there is emaciation or when the lesions are so large, active or disseminated as to affect the system at large.

---

[1] British Med. Jour., Aug. 19, 1899, p. 455.

Perhaps I should explain, that while in some countries, possibly in most countries, the meat inspectors condemn only such meat as they believe to be clearly injurious to consumers, we go somewhat farther in this country and condemn much meat which is not actually injurious, but which for various reasons is repugnant. In this class may be placed the carcasses of animals advanced in pregnancy, or those which have recently given birth to their young; the unborn fetus and the very young calf or lamb; the carcasses of animals suffering from pneumonia, pleurisy or some other non-infectious disease; the greater part of the actinomycotic carcasses and of those affected with extensive though localized tuberculosis. On the same principle we destroyed the carcasses of all cattle affected with contagious pleuropneumonia when we were engaged in the work of eradicating that disease, although it had been proved by European experience that the flesh of these animals might be consumed with impunity.

Turning now to the animal parasites which are encountered on the slaughtering floor, it may be observed that the subject of meat inspection for these organisms bears both a direct and an indirect relation to public health, for we find parasites, some of which are transmissible directly to man through the meat eaten as food, while others are transmissible indirectly, first passing a stage of their life in some other host. Among those which are transmissible directly to man, your attention is especially invited to the larval stages of tape-worms. Cystericus bovis occurs in cattle and when eaten by man gives rise to the common tapeworm found in this country, tænia saginata by name. The specimen exhibited is a cross-section through the tongue of a calf, and these bladder-like structures more or less resembling particles of fat represent the larval worm. This particular tape-worm is not an especially dangerous parasite. It may bring about digestive troubles, and it is occasionally very difficult to expel it, but, as a rule, we may say that the parasite is only of temporary importance, its effects passing off when the worm is expelled. With this specimen, the matter is entirely different. This is the so-called "measle tape-worm," tænia solium, and is contracted by swallowing the larval bladder worm, cystericus cellulosæ by name, which occurs in pork. Owing to the fact that Americans are in the habit of cooking or curing pork quite thoroughly before consuming it, the larval stage is usually killed, hence the adult parasite tænia solium in man is rather infrequent in this country. It will, however, be found among Germans and others who are in the habit of eating raw or rare pork. Sometimes, perhaps, physicians do not attempt to distinguish between cases of infection among their patients by the two worms just mentioned. The fact should not be lost sight of, however, that the tænia solium is a very much more dangerous parasite than tænia saginata, for if a patient soils his hands with the microscopic eggs during defecation or if he has reverse peristalsis of the intestine strong enough to carry one or more segments of the tape-worm into the stomach, he infects himself with the larval stage. In this case the embryos escape from the segments into the stomach and wander to various parts of the body, more especially to the muscles, the eyes and the brain. If one of the larvæ develops in the eye, more or less serious conditions may result, while if they develop in the brain, they may lead to serious complications, according to the part of the brain in which they grow, and may finally result in death. Again, it may not be amiss to remind physicians that, in treating for tape-worms, they constantly stand in danger of infecting themselves with the larval stage, if they handle the tænia solium, a danger which does not exist in connection with tænia saginata. The existence of these two parasites in our American cattle and hogs, leads me to suggest that the practicing physician has a duty to perform in seeing that all tape-worms passed by his patients, are totally destroyed, unless preserved for scientific work. It too often happens that the patient is not properly instructed in this matter and passes the worm in some place where the eggs are scattered so that they afterward infect cattle and hogs.

The meat inspection in Germany has resulted in decreasing the frequency of tape-worm disease in man, as well as the infection with the larval stage of cysticercus cellulosæ. We have no exact statistics on this subject for the United States, but it would appear that the federal meat inspection system must necessarily contribute its share to the decrease of tape-worm disease. If physicians will do their part in burning the tape-worms passed by their patients, there is no reason why we should not gradually eradicate these two parasites from the country.

Another parasite transmissible directly to man by means of the meat, is the well-known trichina spiralis, the cause of the disease trichinosis. Fortunately, our curing and culinary methods are a great protection against infection with this worm. We do not make an inspection with a view of excluding this parasite from the pork which is consumed in this country. It would cost us nearly three million dollars per annum to accomplish this, and the statistics of Germany show beyond a question that a microscopic examination is not of such great value as is generally supposed. The Bureau of Animal Industry has recently compiled over fourteen thousand cases of trichinosis in Germany from 1860 till 1898, inclusive, and from our compilation it results that the general mortality of the disease is 5.6 per cent. Of over six thousand cases which occurred during the years 1881 till 1898, inclusive, about 51 per cent. of all the cases were due to faults in the microscopic inspection, the vast majority of these occurring from meat which had been inspected and passed as free from trichinæ. One is scarcely warranted in recommending that this Government expend three million dollars per annum for the general introduction of a sanitary inspection which the German statistics prove to be so uncertain, an inspection which is calculated to raise a false sense of security among our people, and which might tend to increase the dangerous custom of eating raw or rare pork. Trichinosis may be prevented much more effectually by educating the public to the use of thoroughly cured pork and to the idea that when it is not thoroughly cured, it should, at least, be thoroughly cooked.

Finally, I invite your special attention to an animal parasite which is apparently on the increase in this country. I refer to the echinococcus, the cause of the hydatid disease. This bladder-worm may be found in almost any part of the body of the meat-producing animals, and especially in the lungs and liver of cattle, sheep and swine. You will pardon me, I trust, for recalling some points in its life history which are no doubt familiar to you. If a man were to eat an affected organ, it would do him no harm, for the parasite is not directly transmissible from these animals to man. If, however. the hydatid worm is fed to a dog, each separate head of the cyst, and there may be thousands in a single cyst, develops into a tape-worm. It is probably the smallest tape-worm known, having very few segments, and only the last segment is gravid with eggs. The dog scatters the eggs of this tape-worm broadcast and the domesticated animals become infected with it. Mankind may also become infected with this parasite by a too close intimacy with dogs. In Iceland where men and dogs live during the long months of winter in the same huts and without any idea of sanitary precautions, it is said that one person out of 43 is affected with the echinococcus disease. In some parts of Germany the disease is also very frequent. Ostertag gives a table from which it appears that at Rostock out of 1026 post-mortems on man 25 cases were found, or 2.43 per cent.; at Breslau out of 1360 post-mortems there were 20 cases, or 1.47 per cent.; at Berlin out of 4770 post-mortems there were 33 cases or 0.76 per cent. It is also alleged to be common in Siberia, India and Australia. The disease can only be controlled by careful meat inspection and the destruction of all hydatids that are found. Unfortunately the local slaughter-houses of this country are not looked after so closely as they should be. It is often an easy matter for dogs to gain access to such premises and to become infected with this parasite and thus propagate the infection. To prevent this and other diseases there should be expert supervision over all slaughter-houses. Places for slaughtering should be reduced in number so that all the butchers of a town or village would slaughter at the same place and the premises where slaughtering is done should be under the surveillance of the local board of health. Offal feeding should be done away with in order to prevent the propagation of this class of parasites, and under no circumstances should a dog ever be allowed on the premises.

I trust this brief and somewhat superficial review of the subject of meat inspection, and the exhibition of specimens, may serve to increase the interest of physicians in this branch of sanitary work. It is only through the examination of the pathological specimens actually found by the meat inspectors that we are able to appreciate the importance of having experienced and educated men on guard to withdraw carcasses so affected from the meat-supply of the country. The great mass of our citizens have no conception either of the diseases found among animals at the abattoirs, or of the enormous amount of work which our government is doing to protect them from diseased animal products.

No public work, however, can long be sustained or carried to the highest degree of efficiency unless the people of the country understand its objects and value and become interested in it. This being true as a general proposition, we can hardly expect the meat-inspection service, interfering as it must more or less with some of the wealthiest and most powerful industrial organizations in the world, to be conducted with vigor and a rigid adherence to correct principles, unless there is a popular appreciation of the value of the work to every consumer of meats. This service must appeal first of all to the physician, who, being familiar with pathological appearances, can by inspecting these specimens judge of their seriousness and their influence on the public health.

Non-alcoholic insanity is decreasing in Scotland, while alcoholic insanity is increasing, according to the past year's records of the Edinburgh Asylum for the Insane.

THE TREATMENT OF PROLAPSE OF THE RECTUM.*

JOSEPH M. MATHEWS, M.D., LL.D.
LOUISVILLE, KY.

There is perhaps no pathologic condition which affects the rectum, that gives so much concern to the surgeon, as a serious prolapse. It is not to be understood that reference is had to the prolapse that occurs in infancy or to the milder forms met with in adult life. I have yet to see a prolapse of the rectum, incident to young life, that has not readily yielded to the following simple plan of treatment, viz.: Administration of a gentle purgative and, when it acts, the protruded gut is washed with cold water and returned. Then the physician in attendance straps together the two buttocks, bringing them in close apposition by means of adhesive plaster. This is allowed to remain on for four or five days, and the little patient is kept in bed and permitted to have only liquid nourishment. At the end of this time the adhesive strips are removed and the bowels allowed to move in response to a dose of castor-oil and an enema of cold water. The child should be allowed to have its action from the bowels while lying on the back. The adhesive plaster strips are then reapplied and the child put to bed for another five days—the purgative is again given, when it will be observed that the gut will no longer protrude if the proper attention is given the position of the patient during the action of defecation, which should be either in the erect one or reclining upon its back. The application of fuming nitric acid or other caustics should be deprecated in all such cases.

LINEAR CAUTERIZATION.

Linear cauterization is recommended by some, notably Van Buren, in his most excellent work on "Diseases of the Rectum." It was advised by him to use the actual cautery-iron in most all cases of prolapse of the rectum. The truth is that the remedy is too severe to use in simple cases, and is of no benefit in the graver ones. Its application would often result in hemorrhage if the iron is applied sufficiently hot to cause a slough, and unless a slough does occur, no benefit is derived from this mode of treatment.

AMPUTATION.

The former custom of cutting out an elliptical piece of the gut and drawing it together by sutures is so unsatisfactory in its results that it will not be discussed here. Amputation of the "prolapse" is, however, an operation advocated by a good many and should receive careful consideration. We must remember that it is often a difficult matter to tell just what kind of a prolapse is being dealt with. A prolapse of mucous membrane alone can be amputated and tied off, just as hemorrhoids are treated. But to cut off a more serious prolapse, means the opening of or the wounding of the peritoneum with perhaps dangerous complications, not to speak of subsequent contraction as the result of the amputation. This phase of the subject has been carefuly considered by modern operators, and I beg to call attention to a recent report of such a case by Dr. George Ryerson Fowler[1] of New York. He says:

> In a case of large rectal prolapse recently under my care at the Brooklyn Hospital, the following method of carrying out the procedure of amputation of the prolapse proved to be comparatively easy of performance, and was followed by a most excellent result. The patient was a male in whom the

---

* Read before the Chicago Medical Society by invitation.

[1] Med. News, Dec. 8, 1900.

mass protruded about five inches, and had been in existence for five years.

Analgesia was effected by means of spinal cocainization. The patient was placed in the combined lithotomy and Trendelenburg position. Being fully conscious, he was able to bear down forcibly and extrude the prolapse fully, thus doing away with the necessity for traction upon the latter. A row of fenestrated or ring-headed forceps (common artery clamps will answer, but do not hold so well) was placed just in front of the junction of the mucous membrane with the skin of the anus in such a manner as to pinch up a circular fold of the mucous membrane of the outer cylinder for the entire circumference of the gut. About half an inch in front of this again an incision was made, likewise for the entire circumference of the outer cylinder of the gut, this incision extending through the mucous membrane only. Its proximal edge was dissected back for a half-inch. Two clamps were now placed, one upon either side, at the point of the prolapse, or the place where the outer cylinder of the gut returns to form the inner cylinder. With the mass thus steadied and the two cylinders identified, the index finger of the left hand was passed up the inner cylinder, and with this as a guide the cylinder incision already made in the circumference of the outer cylinder was deepened to the extent of a half inch so as to include the remainder of the thickness of the latter and the inner cylinder through its entire thickness to the finger inside the latter. A suture of catgut was now placed so as to include the entire thickness of the two cylinders where the half-inch opening was made, with the exception of the turned-back mucous membrane cuff at the anal mucocutaneous margin grasped at first by the fenestrated forceps. This step of the operation was repeated until the entire circumference of the cylinders was transversed, save that each subsequent suture was first applied and the incision extended afterward. Care was taken that each extension of the incision was carried no farther than the area previously secured by the suture. Throughout this portion of the operation a stream of warm borosalicylic (Thiersch) solution was kept playing upon the parts. When the posterior portion of the circumference was reached the mesenteric attachment of the gut was encountered. This was treated precisely as the interior portion, no difficulty being encountered in securing the vessels of the mesentery in the suture. As the last suture was applied the final cut was made in front of it, completing the amputation of the prolapse. The dissected-back mucous membrane at the mucocutaneous margin, which up to this time had been held in the grasp of the forceps first applied, was now replaced and sutured in position over the first rows of sutures. Alcohol-boiled catgut was used as suture material throughout the entire operation. The patient suffered not the slightest pain during the entire operation, nor inconvenience either then or thereafter from the spinal cocainization, save slight nausea and mild headache.

An opium suppository was placed high up in the bowel, and the parts replaced. A light tampon of zinc oxid gauze was placed in position for forty-eight hours, after which it was removed and a castor-oil cathartic given, followed in three hours by a sweet-oil enema.

The advantage of this method consists: 1, in the use of the combined lithotomy and Trendelenburg position, in order to prevent the descent of the small intestines during the operation, and thus providing against injury to these during the suturing; 2, in *turning back a cuff* at the mucocutaneous margin for the purpose of preserving the normal conditions at the rectal outlet, and at the same time permitting the removal of all the relaxed and overstretched mucous and submucous structures at this point. This cuff also provides a covering for the sutured edges of the stump of the prolapse and diminishes opportunities for subsequent infection; 3, in the step-by-step application of, first, a suture and then an extension of the incision through both cylinders to correspond with the sutured area, in this manner avoiding exposure of the peritoneal cavity to infection.

It is not claimed that this operation possesses all of these advantages exclusively. Several of them are features of one or another operation. I do not remember, however, to have seen them all combined in one procedure before.

Whereas Dr. Fowler does not claim that the operation is an original one in all its details, it does possess unique features and was attended by a brilliant result. However, there are some formidable objections that could be urged against it, but the scope of this paper will not permit. I have for many years been interested in the study of this affection, and have tried many if not all the plans of treatment for its cure, and must confess to disappointment in them all as a rule. The matter of curing a formidable prolapse of the rectum in the adult is no simple matter, and simple means will not avail. It was after several complete failures that I determined to try an original plan—at least so far as it was known to me—viz., to open the abdomen and anchor the colon or flexure for the cure of a long-standing prolapse of the rectum. Before reporting this case I desire to mention one reported by Dr. Chas. P. Noble,[2] of Philadelphia, who says:

> Marked prolapse and inversion of the rectum in adults is a condition which is well known for its intractable nature and for the difficulty of effecting a cure. It is not my purpose

---

[2] Am. Gyn. and Obstet. Jour., December, 1900.

to discuss the etiology of the condition nor the treatment of the recent and more simple cases, which can often be cured by the removal of the cause, and careful attention to the regulation of the bowel movements. I desire to advocate a simple method of operation which promises well in the treatment of intractable cases, and to report two cases in which this operation has been performed. The operation which I would propose is to open the peritoneal cavity by an incision made through the left rectus muscle slightly below the promontory of the sacrum, to search for the sigmoid or for the rectum and to make traction upon it until it is inverted and until "the slack" has been taken up. The point at which the lower portion of the rectum will come in contact with the abdominal wall on slight tension should be determined, and this point attached to the abdominal wall by three or more fine silk sutures. The sutures should be passed so as to include a portion of the rectus muscle, and should pass under the anterior longitudinal band of the rectum. In this way the bowel can be firmly attached to the abdominal wall with the least danger of penetrating its lumen and with the greatest prospect of permanent attachment. The abdominal wall should then be closed by the tier method.

The history of the two cases is as follows:

Mrs. I., aged 35, primipara, consulted me March 21, 1899. She complained of backache and a feeling of discomfort about the rectum, which she attributed to piles. She stated that she had had piles for about five years and that these came down, and gave her a great deal of annoyance. The general examination threw no light upon the local trouble. Her health was otherwise good. Her bowels were obstinately constipated. Upon examination the supposed piles proved to be inverted rectum. Because of the unsatisfactory results which are usually obtained from the various direct operations upon the protruded bowel, I determined to perform a proctorrhaphy, which was done two days later. She made a prompt recovery, and was discharged from the hospital March 25. Her physician has told me within a month that the operation has effected a permanent cure. She is perfectly well, with the exception that there is some tendency to constipation, for which it is necessary to administer a laxative.

Miss D., aged 19, consulted me March 13, 1900, complaining of a sense of weight or bearing down about the rectum and intense backache. During each bowel movement there is an inversion of the rectum. For some time she has had but little control over her sphincter muscle. The present trouble began three years ago, after an attack of constipation, for which she took a powerful cathartic. Her bowels are constipated, but otherwise there is nothing in the history bearing upon the local trouble. Upon examination the sphincter was found in a paretic condition. In the Sims' position or in the knee-elbow position it dilated under atmospheric pressure, so that the rectum filled with air. Examination with the proctoscope showed a relaxed rectum, which was otherwise normal. On April 16 proctorrhaphy was performed. The patient made a good recovery and was discharged about five weeks after the operation. She consulted me in November, seven months after the operation, and reported that she had no trouble with her rectum until within a few weeks, since which time there has been some tendency to eversion of the bowel at stool. She is still constipated and has not taken her laxatives regularly. Upon examination, the anus was found in normal condition, the bowel in situ and, so far as an examination could show, the operation was entirely successful. As against this we have the statement of the patient that there is a tendency to recurrence of the old trouble. It is my judgment that reasonable care in the administration of laxatives and the use of enemata, so as to avoid constipation and straining, will be sufficient to effect a permanent cure.

When I operated on the first case, March 23, 1899, I was under the impression that the operation was original with myself. I have since learned that it has been done by Dr. W. Jos. Hearn, of Philadelphia, in one case with good result. Probably the first surgeon to perform this operation was McLeod, of Calcutta (B. K. McLeod, F.R.C.S.E.: "A New Operation for Prolapse of the Rectum," Lancet, vol. ii, p. 117, 1890). The technique which he employed, however, would not be likely to appeal to most surgeons. He introduced his hand into the rectum, reduced the inversion, put the rectum on the stretch from below upward, and pressed the rectum against the abdominal wall, endeavoring to press the small bowels to one side so that the rectal wall would come in contact with the abdominal wall. Two acu-pressure pins were introduced through the abdominal wall and through the rectum, penetrating its lumen, so as to fasten the rectum to the abdominal wall. These pins were separated by an interval of three inches, and they were so introduced that the rectum was made to take the course of running from below upward and from within outward. Having fixed the rectum to the abdominal wall, an incision was made between the pins down to, but not through, the parietal peritoneum. The hand was again introduced into the bowel as a guide, and fine sutures were introduced through the abdominal wall, and through the wall of the bowel, avoiding its mucous membrane, and then out through the opposite side of the wound. In this way the rectal wall was attached to the abdominal wall. The acu-pressure pins were removed after twenty-four hours. The patient made a fairly good recovery, the wound healing by first intention. The result was a cure.

It will be noticed that the cases reported by Dr. Noble were not types of prolapse even of the second degree, and in no way compare with the report of my case in severity of symptoms or extent of the affection.

On April 17, 1899, Mr. G. N. McL. was referred for operation, by his family physician. He gave the following statement of his case by request.

In February, 1865, while in camp and on line of duty at Fort Fisher, N. C., and on the marches through the state, I contracted a chronic diarrhea, which, with short intermissions, continued for many years, often confining me to bed. The prolapse commenced shortly after taking diarrhea and I was never entirely well of it afterward, but continued to get worse until, in 1875, when I quit all kinds of manual labor. From 1875 to 1885 I grew much worse, being much weaker and miserable. Diarrhea was bad by spells. From 1885 to 1895 diarrhea almost ceased, but the prolapse was much worse. From 1895 to 1899, diarrhea was less, prolapse much worse, though I was not confined to bed, but required a nurse most of the time. I was operated on April 17, 1899.

On examination it was found that the patient was suffering from an immense prolapse, in size about the measurement in circumference of a No. 7 Derby hat. (See photos.) It contained all the coats of the rectum, peritoneum, and in addition the bladder. In determining the method of operation, the fact of the presence of the bladder dissipated any idea of amputating the mass. When I made a statement of the formidable operation that might be required to effect a cure, he replied that life was a burden to him and that he would take any kind of a risk. After thorough preparation, he was placed under chloroform, and the bowel made to protrude to its fullest extent in order to examine it more fully. The thickness of its walls was truly amazing, and had the effect of making me doubt whether so heavy a mass could ever be held in place. An incision was made in the left inguinal region, extending upward about six inches. The hand of a competent assistant reduced the mass and was pushed with it up the rectum until the fingers could be felt in the sigmoid flexure by the operator. This procedure was found to be of wonderful assistance during the operation. The gut was now drawn taut and anchored to the abdominal muscular wall by a running suture of chromotized catgut for fully three inches. Simple anchoring by the interrupted suture would not have availed anything I am sure, in this case. The abdominal wound was closed, the patient put to bed, position on the back, with the foot of the bed elevated. He was kept in this position for two weeks, with watchful care. The bowels were moved on the fifth day by an aperient assisted by an enema. This was repeated in another five days. At the end of two weeks he was allowed to change position and recline on his side. The rectum was irrigated with a simple antiseptic solution every day. In the act of defecation, he was directed to always use the bed-pan during this time. At the expiration of a month his bowels moved on the commode without protrusion. I should state that after all the mass was pushed back, there was found to still protrude, mucous membrane about the size of a case of well-formed internal hemorrhoids. This proved fortunate, for by its simple ligation, a strictured condition resulted which was of great service at the anal orifice. It can be quite understood that the sphincter muscles were so distended by this great mass as to be nearly unrecognizable and without power of control.

The question naturally suggested was whether the muscle would ever regain its power and, if so, to what extent? Also, would this wonderfully thickened gut ever be thinned to assume or approximate the normal. I am glad to report that both conditions were eventually brought about. About one year after the operation was done I examined him, in company with Dr. Geo. J. Cook of Indianapolis, and found good contractile power in the sphincter, and the gut thinned to nearly a normal condition. On June 25, about two months after the operation, the patient wrote: "I have been using the water-closet, and there is no indication of the bowel coming down." He has continued to improve ever since and gained much in flesh. This case has never been reported.

I conclude: 1. That in all cases of prolapse of the rectum of the second or third degree, colopexia is to be preferred to all other procedures. 2. That it is the least dangerous of any surgical procedure advised for prolapse. 3. That the uninterrupted suture should be used in preference to the interrupted, especially in cases when the mass is large or the walls of the gut much thickened.

Mr Carlyon,[3] of London, says that he has only been able to find three cases of colopexia operations. He does not intimate for what degree of prolapse these were done. The operation referred to by me was done in April, 1899, and at that time I had never heard of its being done. Though, therefore, not original with me, I thought at the time that it was. No case that I have yet heard of compares in magnitude to this one, and I trust that by now reporting it, two years after the operation, the said report may prove of some benefit to those desiring to operate for so formidable a malady. In 1889, Jaennel fixed the colon to an artificial anus wound in the iliac region. Bryant found records of twenty-nine cases done by this method. In my opinion this procedure is not only unnecessary, but unjustifiable. Dr. Bovée, of Washington, reports an interesting case of colopexia done on a woman during an abdominal section after the ovaries and appendages had been removed.

In reporting this case I desire to thank my friend, Dr. Ap Morgan Vance for valuable assistance and suggestions.

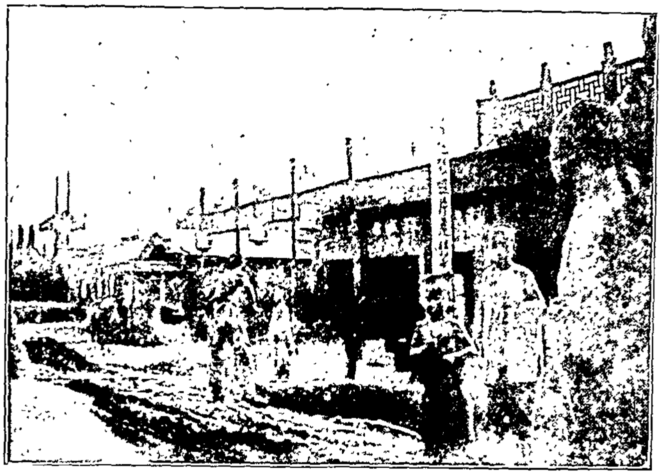
SANITARY CONDITIONS OF PEKING.

JOHN INGLIS, A.M., M.D.
MEMBER OF THE AMERICAN MEDICAL ASSOCIATION.
PEKING, CHINA.

The Chinese army has been driven from Peking, the Empress and her co-conspirators have fled, the order is cut for the punishment of the most guilty and the sacred city, we are told, is well patrolled by the foreign soldiers. All true, but those who have lived in Peking know that within a year, unless certain measures are taken, officers and men will discover a deadlier foe than the Empress Dowager's imperial troops, and the death-roll will be longer than it was after the taking of Fort Taku and Tien-Tsin.

Population.—The population of Peking is unknown, perhaps not being so great now as before the recent uprising, but still close to the one million mark. Some writers have greatly overestimated the number of inhabitants in this famous old city. Peking lies near the fortieth degree north latitude, ninety miles from the sea and one hundred and twenty feet above sea-level. It is surrounded to the north and west with mountainous hills, to the south lies the great plain of central China; the latter is sandy but well watered.

Climate.—The climate is similar to that of New York, but much more trying, especially during the spring and summer. From November until March the weather is cold, but March is windy there as elsewhere, and sand storms blow over the city; these are not only disagreeable, but dangerous. In April the temperature rises and in May reaches 90 to 95 degrees F. During May and June thunderstorms and rains are to be expected, and these are frequently the forerunners of an almost continual downpour which lasts from July to the early part of September. The annual rainfall[1] varies from 46 to 76 inches, but after the rainy season is over, with the exception of some very dusty days, the fall weather is delightful.



Street Sprinkler.

Water Supply.—A study of the sanitary conditions of Peking reveals much of a threatening nature and, if it teaches nothing new, throws indisputable proof in favor of our present ideas concerning the causation of disease. The city is without water-works, and has no sewerage system worthy of the name. The Chinaman believes in open sewers, claiming that it is better to leave the foul gases free than to pen them beneath the ground. But whether this is based on some scientific theory not yet explained, or ignorance of refuse disposal, I can not say, but am inclined to attribute it to ignorance. The water-supply is from wells dug along the sides of the streets; a heavy stone covers the well's mouth and the water is drawn in wooden buckets by rope and pulley; the presence of an open sewer ten feet away, or even running by the mouth of the well, in no way seems to militate against the site on which to sink a well. How often these wells are cleaned out it is impossible to learn, but it may be safely affirmed that they are cleaned only when enough dirt gathers in the bottom to interfere with the filling of the well. The water itself is

A Cesspool on one of the Main Streets.

---

[3] The Lancet. December 1899.

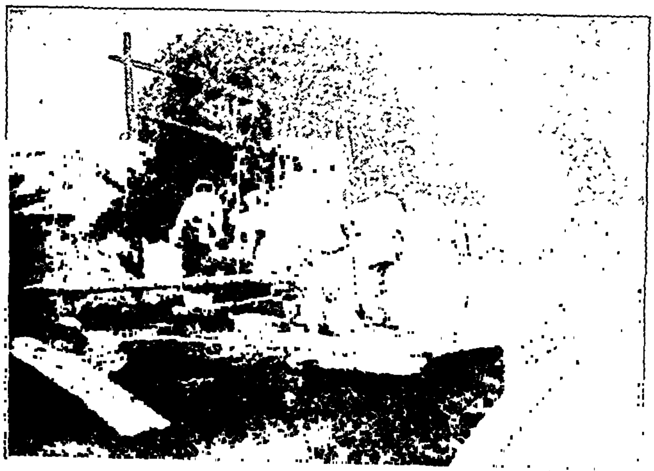
[1] There is no official record. This is the average for a number of years past, taken by different observers.

clear and of two varieties, known as "sweet" and "bitter" water. The latter is due to an excess of alkali containing 22 per cent. of hardness, as shown by examination. The use of this water means a great deal of kidney trouble. In one year, in a Peking hospital, I have seen more Bright's disease and stone in the bladder than in almost three years spent in connection with much larger hospitals in the United States. Fortunately the Chinese have learned by experience that "raw" water is not good for them, and consequently drink it boiled and colored with a very weak tea.

Street Sprinkling.—The street, or traffic way, which is simply an unpaved mud road, is the common receptacle for rubbish, offal and excrement. It is sprinkled—when sprinkled at all—by hand. For this purpose no water can be too filthy. In fact, the cesspool by the roadside is the common source of sprinkling water.

House Sanitation.—Here we find no alleys as in American cities; each residence is surrounded by a wall, and one compound may contain numerous houses. All the refuse of bedchamber and kitchen finds its disposal upon the street or into an open sewer, where it decays immediately below the surface of the ground. It must be said, however, that the Chinese kitchen has practically no waste compared with the American. A potato paring is too valuable an article of food to be lightly thrown away.

Every day the manure gatherer may be seen, with a large keg suspended from his shoulders, trudging along the street gathering up the deposit. Here is to be found one of the most disgusting and unsanitary systems in the world; this excrement from man as well as beast is carried to different quarters of the city and prepared for agricultural purposes. From the sanitarian's point of view this does not need to be dwelt upon; such places are the charnal houses of disease, seething cauldrons disseminating poisonous vapors to be wafted over the city.



A Street Well.

Abbattoirs.—In front of meat shops the animals are killed upon the earth thresholds. In fact, on almost any walk along the street the whole process of the abbattoir may be seen.

Former Sanitary Efforts.—Here we have an open violation of the tripod of modern sanitary science, sewerage, water-supply and the disposal of refuse. At one time in the history of the city an effort was made to build large sewers, and the masonry of those they built is creditable; but the system was not general, and that which they did build has fallen into decay. there being little or no effort to keep it in repair. Here and there these old sewers serve a good purpose, but for the most part the refuse and waste water stand reeking in them and in the cess-pools until the stagnant matter is again thrown upon the street by the street sprinkler, to again disseminate its poison into the air.

Peking's Scavengers.—Peking is pre-eminently a city of dogs—large, savage-looking mongrels, but of cowardly spirit. These animals, while the vilest creatures ever seen, eat anything short of mortar and brick, and contribute greatly to the disposal of refuse; while their presence is a menace to public health, they are of positive usefulness in a city such as the Chinese capital. With these must be mentioned the black hogs of China, which run the city streets unmolested; they are the city scavengers, but add a great element of danger to the health of such a densely populated district.

The Houses.—The dwelling-houses are devoid of anything like a cellar. the floor being laid upon the ground and made of porous brick. Among the poorer classes, the floor is the ground itself. These permit of no circulating medium beneath their apartments, and the gases arising from the earth find ready access to the dwellings. Second story residences are unknown, except those built by foreigners. The windows of the Chinese house are made of lattice-work covered with thin sheets of paper. The rooms are heated, when heated at all, by very small earthenware stoves, in which they burn coal balls made from anthracite coal dust and mud. The rooms are often filled to a dangerous degree with coal gas; thousands of the Chinese die every year from asphyxiation, and it is in these houses with these accommodations that our troops have spent the long cold winter months in China.

Peking's [illegible] from all sanitary measures as a means of [illegible], nothing can take the place of bodily cleanliness. Beggars, ill-clad and filthy beyond description, cluster around the city gates and sit on every corner. A few years ago, a Chinese official states, in one night four hundred of them froze to death. This number has been greatly exaggerated, but the best Chinese authorities place it at the above figure. These beggars sleep in gateways, or wherever they find it convenient. Whatever may be said of them from the philanthropic point of view, where their number is legion, they are disseminators of disease, and must be placed among the evils to be removed in placing the city on a sanitary basis.

Disposal of Dead.—In the disposition of the dead Peking has reached the limit of human abominations. If the deceased be wealthy the corpse is kept in the courtyard for weeks. When the day comes for interment the only bearers who can be found to carry the coffin are the beggars, and the wealthier the family the more beggars they add to the procession. The most gruesome sight in connection with this subject is the method in vogue among the poor of disposing of their dead children. Too poverty stricken to provide a funeral, and holding the superstition that a child who dies before the age of 10 must have been inhabited by a demon, the parents or guardians wrap the body in a coarse straw mat and throw it into the street during the night. At daybreak the dead-cart, drawn by an ox, passes along and the driver gathers up these little cast-out infants and children. It not infrequently happens that an unwanted new-born baby still living is found, and it is taken with the rest and all are buried in a heap outside the city. The disease of which the child dies is a matter of no consequence, the manner of burial being the same. The ox cart is sometimes assisted by barrow men. A wheel-barrow with double baskets full of little dead smallpox patients was seen one day two years ago down near Legation street. The baskets were full to overflowing, with no covering over the dead, on whose disfigured faces the hot sun was shining.

Means of Conveyance.—The common mode of conveyance in Peking is a mule cart large enough for one passenger to get into and sit upon a padded cotton seat or a fur rug on the cart floor. In them is often to be seen an individual broken out with the smallpox, and the next occupant may have something little better. Cart stands are numerous, and it is safe to say that no carter ever refuses a passenger because of any known disease. No sanitary view of this capital would be complete if it did not consider the influence of these conveyances on the public health.

The itinerant barber is another prolific spreader of diseases peculiar to his trade. The terrific dust storms no doubt carry with them much infection from point to point. A physician who has practiced here for many years has said that the inhabitants of Peking who survive live only by the incessant warfare that goes on between the bacteria themselves, and the ever-faithful phagocyte endeavoring to save us from the disease germs. But here the former is waging a war against terrible odds.

An Object-lesson.—An American bishop who visited Peking recently stated that, on entering the city, he distinguished seventy-two distinct odors. Peking is an appalling object-lesson to those who think too much money is expended in the support of our American boards of health. Any physician who reads this paper can tell, given such conditions, what will be the diseases prevalent. They are such as are to be expected from these surroundings. Cholera is a frequent visitor, cholerine lives there, smallpox is not epidemic but resident, diphtheria is a dreaded foe, typhoid and typhus fevers with malignant malaria and dysentery are always present, and consumption slays its victims by thousands every year. There is also a multitude of skin diseases. In short, every germ-produced disease, and the non-microbic as well, capable of flourishing in this latitude, find their home in this Chinese metropolis. The infant mortality is enormous.

If the powers intend to hold Peking for any length of time it would be wise to add to that misty antiquity and ancient culture which the present Chinese minister, Mr. Wu Ting Fang, dwells upon so persistently, a chapter on sanitation and approximate cleanliness of people and city; at the same time insure to a greater degree the health of our troops stationed there in the interest of a better civilization.

One of the conditions that ought to be required of China before admitting her to the society of enlightened nations is that she shall make her capital less dangerous as a place of residence by ridding it of the insanitary conditions that give rise to the enormous prevalence of those diseases that are the product of filth—a remnant of unenlightened ages. Sanitary science applied to Peking would make it as healthy a city as New York or Chicago.

THYROID TISSUE IN THE LARYNX AND TRACHEA.*

OTTO T. FREER, M.D.
Instructor in Laryngology and Diseases of the Chest, Rush Medical College; Professor of Laryngo-Rhinology, Chicago Policlinic.
CHICAGO.

Up to the present time nine cases of thyroid tissue growing within the larynx and trachea have been reported. The histories of these have been collected by Baurowicz, who reports one of his own together with these, in Fränkel's Archives of Laryngology and Rhinology, volume viii, 1898. I have been unable to find a description of the affection since the publication of Baurowicz's article, so think that I can claim that the case of my own that I shall describe is the tenth recorded of this rare affection. Up to the present time the cases reported are 3 by Paul Bruns, 2 by Heise from Bruns' clinic, and 1 each by Ziemssen, Paltauf, Baurowicz and Roth. The principal symptom caused by thyroid tissue in the larynx and trachea is dyspnea. This may have lasted for years, months or weeks before the patient is seen, and generally there is a history of rapidly increasing difficulty of breathing for the last weeks before aid is sought. In a large proportion of the patients tracheotomy is needed to save life. The voice generally does not become hoarse or lose its clearness, as the growth does not ordinarily extend above the lower larynx high enough to interfere with the vibrations and mobility of the vocal cords. An exception to this was in the case of Baurowicz, where one cord was found immobile. Enlargement of the thyroid gland is not a necessary accompaniment of the disorder, but a goiter is quite often present. The thyroid tissue in the larynx and trachea does not cause catarrhal symptoms or irritation, and the dyspnea alone makes us aware of its presence. Where the narrowing of the lumen of the larynx or trachea is sufficient, stenotic breathing becomes noticeable. The ages of the patients vary between 15 and 30 years. The thyroid tissue forms a swelling of variable extent, at times a single tumor being found the size of a pea or bean, other cases presenting diffuse outgrowths occupying a great part of the lower larynx and extending into the trachea.

The most constant situation of the neoplastic swelling is the interior of the cricoid ring. From here the growth is found prolonged into the trachea to a variable distance, the extreme so far found being the fourth tracheal ring. The mucous membrane over the outgrowth is normal in appearance and usually smooth, but in some parts it may present an irregular surface. The tumor has a broad base which merges insensibly into its surroundings. No case is recorded where it was pedunculated. In some cases the thyroid tissue takes the form of a diffused swelling rather than of a definite tumor. This was notably the condition in my own case. As an exceptional site, the location of the growth in the trachea only, without involvement of the larynx, may be mentioned. In all but two cases the tumor was seated on the posterior and lateral wall of the lower larynx and trachea. In one it occupied the anterior wall of the trachea just under the thyroid isthmus. The new-formed tissue is nearly always extensive enough to cause serious dyspnea, great enough at times to necessitate immediate tracheotomy.

The laryngoscopic appearances of the growth usually show a smooth prominence below the vocal cords, over which they move freely and to which they do not seem to be attached. The swelling occupies the hypoglottic space on one or both sides or posteriorly, and in some instances may be seen extending down the trachea in a shadowy way, as the growth in the larynx permits but little light to pass below it. The swelling has a normal color and shows no evidence of inflammatory conditions.

ENTRANCE OF THYROID TISSUE INTO LARYNX AND TRACHEA.

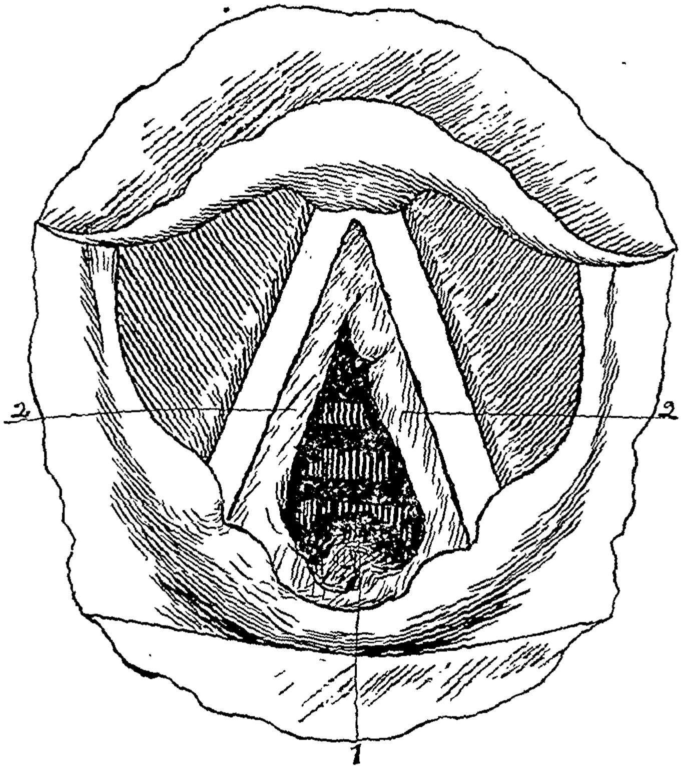
How does the thyroid tissue enter the larynx and trachea? Up to the time of the report of Paltauf's case the accepted theory was that this thyroid tissue was due to aberration of the embryonic rudiments of the thyroid gland producing an accessory thyroid gland in the larynx, such as is rather often found at the base of the tongue. The postmortem examination of Paltauf's patient, however, showed that this theory was untenable. The moderately enlarged thyroid gland in his case was found firmly grown onto the cricoid cartilage and the first three tracheal rings so that dissection was needed to separate it. This differed from the normal conditions where the larynx and trachea are separated from the thyroid gland by a layer of areolar tissue. Microscopic examination showed that the deeper connective tissue of the submucosa, and the inner perichondrium clear to the cartilage, were infiltrated with the follicles of the thyroid gland. The space between the cricoid and first ring of the trachea, with a piece of the attached thyroid gland, showed direct connection between the inner and outer tumor. The thyroid tissue could be seen to grow into the external perichondrium of the trachea and through the interstitial spaces between the tracheal rings and in this way reach and intimately join the tumor in the larynx and trachea The peripheral layer of follicles of the thyroid gland shows the most energetic proliferation normally, especially at puberty, and if the normal layer of fascia separating the thyroid gland from the larynx and trachea has been omitted in the development of the individual, the thyroid follicles are liable to invade the interstitial spaces between the cartilaginous rings and, by their infiltration, enter the lumen of the larynx and trachea. An actual perforation of the walls of these air-passages is not necessary and has so far not been found. This mode of direct invasion of the tracheal and laryngeal lumen is the one advanced by Paltauf and Baurowicz, and as it has also been accepted by Paul Bruns it seems the correct explanation of the morbid process. Bruns' latest case, in fact, was a strong confirmation of this view, as the thyroid isthmus was found firmly attached to the anterior wall of the trachea directly over the site of the tumor removed by laryngotracheotomy.

Prognosis.—The prognosis of the affection is good if the growth is removed by operation, as the new tissue shows no tendency to reform afterward and as the wound is a clean one and not one in inflamed tissue, there is little danger of complications following the operation.

---

* Read before the Chicago Laryngological and Climatological Association, Nov. 15, 1900.

Diagnosis.—The diagnosis presents great difficulties. Baurowicz thinks that fibroma, if of broad base, ecchondroma or adenoma might come into question. Though rare enough in the upper larynx, fibroma and adenoma scarcely occur in the subglottic space. One in this location, however, could only be diagnosed from thyroid tissue by the microscope. If it could be touched with a probe the hardness of ecchondroma would differentiate it, though portions of a thyroid tumor may be exceedingly firm. Cricoid perichondritis secondary to syphilitic, tubercular or typhoid ulceration presents an entirely different picture and can not come into question. Metastatic or primary idiopathic perichondritis of the cricoid cartilage might resemble thyroid tumor in appearance; the inflammatory symptoms and local tenderness accompanying these affections and the septic etiology in metastatic perichondritis ought to suffice to distinguish them. In my opinion the condition most likely to be confounded with subglottic thyroid growth is chronic subglottic laryngitis, or chorditis vocalis inferior, as it is also called. In fact, my first diagnosis of my own case was this, a diagnosis confirmed in a meeting of the Chicago Medical Society by all the laryngologists present. The points of similarity in subglottic laryngitis are the appearance of a smooth swelling in the subglottic region and a history of dyspnea with exacerbations which may have lasted a long time and which is often so great as to make tracheotomy at once necessary. The differences are the bilateral location of the swelling in subglottic laryngitis and its continuity with the vocal cords. Though the swelling in laryngeal or tracheal thyroid tumor is usually unilateral, my case shows that it can be diffuse and surround the subglottic space symmetrically, in a manner precisely like that of subglottic laryngitis. The tumefaction in subglottic laryngitis is seen to be a part of the lower portion of the vocal cord and to partake of its motions. The upper surface of the cords is also apt to show swelling and congestion, while the cords in thyroid growth are normal in appearance, almost always freely movable and not connected to the growth. Hoarseness is usually not present, while it is a not uncommon symptom in subglottic laryngitis. As a general rule the local appearances in subglottic laryngitis are those of a diffuse swelling in the hypoglottic space, while the appearance of intralaryngeal thyroid tissue is that of a broadly attached tumor in most cases. It can be seen, therefore, that the points of dissimilarity are not striking enough to permit a diagnosis in all cases without a microscopic examination.



1. Prominence of thyroid tissue on posterior tracheal wall.
2, 2. Thyroid tissue in subglottic region.

Treatment.—The treatment of thyroid growth in the larynx or trachea usually requires laryngo-tracheotomy. The inaccessability and firmness of the growth, together with its broad base, make endolaryngeal methods impracticable. If, as in my case, the patient refuses a cutting operation, relief may be afforded by removal of pieces of the tissue through the tracheotomy opening, or through the glottis if possible. After the cricoid cartilage and tracheal rings have been split as far down as the tracheotomy wound, the growth can be cut off from its base with the knife or scissors. Bleeding is not great, and after three weeks, as a rule, the wound will be found healed, without trouble. The growth can not be enucleated, as it really forms part of the tracheal or laryngeal wall, but has to be shaved off from its base.

Case.—The history of my case is as follows: The patient, a woman of 32, was first seen in December, 1897. She had had attacks of hoarseness every second or third winter since her childhood. Her voice was always a little hoarse. In the winter of 1897 she was very hoarse for some weeks, and for the first time noticed that this was accompanied by a sense of suffocation and wheezing in the windpipe. All of these symptoms left her during the summer. In December, 1897, the wheezing and feeling of choking returned, and it was so bad as to alarm her and make her fear to go to sleep. Two months later this sense of suffocation had lessened, but the stridor of laryngeal stenosis could be heard when the patient breathed a little harder than usual. Laryngoscopy showed the larynx normal above the subglottic region. The vocal cords looked natural and were freely movable. Just below the true cords one could see a thickening of mucous membrane forming a ledge which projected into the lumen of the larynx around its whole circumference, forming an irregular ring with a narrow central opening. Just below the vocal cords this ledge was most prominent, looking like a second pair of vocal cords below the true ones. The thickening, as could be seen, extended down the trachea for three or four rings, forming a prominent tumor projecting from the posterior wall and preventing vision farther down. Palpation showed almost complete absence of the thyroid gland in spite of the fact that the patient was very thin, had a long neck and palpation of its structures was therefore very distinct. The subsequent history of the patient was interesting and contained some exciting events. An attack of laryngo-tracheitis caused her so much distress on account of the accompanying swelling narrowing still more the small opening in the trachea she ordinarily had at her disposal for breathing, that she decided something must be done for her, but refused any cutting operation, so the measures taken had of necessity to be endolaryngeal ones. As I had used electrolysis in the larynx for the removal of papillomata, with success and no appreciable reaction or swelling, it seemed to me that it would offer a safe means for the removal of a portion of the obstructing swelling below the glottis. With the help of cocain, the introduction of the negative pole in needle form into the prominence was quite easy. A current of 15 milliamperes was used for four minutes, with scarcely any pain. The next day there was no noticeable reaction, but on the second, subglottic swelling developed to such an extent that it became necessary to perform immediate tracheotomy. The swelling in the subglottic space subsided after about two weeks, though the result of the electrolysis was insignificant, but a small slough coming away. I had expected a better result as a similar current in the skin would have produced a large slough. A second attempt with the electrolytic needle did not add much to the result, though the lumen left in the larynx by the subsidence of the swelling was undoubtedly larger than before the operation. As the growth on the posterior wall of the trachea seemed responsible for the greater part of the dyspnea, I succeeded in getting my patient's consent to remove as much of this as I could through the tracheotomy wound. By means of the wire snare and a pair of Fränkel's forceps it was possible to take away the greater part of the intratracheal swelling, the most prominent part of which was situated at the second and third tracheal ring; this, when seen under the microscope, proved to be typical thyroid tissue. I repeatedly seized the swellings in the subglottic region with Scheinmann's cutting laryngeal forceps, from above, but the great firmness of the tissue made it impossible to remove even the smallest piece. After this the patient went about with her tracheotomy-tube, as her experience with suffocation made her feel unsafe without it, for though her breathing could be carried on quite well without it, she feared another attack of swelling and suffocation. She still refused operative measures from without, so I attempted to reduce the subglottic swelling with the galvanocautery, and, though I succeeded in introducing a cautery electrode into the growth from above, the result was infinitesimal. It is difficult to use instruments with accuracy in the subglottic region, and the necessity of avoiding injury to the vocal cords made it possible to burn only a very little at a time. The patient finally left me, improved but not daring to take out her tracheotomy-tube. I heard of her through others whom she consulted, and presume that perhaps by this time she has consented to a laryngo-tracheotomy, the only operative measure of value in this condition, as the thyroid tissue can only be removed by being dissected out.

I hope that my description will lead to the recognition of other cases of this kind which may be less rare than supposed. The fact that my patient had no appreciable thyroid gland in her neck leads to the supposition that a great part of it at least was represented by the extensive amount in her larynx and trachea, an amount greater than in most of the cases heretofore reported. Though in the other cases the thyroid tissue is described as forming a tumor, in mine its diffuseness made such a term inappropriate, it being rather a thick lining for the entire cricoid circumference and extending in the same manner down the back of the trachea. The only tumor-like formation was the prominence on the back of this that was removed.

In a recent article myxedema is described as following the removal of thyroid tissue at the base of the tongue, so it seems possible that the thyroid tissue in unusual situations may perhaps take the place of the normal gland. In regard to the power possessed by thyroid elements to penetrate and grow in other structures than the proper capsule of the thyroid gland, Dr. Christian Fenger, in a personal communication, mentioned a case in which the thyroid tissue had penetrated the lumen of the jugular vein. Dr. Fenger regards the microscopic specimens obtained from my case as typical thyroid tissue.

My experience with electrolysis in the subglottic region would make me hesitate to use it there again unless the patient had had a previous tracheotomy. A bipolar electrode, if it could be introduced, would doubtless be better than the monopolar one employed by me. Electrolysis would be an excellent method to employ for ecchondroma in this difficult region. On account of its loose areolar tissue the hypoglottic region is much more apt to react after irritation by inflammatory swelling than the larynx proper. The connective tissue, in the specimens presented, forms a much denser network than that of the normal thyroid gland; a fact which accounts for the great firmness presented by the growth.

OPEN TREATMENT OF SUPPURATION OF THE KNEE-JOINT.*

W. J. MAYO, A.M., M.D.
Surgeon to St. Mary's Hospital; Surgeon to C. & N.-W. Ry. Co.
ROCHESTER, MINN.

In the January, 1895, issue of the *Annals of Surgery*, Dr. C. H. Mayo reported a case of acute suppuration of the knee-joint, which he had treated July 30, 1894, by a transverse incision across the front of the joint in the same manner as for excision. This enables the surgeon to get at every part of the joint, converting its many recesses into a simple open cavity. The result of the operation is astonishing. In a few hours a patient in whom an amputation seemed to be the only hope is on the road to recovery; such a procedure gives all the benefits of the mutilating operation without shock or injury to important structures. It must be understood that this method of treatment is for the more advanced cases after the usual measures have been exhausted and amputation appears to be necessary. In most instances the capsule has been perforated and the soft parts above and below the joint are infiltrated with septic material. All of the important structures are in the popliteal space, and a transverse incision through the patella enables the surgeon to pack the joint with gauze, and treat it as an open wound. By going through the patella, secondary sutures are given a firm support after the infection is under control. The abscesses, if they exist in the soft parts, are freely opened and drained. The margins of the wound granulate rapidly and in from two to three weeks, when the discharge has practically ceased, the cut patella is reunited, the excess of granulations removed and the soft parts allowed to granulate.

Surprising to relate, not all of the cases are followed by ankylosis. If the cartilage of the joint is not eroded considerable motion may be ultimately obtained, although this is a secondary consideration, as the condition is one which threatens life or limb. The reason ankylosis does not always follow is because the adhesions are developed in the same manner as a pannus projects over the cornea and, unless the cartilage is completely covered by the advancing granulation, the portion which remains smooth permits of motion. If erosion of the cartilage has taken place ankylosis will necessarily result no matter what method of treatment is followed.

For the milder cases in which the capsule is intact irrigation with antiseptic solutions or with pure carbolic acid followed by alcohol, as advocated by Phelps, is often all that is necessary. If this fails, lateral incisions, as practiced by Halsted, or tubular drains after the plan of Edmund Andrews, may be sufficient, but there are still a number of neglected cases, especially punctured wounds, in which these ordinarily satisfactory methods are entirely inadequate and the patients have in the past come to amputation or death. Open treatment by transverse incision across the entire front and lateral aspects of the joint gives all of the benefits of amputation without its risks, and saves for the victim a most useful limb. We have practiced this method for six years in a number of cases with the most satisfactory results, and in children have obtained a range of motion from 15 to 60 per cent. of the normal. In conclusion I can not do better than to cite Dr. Arpad Gerster,[1] who says that Dr. C. H. Mayo's suggestion struck him as very plausible, and he has "applied it in two cases. The result has been excellent. As all know, these acute forms of joint phlegmon necessarily end in ankylosis, if, indeed, they do not cause loss of limb or life. The cartilaginous covering of the bones forming the joint is destroyed and, therefore, ankylosis is inevitable. Knowing this fact, the surgeon in adopting this method of treatment frankly accepts the necessity for ankylosis. The road then becomes very clear. The treatment consists in laying the joint open by a transverse incision, extending from one condyle to the other, just as a joint is laid open for resection. Then as many more incisions are made as may be necessary, in order to open up every collection of pus or fluid in or about the joint. The capsule in all of these cases is very intumescent and swollen and for this reason occludes all drainage tubes in a way to make retention inevitable. Then lay the joint freely open, removing or not removing tissues, as the case may be, pack and drain every recess, and treat it as an open wound. It is astonishing how rapidly the phlegmonous process ceases when compared with other methods of treatment. After the symptoms of active inflammation have subsided, the joint is put in proper position and ankylosis is allowed to take place."

---

* Read at the annual meeting of the American Academy of Railway Surgeons, at the meeting held in St. Paul, Minn., Sept 5 and 6, 1900.

Since these remarks by Dr. Gerster, this method of operation has been applied in a large number of cases at Mt. Sinai Hospital, New York City, with the most satisfactory results.

QUANTITATIVE TESTS FOR PROTEOLYSIS.*

A. L. BENEDICT, A.M., M.D.

Professor of Physiology and Digestive Diseases, Dental Department, University of Buffalo; Editor *American Therapist.*

BUFFALO, N. Y.

(Concluded from p. 808.)

The first table herewith presented gives the results of investigations on students who were free from subjective and objective evidences of stomach trouble, except for some transient disturbances of function as noted. The test meal throughout this series consisted of 50 grams of dry bread, 5 grams of butter, and 250 cubic centimeters of cold water, taken as a noon meal and removed by siphonage from sixty to ninety minutes after the completion of the meal. In no instance were remnants of breakfast found. In eleven of the sixteen examinations, syntonin was either altogether absent or present in the merest trace. The maximum precipitate was 20/100 c.c. in 10 c.c. As the qualitative examinations showed some slight variations from the theoretic normal, it was with some surprise that the following facts were deduced: 1. The presence of a measurable quantity of syntonin, was not connected with a failure of free HCl. In every one of the instances showing excess of syntonin, HCl was present by the resorcin and cane-sugar test. Conversely, HCl had all been fixed in three of the cases which were most typical so far as amount of syntonin was concerned. Hence, no generalization could be made as to the relation between proteolysis, at this stage, and presence of free HCl. 2. The excess of syntonin was connected with no conspicuous failure of ferments. However, it must be admitted that no attempt was made to carry out a test of ferments at every examination and that our tests for ferments are exceedingly crude and unsatisfactory. 3. The excess of syntonin was not connected with an excess of lactic acid. The test employed was that with ferric chlorid masked by gentian violet, as recommended by Hewes, of Boston, and others. This test seems just delicate enough to detect an excess of lactates without reacting to the small proportion normally present after ordinary test-meals. 4. The excess of syntonin was not connected with an abnormality in carbohydrate digestion. 5. The excess of syntonin was not in relation with the amount of chyme present at the time of extraction. 6. The excess of syntonin was not due to the time at which the stomach was emptied, within the limits of sixty and ninety minutes after the meal. 7. Of the five occurrences of a measurable amount of syntonin four were in the case of one subject.

Three cases showed albumose only in traces, the remainder varied between 5/100 and 20/100, eight yielding almost exactly 10/100 c.c. in 10 c.c. of filtered chyme. This variation seemed entirely within physiologic limits and without obvious cause.

Only nine of the series were treated with phosphomolybdic acid, the earlier examinations showing only the inapplicability of tannin and unmodified mercuric salts. One of the nine cases yielded a precipitate of peptone amounting only to 40/100 c.c. in 10 c.c. of filtered chyme, but the stomach contents could not be extracted until after dilution. The remaining eight cases varied between 110/100 and 290/100. Careful study failed to explain this wide variation. Disregarding the sample obtained after dilution, the maximum and the minimum of peptone were found in stomach contents which corresponded almost perfectly in other respects. Several control tests showed that, in the absence of starch, the precipitate of peptone with phosphomolybdic acid is almost exactly six times as bulky as that obtained with tannin. Calculating with this coefficient, three more cases may be added to the eight and the conclusions drawn are corroborative of the other results, namely, that the peptone precipitate is normally between one-tenth and three-tenths of the volume of the filtered chyme, if phosphomolybdic acid is employed.

In regard to other tests carried out in conjunction with the proteolysis, one or two observations should be made. The apparent absurdity of noting an absence of free acids in general while free HCl in particular is present is explained by the different sensitiveness of the respective tests. Benzopurpurin, according to the writer's investigation, is the most sensitive of the aniline dyes for general free acidity. Next in order comes Congo-red. The others thus far employed are so far inferior either in delicacy or in distinctiveness of color change, that they need not be considered. The series of observations on normal individuals corroborates the conclusions reached by Hewes, of Boston, based on a similar but larger series, namely, that the small bulk of chyme assigned by German writers as normal, after the test breakfast, does not hold good for Americans.[1] The totals obtained by the writer varied from 35 to 200 c.c., the average being 83, at least double the amount formally taught as normal. Although every precaution was used to secure the thorough emptying of the stomachs, it is obvious that any possible error must be in the direction of minimizing the bulk of the contents.

While a larger series of observations will be necessary to determine details, especially as to the proportions of the various proteids to be expected at different times after different test meals, the following conclusions are warrantable so far as the test breakfast is concerned, the stomach being evacuated within the usual limits of sixty and ninety minutes.

[1] Boston Medical and Surgical Journal, 1897.

1. The proportions of the three stages of proteids do not vary materially during the third half-hour of digestion, nor according to moderate variations in other respects, in normal individuals.
2. Syntonin is most typically represented by a mere trace. It should not exceed 20/100 c.c. in 10 c.c. of filtered chyme.
3. Albumose, by ammonium sulphate, shows the same limits, but is most typically represented by 10/100 in 10 c.c.
4. Peptone, by phosphomolybdic acid, is most typically represented by 150/100 to 200/100 c.c. in 10 c.c., but may vary between 100/100 and 300/100.

While the precipitate by phosphomolybdic acid is peculiarly bulky, that by tannin is fairly comparable with the precipitates of the lower proteids. The use of various reagents, especially for albumose and peptone, will afford support for the most contradictory statements regarding the amount of these substances formed. Ewald's statement that very little true peptone is formed by the stomach, has already been referred to. Hemmeter, of Baltimore, on the other hand says: "In normal digestion, *one hour after the test-breakfast, propeptone,*" (albumose), "is present only in trace or, usually, is not to be detected at all." The results obtained in the present series are, in a sense, contradictory to both of these statements but comparisons can fairly be instituted only when investigations have been made following the same technic. At present, clinical students of digestion are greatly hampered in their attempts at scientific work by the lack of expert chemical authority on phases of digestion which appeal strongly to the practitioner, but have not as yet interested chemists. The chemical crudities of the present paper have not been allowed to pass as final without a diligent effort to secure corroboration or revision at the hands of local and other American chemists, but it has not been possible to find more exact information than that already given.

In considering the second table, comprising the results of examinations on pathologic cases, it should be remarked that, while the meals and the period of digestion varied widely, the conditions of digestion of dissolved particles of albumin—with which the present study of proteolysis is concerned—do not vary so widely. That is to say, when the gastric juice has attacked a particle of albumin, whatever the time after the meal, the successive stages of peptonization require just about the same delay, while the proportion of the higher products is limited by absorption. Even Boas' discovery regarding the difference of the stages of digestion of meat albumin on the one hand and of egg and plant albumin on the other, assumes relatively less importance when the various intermediate products between syntonin and peptone are precipitated by ammonium sulphate. Under normal conditions, active hydrochloric acid and ferments are present in about the same proportion during the entire period of digestion of any mixed meal, barring the preliminary hour or so. Thus while the amount of proteid food taken may modify the proportion of free HCl and while the latter factor may, in turn, exert a marked influence on carbohydrate digestion in the stomach, the conversion of albumin is not materially influenced unless, by overtaxing the capacity of the stomach, the secretion of gastric juice becomes relatively insufficient or unless a genuine defficiency or excess of secretion or some other pathologic factor is introduced. Penzoldt's investigations as to the course of digestion after the most varied meals support this theory. Rosenheim's curves of acidity for various meals show distinct differences as to abscissas of time and ordinates of hydrochloric secretion when the curves after various test meals are contrasted. But if we change the position of the perpendicular axis, in other words, allow a little longer for the preliminary stage of digestion in hearty meals, the various curves present insignificant differences throughout the active period of digestion. Thus, it is really possible to institute comparisons without demanding absolute correspondence as to kind and amount of food, time of withdrawal of sample, state of starch digestion, etc.

One possible fallacy must, however, be borne in mind. The amounts of the end-products of digestion, maltose, peptone, and probably the higher albumoses also, in the case of the stomach depend on two opposite factors—digestive activity and absorption. Thus it is always puzzling and sometimes quite impossible to determine whether a large amount of an end-product signifies good digestion or poor absorption. It ought also to be admitted—though many excellent authorities do not—that

In Cases 34 to 42, rennet test good, except in 37, in which it was lacking. Egg digestion not tried.

[1] Abundant (centrifuge broke).

we have no reliable test for absorption. The tests with potassium iodid and methylene blue involve so many unknown quantities that only a great divergence from the empiric normal standard is significant. In such extreme cases we need no scientific test. In view of the quite general dependence that has been placed on the test by titration of solutions of sugar or other absorbable substances, that have been left in the stomach for some time, a few words of refutation may be in order. As is well known, such a solution is found by titration, after siphonage, to be more dilute than when poured into the stomach. Thus it has been claimed, 1, that no absorption of water occurs through the gastric glandular membrane; and 2, that by titrating the solution and comparing with a previously established standard, absorption can be accurately measured. The writer has proved that during ordinary lavage an amount of water, equal approximately to the total contents of the stomach, is lost either by absorption or by passage through the pylorus. Judging by auscultation, the escape of liquid through the pylorus under any circumstances short of nearly complete closure, is an important factor. While loss by absorption from the stomach is usually mainly of soluble solids, not of water, it is by no means certain that the stomach never absorbs water and the assumption of such a hypothesis is prima facie evidence of the unreliability of a quantitative test. In the case of R. B., of Table 2, the test meal was diluted by gastric juice to the extent of about 100 per cent. It is altogether likely that a similar dilution would have followed the introduction of a solution of an absorbable substance introduced to test gastric absorption. Even if the test solution happened to be of the same bulk when withdrawn as when introduced—not counting the increments of water used in this method to insure thorough evacuation—it would be altogether probable that there had been loss of volume by passage through the pylorus and compensatory secretion. To speak in mathematical terms, the loss through the pylorus, the removal by absorption and the addition by secretion are unknown quantities. Furthermore, they are irregular variables that are not functions of one another. Yet the attempt has been made, not only to make these three variables constant quantities, but to assign a definite value to one of them, through the solving of one equation, involving knowledge of the original strength of a solution and its content after removal from the stomach after a certain delay.

Referring to Table 2, it may be of interest to discuss the cases somewhat in detail. The case of R. B. was one of supersecretion and, essentially, of hyperchlorhydria. Although the proportion of free HCl was not beyond the normal maximum—unless we accept the very low standard of hydrochloric acidity adopted by Dr. Reed, of Philadelphia, and some others—the formation of acid by the gastric glands was actually large and the symptoms included local irritation of the gastric wall as part of the local condition present. The digestion of starch was about as would be expected *a priori*. The abatement of the hyperchlorhydria is seen rather in the diminution of the total volume of the stomach contents than in a percentage change of acidity. Throughout all five tests the proportion of syntonin was at the normal maximum, as if the first stage of proteolysis, which is essentially one of saturation with acid, had been crowded on the later stages. The variation of albumose was within normal limits, but no satisfactory explanation of the difference between the several examinations can be advanced with our present knowledge, unless, perhaps, to suggest that, as the time after the meal increases the intermediate stages are more rapidly passed through. The fact that the amount of peptone varied in general according to the amount of stomach contents might be interpreted to mean that the excess indicated poor absorption rather than good digestion, still the variation was within normal limits.

The case of J. L. J. was also one of hyperchlorhydria, but without supersecretion. The titration of the second sample was repeated to verify the unusually high acidity which is the maximum observed by the writer in any case.

The case of F. J. O. represents, for the first three examinations, diminished motility. The case was originally one of atonic dilatation of the stomach with achlorhydria, but, at this time, the stomach had returned to normal size and the hydrochloric secretion had been nearly normal for some weeks. It is scarcely necessary to state that the emptying of the stomach on these three occasions was undertaken for therapeutic reasons, otherwise more typical test meals would have been ordered. However, they do not differ materially, except in bulk, from the standard Ewald breakfast or the slight modification adopted by the writer. At several other treatments during this period the stomach was found nearly or quite empty. The last three test meals were taken and removed under circumstances that allow a fair comparison with Table 1. Unfortunately, the loss of a reagent bottle prevented the application of the usual test for peptone on one occasion. Whether on account of the difference in meals and duration of endogastric digestion or because of the improvement that actually occurred, the second set of three examinations shows that the balance has swung from lower to higher stages of proteolysis. A comparison between the last three examinations and the results of Table 1 show that further improvement in the same direction is to be desired. (The patient has since made a good recovery.)

The case of A. W. M. was somewhat similar, but the delay of the chyme in the stomach was due to actual present dilatation. The patient came from a considerable distance and the railroad time-table prevented the use of a test-meal adapted to withdrawal after an hour. On this account the patient would take a test dinner before leaving home and have it withdrawn immediately on reaching the office. While undiluted chyme was obtained for examination, it was not possible to empty the stomach except after adding water, so that an exact measurement of the contents was impossible. Probably they did not exceed 100 c.c. in any instance. It has already been explained that even if the increment of water is measured before introduction, an exact estimation of diluted stomach contents can not be made. The relative increase of peptone coincided with marked subjective improvement and a rapid diminution of the size of the stomach. At subsequent examinations after the same meal the stomach was always found practically empty.

G. W. T., H. L. B., and B. K. represent nearly identical conditions of subacidity and atonicity. On the whole, they show a relative diminution of peptone.

In the two cases of cancer it was impossible to regulate the tests to correspond at all with the others, and they are reported merely as isolated observations which may acquire some value with a better understanding of the subject of proteolysis. The case of R. was noteworthy in two respects; the rennet test several times resulted normally while the attempt to digest egg albumin after adding HCl failed. This observation is contrary to the general belief that the two ferments rise and fall together, so that coagulation of milk may be employed as an easy, though indirect, test of peptic power. The second point deserving attention is that the patient, first seen in consultation during November, showed an increasing pyloric stenosis with obstinate constipation and the return of food and drink by vomiting. About Jan. 1, 1899, the diagnosis of cancer was verified by the finding of cancer nests microscopically in the wash-water of the jejune stomach. After this the pyloric stenosis rapidly abated, the patient gained somewhat in weight, the stomach returned to normal size, vomiting became infrequent and it is only recently (note made April 28) that the signs of stenosis have been again manifest. (The patient has since died.)

Mrs. P. had passed the test breakfast into the intestine by the end of the first hour, so that, for the next meal, meat was added. The rapidity of the passage of food through the stomach is shown here, also in that only 75 c.c. remained of a meal amounting to about 400 c.c. Her stomach was somewhat larger than normal, but under the circumstances it might be more appropriate to use the term "megalogastria" rather than dilatation to describe her condition, the latter term being usually associated with more or less gastric stagnation. The digestion of the dissolved starch had been completed and all the maltose absorbed, yet the precipitate of peptone made up half of the volume of the filtered chyme The large combined acidity, with total lack of free HCl, is probably in intimate relation with these two facts. This case shows the maximum of peptone production observed by the writer.

W. F. V. was the patient of a neurologist, referred for examination on account of complaint of gastric symptoms. The analysis and physical examination failed to reveal stomach trouble. It will be noted that the quantitative estimation of proteids, though rather high in each instance, did not pass the normal limits.

F. K., who had previously suffered from atonic dilatation of the stomach with obstinate subacidity, remained well for two or three years and then presented himself with typical symptoms of hyperchlorhydria. The result of the examination shows how erroneous this preliminary diagnosis was and emphasizes the impossibility of making accurate diagnoses of gastric troubles by symptomatology alone. Proteolysis was practically normal, though syntonin was rather high.

G. L. presented no peculiarities beyond those clearly shown in the table. It may be said in general that the pathologic series shows a higher average of the preliminary proteids and a variable condition of peptone.

C. L. B. represented what may properly be termed a nervous dyspepsia, as, even after the restoration of his gastric motor function, he continued for some time to complain of symptoms of stagnation.

J. J. M. showed at several previous examinations a marked diminution of hydrochloric acidity, even after two or three hours of gastric digestion. He had an attack of what was described by his home physician as subacute scolecitis, toward the close of his treatment for the gastric condition. The latter was regarded as an independent affection, not a reflex from the bowel, on account of a distinct history of hematemesis. In spite of this interruption, the subsequent course of the gastric lesion was favorable.

Mrs. J. P.'s case was remarkable in that there was not a general splanchnoptosis, in spite of the marked prolapse of the stomach—the lesser curvature being just above the umbilicus—and the movability of the right kidney. The esophagus was dilated, 250 c.c. of distinctly esophageal mucus being vomited at one time and the gastro-diaphane kinking without reaching the stomach, its stiff end of nearly two inches having turned within the esophagus.

Dr. R., in spite of considerable subjective discomfort and of the physical abnormalities of the stomach and liver, showed a good and consistent chemic condition.

Mrs. Mc.'s examination also resulted consistently, except that stagnation was not in evidence.

Notes on Chemic Examinations.—Acidity in No. 9 was taken from similar sample next day.

In Nos. 1, 7, 13, 24, resorcin and sugar used as indicator for free HCl; in others dimethyl-amido-azo-benzol. The former method is more tedious, but more accurate. Phenolphthalein used as indicator for total acidity in all examinations. Percentages refer to c.c. of n/10 NaOH solution, as compared with number of c.c. unfiltered chyme.

Diagnosis in Nos. 21 and 22 made from microscopic recognition of fragment of tumor. No. 21 died eight months after this examination.

Combined HCl by alizarin, 66 per cent. for No. 23, 25 per cent. for No. 24; in Nos. 25 and 26, free HCl perhaps disguised by presence of blood from siphonage. In No. 27, combined HCl, 45 per cent.

THE RAGE FOR RAPID OPERATING AND THE IMPORTANCE OF SAVING TIME IN SURGICAL OPERATIONS.

JOHN S. MILLER, A.M., M.D.
Ex-Surgeon to St. Joseph's Hospital of Philadelphia; Demonstrator of Anatomy, Gross Medical College.
DENVER, COLO.

The question of time consumed in surgical operations is an important one. In the pre-anesthesia days time meant much to the unfortunate victim, whose vitality or resisting power was already reduced by nauseating and depressing drugs, such as infusion of tobacco, opium, etc., given with a view to benumbing the sensibility of the patient, who was frequently held by a corps of powerful assistants, or fastened to the operating-table by straight-jackets, straps or other devices. Dexterity and speed on the part of the surgeon then were indeed desirable factors to the shrieking and suffering patient.

The introduction of anesthesia lessened the necessity for speed, and also removed the disturbing elements which may have interfered with the accurate fulfilment of delicate operations. Anesthesia, when properly induced, produces a tranquility in the patient, operator, and assistants, which is highly essential for the proper and successful progress of the operation. In this, however, many surgeons permit themselves to drag in their work, and for the time seem to forget that the state of general anesthesia is a dangerous one and that not a minute should be wasted. It is a well-established fact that prolonged anesthesia is a retarding element in the convalescence of the patient. This is the more prominently exemplified in a complicated abdominal case, in which the resisting power of the patient has been stimulated to a point when it is estimated that the patient has a chance to survive the operation. The anesthesia, exposure and manipulation of the peritoneal cavity for from one-half to three hours, with a physically bankrupt patient is a very important factor in the prognosis. These facts being accepted, time is as important an element to success as asepsis or correct methods in operating.

ommon in hospital clinics for the operator his class while leaning over his work, and, aightening up to address the students, and luable minutes are lost. the saving of the minutes and avoidance of y delays that the minimum amount of time is in performing the operation. Such methods stitute "rapid operating."

AL DISEASE AS A SOCIAL PROBLEM.*

W. C. GATES, M.D.

ROCKLAND, MICH.

tudying medicine I was taught, not only by y many, that if I would attain to the greatest success in the profession I must treat every ho presented, no matter what his social posianding, age, or other condition, as if he were with venereal disease until I had proved to the At that time I could not fully credit the t and questioned the observation of the men le it. I entered practice about ten years ago, with an average population of 500, which for ical purposes of this paper is an ordinary counge, isolated from the rest of the world and a [illegible] y city. There was no house of [illegible] hip, and no public prostitute [illegible] lers since my residence there, [illegible] e have convinced me that my [illegible] n their statement.

[illegible] terrible disease and is so recognized by hile the great majority regard gonorrhea as affection. To my mind it is tenfold more than syphilis, while both diseases cause untold g to innocent parties, and during my very limerience I have seen several blind from the disease. The year I entered the town a young man from one of the best families graduated from one of our schools; a few years later, while on a business trip outside, he contracted gonorrhea, was treated and, as he supposed, cured by a friend who had suffered several times in the same way. Soon after his return home he was married to a young woman whom I remember as a bright, robust, rosy-cheeked schoolgirl. Since then I have treated the man for stricture and his wife for all the evils following a gonorrheal infection of the pelvic organs. She is pale, anemic, a daily sufferer, and spends nearly a week out of each month in bed. Without children, in a beautiful home, she will drag out her life of misery and suffering.

A farmer's daughter, whom I remember as a beautiful schoolgirl, a perfect type of physical strength, two years ago married a man who bragged of the number of times he had contracted gonorrhea. Soon after marriage her troubles began, her strength failed and physical exertion became a source of discomfort and pain until she was unable to do her own housework. A few months ago I operated on her for pelvic peritonitis.

A year ago I knew a man, with a wife and four children, who possessed a good income and a happy comfortable home. He contracted gonorrhea, infected his wife before he knew it, became frightened and used so-called heroic treatment, and is now at Mt. Clemens under treatment for gonorrheal rheumatism, his wife is in a Chicago hospital to undergo an operation for salpingitis, the home is sold to pay the expenses, and the children are cared for by strangers.

I would ask my hearers to lay aside all prejudice and consider this subject in the true scientific spirit, going back to the fundamental underlying principles: 1, the passions actuating those who keep this evil in existence; 2, the breeding of children and the hereditary mental influence to which they are subjected; 3, the want of police and medical supervision through a morbid sentiment and a lack of knowledge in a class which wields the greatest influence.

I will first define a passion as a certain movement of the mind which not only influences, but predominates and controls the entire organism. What is the one supreme passion in man? What is the one supreme passion which actuates and controls, not only man, but all living organisms, without which, if suppressed, all life would soon cease to exist? The answer is plain—the sustenance of life. The passion which ra [illegible] t, to this and nearly equals it in power is the [illegible] n of life. If either of these passions were [illegible] life would soon cease to exist. They are laws of Nature and no arbitrary law of soc [illegible] press them or control them except to a [illegible] extent. These facts should nev [illegible] lo Prostitution finds the reason fo [illegible] ist of these passions, and if socie [illegible] from the evils arising from pr [illegible] the subject carefully and act [illegible] prejudice.

I believe much of the evil o [illegible] the acme of medical science is [illegible] that this problem is pre-eminent [illegible] of the ASSOCIATION. It can no [illegible] as she is unable to cope with it. [illegible] brought to bear on this subje [illegible] unsatisfactory. Churchmen are [illegible] ent lines, seldom taught to [illegible] theory, or to reason from effect to [illegible] largely to the sympathies and prej

---

sented to the Section on Hygiene and Sanitary Science, ifty-first Annual Meeting of the American Medical Asso held at Atlantic City, N. J., June 5-8, 1900.

they would influence. Frequently, in times past, a few individuals have made a careful study of this phase of social life and succeeded in passing laws in some communities which have greatly mitigated the evils to which I have called attention, but the church has usually succeeded in sweeping them off the books.

Prostitution has existed under every social system of which the world has knowledge. Lecky, in his "History of European Morals," says: "Under these circumstances, there has arisen in society, a figure which is certainly the most mournful, and in some respects the most awful upon which the eye of the moralist can dwell. That unhappy being whose very name is a shame to speak, who counterfeits with a cold heart the transports of affection and submits herself as the passive instrument of lust; who is scorned and insulted as the vilest of her sex, and doomed for the most part, to disease and abject wretchedness, and an early death, appears in every age as the perpetual symbol of degradation and the sinfulness of man. Herself the supreme type of vice, she is ultimately the most efficient guardian of virtue. But for her the unchallenged purity of countless happy homes would be polluted, and not a few who in the pride of their untempted chastity, think of her with an indignant shudder, would have known the agony of remorse and of despair. On that one degraded and ignoble form are concentrated the passions which might have filled the world with shame. She remains, while creeds and civilizations rise and fall, the eternal priestess of humanity, blasted for the sins of the people."

While prostitution may be a necessary evil under our present social system, the experience of the past and the opinions of the best posted men in other nations and in our own country, prove beyond question that many of the resultant evils are not necessary and may, to a great extent, be prevented. As a step in this direction, I would suggest the AMERICAN MEDICAL ASSOCIATION invite the most able and prominent men throughout the country, considered to be the best posted on this and relative subjects, to a conference for the purpose of adopting such measures as, in their judgment, will result in the greatest good to the race and to society. I would ask not only physicians but police and other officials from our great cities, and any one who may be qualified to speak with authority on the subject under discussion.

Personally, I believe it is a mistake to try to, and an impossibility to suppress prostitution by passing laws and imposing penalties, but that society may eliminate and possibly eradicate the vice, by means of education and more careful breeding. I am of the opinion that less than 10 per cent. of the children born are the result of an actual desire for children backed by an intelligent study in an effort to breed and raise the best. This would leave over 90 per cent. born as the result of accident, while following the pursuit of physical pleasure, which must certainly have a great influence on the race and on the problems we are now considering. Out of this 90 per cent., a portion will most surely be born with perverted and abnormal instincts and passions.

A physically perfect man, standing high financially, and occupying a prominent place in society, may have a deformed moral nature which he recognizes and covers up, or, again, he has never thought of nor been educated on sexual relations. He marries a refined and highly-cultured woman. Ordinarily a model man, he occasionally finds some jolly companions, winds up with a big spree, goes home drunk, sick, and filthy, revolting to his wife and family. His wife is horrified and disgusted, and while he insists on his marital rights, she loathes the contact but is compelled to submit. If conception takes place what kind of an individual will be developed? If the mental qualifications be derived from the mother, a sexually cold and passionless being; if from the father, possibly the opposite extreme. If the mother feels that conception has taken place, broods over her troubles, becomes reckless, tries to murder the child before it is born and fails, a graver element is added to the hereditary influences acting on the child.

Prostitution is a very great evil and its suppression would be a desirable thing, but so long as a great majority of the children born are subject to the worst hereditary influences associated with the sexual passion, and the question of how to breed and raise the best is seldom considered, I do not think its suppression possible. An individual is what he is born, plus his environment. The environment may be changed, but the other qualifications, such as stature, etc., are unchangeable, except to a very limited extent; therefore, some individuals are no more to blame for being prostitutes than others are for having red hair, or blue eyes. The enaction of proper laws to control prostitution and restrict the evils arising from it, with the best measures possible in educating the coming generations on these subjects, I believe is the best that can be done at the present time.

Social purity should be one of the ideal aims of society, and I believe its nearest attainment will be found through the means of education. Our medical schools should give more thorough instruction in sexual hygiene and physiology. Medical men can have great influence in moulding public opinion and causing people to give their children proper instruction in sexual matters. In a majority of our homes at present, if a child dares to ask a question pertaining to sexual matters, it is either lied to or deceived, or silenced in such a way that its mind receives a great shock. That all living organisms reproduce themselves is a fact which may be taught a child with plenty of every-day illustrations, without any element of sensuality presenting itself.

I think that the most wofully ignorant of all classes on such subjects are the clergymen and teachers, and as they wield immense influence their education should not be neglected; and unless special attention be given to the leaders of the churches, they will oppose all efforts along this line, because the truth runs counter to their pet prejudice on the subject of morality. While the church influence is unsatisfactory in the extreme, it is so through ignorance and prejudice. To those who will investigate this subject farther and wish positive and definite information, I would suggest a study of Lecky's "History of European Morals"; Sanger's "History of Prostitution"; Wier's "Lust and Religion"; Lydston's "Text-book of Venereal and Sexual Diseases"; and such other books as will suggest themselves in reading these.

Removal of Great Lengths of Intestine.—Blayney (*Dublin Journal of Medical Sciences*, March) reports a case of removal of 8 feet 4½ inches of intestine from a boy, aged 10. He had been run over by a wagon loaded with grain, the wheels passing over the lumbar region while he was lying on his face. Laparotomy was performed seventeen hours after his admission to the hospital and he recovered, but suffers from looseness of the bowels and occasional vomiting, and exhibits also an abnormally great appetite. From an analysis made on thirty-three of his cases in which over one meter of intestine was removed from human subjects, he concludes that where less than 6 feet 6½ inches are removed, intestinal symptoms are, as a rule, absent, but where more, present.

It is quite common in hospital clinics for the operator to lecture to his class while leaning over his work, and, frequently straightening up to address the students, and thus many valuable minutes are lost. A very wise practice is now being introduced in the German clinics. The professor operates, while one of his clinical assistants lectures to the class, or *vice versa*. The operator can thus concentrate his mind on the important task before him. Professor Albert, of Vienna, lectured to the students while his assistant, Ewald, operated. This method is advantageous to both patient and student. But few are endowed with the ability to lecture and operate simultaneously.

An operation should be done with despatch, without the semblance of undue haste or attempt at show, flourish or brilliancy. Such "speed" should be consistent with good conscientious work and the best results. Despatch in surgical operations is often misconstrued as haste and carelessness by jealous rivals. The operator is rapid whose equipment is thorough from his anesthetizer and first assistant to the application of the safety-pin which secures the final turn of the bandage. He accomplishes his object who does not allow his plans to be modified by suggestions from visitors or guests, who is prepared to promptly combat any emergency that may arise, who operates deliberately, who does not drop his instruments on the floor, and who, in picking up an instrument from the tray, does so for a definite purpose. Such an operator knows what he wants two or three stages in advance, and gives his orders accordingly, so that there shall be no loss of time. His assistants are well trained ("team work") and comprehend his wants by a look or gesture, thus avoiding misunderstanding, conflicting orders and collisions.

It is in the saving of the minutes and avoidance of unnecessary delays that the minimum amount of time is consumed in performing the operation. Such methods should constitute "rapid operating."

VENEREAL DISEASE AS A SOCIAL PROBLEM.*

W. C. GATES, M.D.
ROCKLAND, MICH.

When studying medicine I was taught, not only by one but by many, that if I would attain to the greatest degree of success in the profession I must treat every patient who presented, no matter what his social position or standing, age, or other condition, as if he were infected with venereal disease until I had proved to the contrary. At that time I could not fully credit the statement and questioned the observation of the men who made it. I entered practice about ten years ago, in a town with an average population of 500, which for all practical purposes of this paper is an ordinary country village, isolated from the rest of the world and a great distance from any city. There was no house of prostitution in the township, and no public prostitute has existed within its borders since my residence there, but time and experience have convinced me that my teachers were right in their statement.

Syphilis is a terrible disease and is so recognized by the laity, while the great majority regard gonorrhea as a trivial affection. To my mind it is tenfold more terrible than syphilis, while both diseases cause untold suffering to innocent parties, and during my very limited experience I have seen several blind from the disease. The year I entered the town a young man from one of the best families graduated from one of our schools; a few years later, while on a business trip outside, he contracted gonorrhea, was treated and, as he supposed, cured by a frieend who had suffered several times in the same way. Soon after his return home he was married to a young woman whom I remember as a bright, robust, rosy-cheeked schoolgirl. Since then I have treated the man for stricture and his wife for all the evils following a gonorrheal infection of the pelvic organs. She is pale, anemic, a daily sufferer, and spends nearly a week out of each month in bed. Without children, in a beautiful home, she will drag out her life of misery and suffering.

A farmer's daughter, whom I remember as a beautiful schoolgirl, a perfect type of physical strength, two years ago married a man who bragged of the number of times he had contracted gonorrhea. Soon after marriage her troubles began, her strength failed and physical exertion became a source of discomfort and pain until she was unable to do her own housework. A few months ago I operated on her for pelvic peritonitis.

A year ago I knew a man, with a wife and four children, who possessed a good income and a happy comfortable home. He contracted gonorrhea, infected his wife before he knew it, became frightened and used so-called heroic treatment, and is now at Mt. Clemens under treatment for gonorrheal rheumatism, his wife is in a Chicago hospital to undergo an operation for salpingitis, the home is sold to pay the expenses, and the children are cared for by strangers.

I would ask my hearers to lay aside all prejudice and consider this subject in the true scientific spirit, going back to the fundamental underlying principles: 1, the passions actuating those who keep this evil in existence; 2, the breeding of children and the hereditary mental influence to which they are subjected; 3, the want of police and medical supervision through a morbid sentiment and a lack of knowledge in a class which wields the greatest influence.

I will first define a passion as a certain movement of the mind which not only influences, but predominates and controls the entire organism. What is the one supreme passion in man? What is the one supreme passion which actuates and controls, not only man, but all living organisms, without which, if suppressed, all life would soon cease to exist? The answer is plain—the sustenance of life. The passion which ranks next to this and nearly equals it in power is the propagation of life. If either of these passions were suppressed all life would soon cease to exist. They are unchangeable laws of Nature and no arbitrary law of society can suppress them or control them except to a very limited extent. These facts should never be lost to sight. Prostitution finds the reason for its existence in one of these passions, and if society would protect itself from the evils arising from prostitution it must study the subject carefully and act on reason instead of prejudice.

I believe much of the evil can be prevented and, as the acme of medical science is the prevention of disease, that this problem is pre-eminently one for the attention of the Association. It can not be left to the church, as she is unable to cope with it, and her influence, when brought to bear on this subject, has invariably been unsatisfactory. Churchmen are educated along different lines, seldom taught to differentiate fact from theory, or to reason from effect to cause, and they appeal largely to the sympathies and prejudices of those whom they would influence. Frequently, in times past, a few individuals have made a careful study of this phase of social life and succeeded in passing laws in some communities which have greatly mitigated the evils to which I have called attention, but the church has usually succeeded in sweeping them off the books.

* Presented to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Prostitution has existed under every social system of which the world has knowledge. Lecky, in his "History of European Morals," says: "Under these circumstances, there has arisen in society, a figure which is certainly the most mournful, and in some respects the most awful upon which the eye of the moralist can dwell. That unhappy being whose very name is a shame to speak, who counterfeits with a cold heart the transports of affection and submits herself as the passive instrument of lust; who is scorned and insulted as the vilest of her sex, and doomed for the most part, to disease and abject wretchedness, and an early death, appears in every age as the perpetual symbol of degradation and the sinfulness of man. Herself the supreme type of vice, she is ultimately the most efficient guardian of virtue. But for her the unchallenged purity of countless happy homes would be polluted, and not a few who in the pride of their untempted chastity, think of her with an indignant shudder, would have known the agony of remorse and of despair. On that one degraded and ignoble form are concentrated the passions which might have filled the world with shame. She remains, while creeds and civilizations rise and fall, the eternal priestess of humanity, blasted for the sins of the people."

While prostitution may be a necessary evil under our present social system, the experience of the past and the opinions of the best posted men in other nations and in our own country, prove beyond question that many of the resultant evils are not necessary and may, to a great extent, be prevented. As a step in this direction, I would suggest the AMERICAN MEDICAL ASSOCIATION invite the most able and prominent men throughout the country, considered to be the best posted on this and relative subjects, to a conference for the purpose of adopting such measures as, in their judgment, will result in the greatest good to the race and to society. I would ask not only physicians but police and other officials from our great cities, and any one who may be qualified to speak with authority on the subject under discussion.

Personally, I believe it is a mistake to try to, and an impossibility to suppress prostitution by passing laws and imposing penalties, but that society may eliminate and possibly eradicate the vice, by means of education and more careful breeding. I am of the opinion that less than 10 per cent. of the children born are the result of an actual desire for children backed by an intelligent study in an effort to breed and raise the best. This would leave over 90 per cent. born as the result of accident, while following the pursuit of physical pleasure, which must certainly have a great influence on the race and on the problems we are now considering. Out of this 90 per cent., a portion will most surely be born with perverted and abnormal instincts and passions.

A physically perfect man, standing high financially, and occupying a prominent place in society, may have a deformed moral nature which he recognizes and covers up, or, again, he has never thought of nor been educated on sexual relations. He marries a refined and highly-cultured woman. Ordinarily a model man, he occasionally finds some jolly companions, winds up with a big spree, goes home drunk, sick, and filthy, revolting to his wife and family. His wife is horrified and disgusted, and while he insists on his marital rights, she loathes the contact but is compelled to submit. If conception takes place what kind of an individual will be developed? If the mental qualifications be derived from the mother, a sexually cold and passionless being; if from the father, possibly the opposite extreme. If the mother feels that conception has taken place, broods over her troubles, becomes reckless, tries to murder the child before it is born and fails, a graver element is added to the hereditary influences acting on the child.

Prostitution is a very great evil and its suppression would be a desirable thing, but so long as a great majority of the children born are subject to the worst hereditary influences associated with the sexual passion, and the question of how to breed and raise the best is seldom considered, I do not think its suppression possible. An individual is what he is born, plus his environment. The environment may be changed, but the other qualifications, such as stature, etc., are unchangeable, except to a very limited extent; therefore, some individuals are no more to blame for being prostitutes than others are for having red hair, or blue eyes. The enaction of proper laws to control prostitution and restrict the evils arising from it, with the best measures possible in educating the coming generations on these subjects, I believe is the best that can be done at the present time.

Social purity should be one of the ideal aims of society, and I believe its nearest attainment will be found through the means of education. Our medical schools should give more thorough instruction in sexual hygiene and physiology. Medical men can have great influence in moulding public opinion and causing people to give their children proper instruction in sexual matters. In a majority of our homes at present, if a child dares to ask a question pertaining to sexual matters, it is either lied to or deceived, or silenced in such a way that its mind receives a great shock. That all living organisms reproduce themselves is a fact which may be taught a child with plenty of every-day illustrations, without any element of sensuality presenting itself.

I think that the most wofully ignorant of all classes on such subjects are the clergymen and teachers, and as they wield immense influence their education should not be neglected; and unless special attention be given to the leaders of the churches, they will oppose all efforts along this line, because the truth runs counter to their pet prejudice on the subject of morality. While the church influence is unsatisfactory in the extreme, it is so through ignorance and prejudice. To those who will investigate this subject farther and wish positive and definite information, I would suggest a study of Lecky's "History of European Morals"; Sanger's "History of Prostitution"; Wier's "Lust and Religion"; Lydston's "Text-book of Venereal and Sexual Diseases"; and such other books as will suggest themselves in reading these.

Removal of Great Lengths of Intestine.—Blayney (*Dublin Journal of Medical Sciences*, March) reports a case of removal of 8 feet 4½ inches of intestine from a boy, aged 10. He had been run over by a wagon loaded with grain, the wheels passing over the lumbar region while he was lying on his face. Laparotomy was performed seventeen hours after his admission to the hospital and he recovered, but suffers from looseness of the bowels and occasional vomiting, and exhibits also an abnormally great appetite. From an analysis made on thirty-three of his cases in which over one meter of intestine was removed from human subjects, he concludes that where less than 6 feet 6½ inches are removed, intestinal symptoms are, as a rule, absent, but where more, present.

CIRCUMCISION IN RESTRICTING THE SPREAD OF SYPHILIS.*

HAROLD N. MOYER, M.D.
CHICAGO.

There is difference of opinion as to the mortality of the chief venereal diseases, syphilis and gonorrhea. The latter was, until quite recently, regarded as purely local, but after the gonococcus was identified and cultivated, it was found that general infections were frequently caused by this organism. Pleurisy, meningitis, myocarditis and peritonitis, and of late a gonococcemia have all been indentified. These considerations force the conclusion that gonorrhea is not the innocent local disease it was formerly thought to be, with complications largely of a mechanical nature, such as stricture, etc. There will probably be a widening conception of the disease-producing power of the gonococcus, since it has been recognized that, in common with other germs, its pathogenic power depends upon a toxin and not upon the germ itself. The observations of Young show that in many cases the gonococcus can be identified by cultivation when it has escaped detection by centrifugalizing fluids, spreading and staining.

Hyde and Montgomery, in their work on venereal disease, say that gonorrhea and its complications have a mortality greater than syphilis. We are quite sure that the neurologist will deny this. As a matter of fact, neither is in a position to judge the mortality of these affections in their true light. To the andrologist comes those complications of the genito-urinary tract with ascending infection of the urinary tract. These form a group that leads him to think that gonorrhea is one of the most deadly diseases that affects the human race. The acute cases that are cured and have no relapse, in his own practice as well as in that of others, do not return, and, hence, his experience largely deals with cases having severe and lasting complications. The neurologist, looking over his case books, finds the enormous incidence of syphilis in grave disorders of the nervous system, and comes to the conclusion that syphilis is one of the most deadly affections of the human race. The large number of cases that escape involvement of the nervous system do not come under his observation. The same thing is true of the operating gynecologist, who largely fails to see those cases which are not infrequent in practice, in which the gonococcal infection is followed by a comparatively slight reaction in the urethra or the vagina, and subsides without involving the tubes or the endometrium.

It is not profitable to argue as to the comparative deadliness of these two infections, when they are both responsible for so much preventable suffering. Their legal restriction has been attempted in other countries, and legislation has been proposed and at times initiated in this country, looking to a restriction of the venereal diseases. It is proposed to effect a sort of quarantine against infected individuals, giving the health authorities plenary jurisdiction in such cases. The system of inspection of houses of prostitution in continental cities and registration has been revolting to the Anglo-Saxon, and its efficacy in restricting the spread of gonorrhea is doubtful. An infected person may convey gonorrhea long after all local signs have disappeared, and even after microscopic examinations of the secretions fail to show the gonococcus. Hence mere inspection is of little value, while microscopic examination of [illegible] is impracticable because of the time required. Cultures would identify the germ if present, but these consume more time than the ordinary spread and stain. In restricting the spread of syphilis, inspection would be of value.

While the profession is studying the restriction of venereal diseases, I would especially call its attention to the literature bearing on circumcision. This operation is known to enormously lessen the case incidence of syphilis. It is free from risk, and does not inflict any disability on the individual; on the contrary, the operation is a decided gain, even if it had no influence in directly lessening the venereal diseases. It does away with phimosis, balanitis, and tends to prevent hernia and rectal prolapse, as well as a frequent train of nervous symptoms which follow a constricted and adherent prepuce.

A comparison of the condition of the glans and the preputial fold in those who have been circumcised and those who have not, reveals a striking difference. In the uncircumcised the ducts at the frenum become clogged with secretions, the mucous membrane of the glans is sodden and easily excoriated. Once a solution of continuity is formed in the epithelium, the retained secretions form an admirable culture-medium. It is surprising how few statistics there are bearing on this subject, but those that are at hand conclusively confirm the immense importance of circumcision in preventing the spread of syphilis. Jonathan Hutchinson[1] gives the following table showing the incidence of syphilis and gonorrhea in a series of hospital cases, one-third of whom were Jews.

	Total Venereal Cases.	Gonorrhea.	Syphilis.
Not Jews	272	107	165
Jews	58	47	11

Freeland[2] speaks of his experience with the Peninsular and Oriental Steam Navigation Company, as ship surgeon. He never remembers having seen a primary syphilitic chancre among the Lascar crews, who were invariably circumcised, while venereal diseases other than chancre were very common among the circumcised. He gives the following table to show the relative frequency with which primary infection occurs on the prepuce:

	No. of Initial Lesions.	No. on Prepuce and Furrow.	Percentage on Prepuce and Furrow.
Fournier	423	314	74.2
Clerc	325	234	71.6
Berkeley Hill	150	111	74.0

Perhaps it is too much to say that all of the 73 per cent. of cases which occur on the prepuce and in the furrow would be prevented by circumcision, but certainly a large proportion of them would, and the enormous reduction, even if it were estimated at 50 per cent., would so far lessen the case incidence of syphilis and the reduction of hereditary and accidental infections, as to make the universal adoption of this operation one of the leading hygienic factors in improving the physical condition of the race. It may be argued that there is some fallacy in these figures. In a recent number of the *Journal of Mental Science*,[3] it is stated that the proportion of general paralytics among the Jewish population of the London asylums is much larger than in other races. If we assume that syphilis is the chief factor in the production of general paralysis, we may well ask ourselves why, if this infection is less common among Jews, general paralysis should be more frequent?

Read before the Physicians Club, Chicago.

[1] Freeland: The Lancet, Dec. 29, 1900.
[2] Ibid.
[3] *October, 1900, vol. xlvi, No. 195.*

Several arguments might be advanced in support of the view that syphilitic infection is less common among Jews, and, at the same time, general paralysis is more frequent. It may be that those exciting factors that play such an important rôle in the production of general paralysis are relatively very frequent among the Jews A further possibility is that other forms of insanity are comparatively rare, thus reducing the total Jewish population of the asylums, but relatively increasing the number of paretics. In view of these possibilities, the argument loses its effect as against the prophylactic value of circumcision in preventing the spread of syphilis.

Many in our profession, realizing the disastrous effects of syphilis, have earnestly advocated the legal regulation of prostitution. In view of the doubtful efficacy of registration and examination, I would earnestly invite their attention to the figures contained in this paper. It is an operation that is simple, devoid of mortality or disfigurement, against which nothing can be said, and which has as a result, if universally applied, a lessening of the most disastrous of venereal diseases from 50 to 75 per cent. I earnestly hope that they will give attention to this matter, and throw the weight of their authority in favor of the operation. It is a practical means of reform, ready to hand, and its application is within the reach of every physician.

REPORT OF THE SPECIAL COMMITTEE OF THE SECTION ON STATE MEDICINE OF THE AMERICAN MEDICAL ASSOCIATION.

APPOINTED TO INQUIRE WHETHER AND WHEN THE GONORRHEIC MAY BE PERMITTED TO MARRY, AND WHETHER THE MATTER IS A PROPER ONE FOR REGULATION BY STATUTE.

The resolutions under which your Committee was appointed directed the following inquiry: 1. Whether the *gonorrheic* can be so treated and so far cured that he can be allowed to marry with safety to his wife. 2. If he can be so cured, what are the forms of treatment best calculated to cure, the period of time which should elapse and the physiologic reactions which will positively determine the question of his fitness?

QUESTIONS SENT TO GYNECOLOGISTS.

To the gynecologists who more than any others deal with the remoter and more serious results of the disease, the following list of questions was submitted: 1. What proportion of the cases of pelvic inflammation coming under your care are attributable to gonococcal infection? 2. In what proportion of these cases, if any, has infection resulted where the man had been pronounced cured by a competent physician after thorough treatment and careful bacteriologic examination? 3. In what proportion of cases in the female is gonorrhea curable so that the patient is no longer infectious? 4. In what proportion of cases is sterility traceable to gonorrheal infection?

Drs. P. D. Jacobs, of Brussells; S. Pozzi, of Paris; Prof. V. Czerny, of Heidelberg; Drs. Heywood Smith and Granville Bantock, of London; E. H. Grandin, H. J. Boldt, P. Sherwood Dunn and Paul F. Mundé, of New York; A. J. C. Skene, of Brooklyn; Barton C. Hirst, Charles P. Noble, J. M. Baldy and Joseph Price, of Philadelphia; J. W. Bovée, J. S. Stone and H. L. E. Johnson, of Washington; Ely Van de Warker, of Syracuse; W. D. Mann and C. C. Frederick, of Buffalo; J. F. Baldwin and F. F. Lawrence, of Columbus; W. H. Wathen, of Louisville; Hunter Robb and W. H. Humiston, of Cleveland; Joseph Eastman, of Indianapolis; Henry T. Byford and E. C. Dudley, of Chicago; A. Lapthorn Smith, of Montreal; James A. L. Ross, of Toronto; Emory Lanphear, of St. Louis, and H. Kreutzmann, of San Francisco, replied by letter, and by reprint, Dr. Reuben Peterson, of Grand Rapids. A reply from one New York gynecologist came unsigned, and while your Committee tabulated his returns, they have not been able to satisfy themselves of his identity.

Drs. Abraham Dudley, of New York; Henry O. Marcy, of Boston; E. E. Montgomery, of Philadelphia, and Professor Leopold, of Dresden, acknowledged the receipt of the questions, but excused answering them on the ground of the press of other work. Dr. Marcus Rosenwasser, of Cleveland, in a letter, in which he stated that he had so far kept no tabulated record along the lines of the inquiry suggested by the Committee, made the suggestion that gynecologists keep an especial record for one, two or three years from now on with a view of answering such questions, the diagnosis in each case to be corroborated by microscopic or bacteriologic test, concluding that a collective report along such lines would, in his judgment, furnish data from which approximate conclusions could safely be drawn.

QUESTIONS SENT TO GENITO-URINARY SPECIALISTS.

To the genito-urinary specialists the following list of questions was sent: 1. Is gonorrhea curable—so curable that the physician can confidently say to his patient: "You may marry now. You run no risk of infecting your wife?" 2. In what proportion of cases is it so curable: *a*, in anterior urethritis; *b*, in posterior urethritis? 3. What methods of treatment in your experience give the most prompt and certain results: *a*, in acute cases; *b*, in chronic cases? 4. What period of time should elapse after the disappearance of the last evidence of the presence of the gonococcus before the patient should be allowed to marry? 5. Upon what tests do you rely in order to determine positively whether the patient is wholly free from the gonococcus and is no longer infectious?

Replies have been received from Professors A. Neisser, of Breslau; E. Fuerbringer, of Berlin; H. Feleki, of Budapest; N. Jadassohn, of Berne; E. Burkhardt, of Basel; E. Finger, of Vienna; S. Rona, of Budapest, and P. Tommasoli, of Palermo; Drs. J. Verhoogen, of Brussels; J. de Keersmaecker, of Antwerp; Charles Audry, of Toulouse; A. Guepin, and P. Nogues, of Paris; Charles W. Cathcart, of Edinburgh; Gardner Allen, of Boston; Eugene Fuller, Herman Klotz, James P. Tuttle, Edward L. Keyes, Charles H. Chetwood, Ramon Guitèras, and George E. Brewer, of New York; H. M. Christian, William White and Edward Martin, of Philadelphia; Roswell Park, of Buffalo; William T. Corlett, of Cleveland; William Judkins and A. Ravogli, of Cincinnati; G. Frank Lydston, Joseph Zeisler and W. T. Belfield, of Chicago; C. E. Burnett and Bradsford Lewis, of St. Louis, and George Chismore, of San Francisco. Drs. Max Melchior, of Copenhagen, and Orville Horwitz, of Philadelphia, replied by reprints.

EFFECTS OF GONORRHEA ON THE FEMALE.

The portion of the work assigned to Dr. Dickinson was greatly delayed by her necessary absence abroad, and the returns have come in only partially, and not in time for anything like complete collation. The questions submitted were as follows: What are the effects of gonorrhea on the female? 1. Are the vulvovaginal and periurethral glands infected? 2. Are the urethra, bladder, ureters and kidneys infected? 3. Is the rectum infected 4. Is the myometrium infected, cervical and corporeal? 5. Is the endometrium infected, cervical and corporeal? 6. Is the endosalpinx infected? 7. Is the pelvic peritoneum infected? 8. Are the lymphatic vessels and glands which drain the genitals and rectum infected? 9. Is there any affection of the joints single or multiple? 10. What are the other effects? 11. Should gonorrhea be recognized by statute and, if so, what should be the substance of the law?

The answers to questions 1 to 10, inclusive, are simply corroborative of the answers to the questions submitted by the chairman to the gynecologists. Most simply answer "yes," but Winslow Anderson, of San Francisco, gives his reply in percentages, as follows: 1. The vulvo-vaginal glands and Skene's glands of the urethra are infected in fully 75 per cent. of my cases. 2. The urethra is infected in about 40 per cent., the bladder in 10 per cent., the ureters and kidneys in about 2 per cent. 3. The rectum is infected in about 2 per cent. (Lydston, and one other who forgot to sign his name, qualify by stating that this occurs only in perverts where coitus is practised per rectum.) 4. The myometrium, cervical and corporeal is infected in about 50 per cent. of cases. 5. The endometrium, cervical and corporeal is infected in about 90 per cent. of untreated cases. 6. The endosalpinx is infected in about 25 per cent. of untreated cases. 7. The pelvic peritoneum is infected in about 25 per cent. of untreated cases. 8. The lymphatics are infected in 25 per cent. 9. The joints are infected in from 1 to 2 per cent. of my cases. 10. The other effects are septic absorption, which destroys the red blood-corpuscles, causing leukemia, and septic anemia with deterioration of the red blood-corpuscles and hemoglobin. (Newman adds: "Sterility, ophthalmia neonatorum, etc."; Canney, "sterility, endometritis"; Harsha, "sterility more or less permanent, endocarditis, fixation of uterus and adnexa, etc."; Orendorf, "invalidism and sterility"; Burr, "endocarditis"; Matos, "all the serosæ, pleura, peritoneum, meninges, etc."; Steele, "resulting sterility and relapsing invalidism," and Kales, "perioöphoritis as well as the conjunctiva of the patient herself or her new-born child if she has one. The latter infections I hold to be of considerable medicolegal importance.")

VIEWS OF THE GYNECOLOGISTS.

1. *Pelvic Inflammation and Gonococcal Infection.*—In reply to the question as to the percentage of pelvic inflammation traceable to gonococcal infection, there seems to be a very wide diversity of opinion among gynecologists. The widest is between Van de Warker, who in forty years has seen but two cases where gonorrhea invaded the tubes; Bantock,[1] who sees no reason to change his views expressed in a paper read before the Section of Obstetrics, Medicine and Gynecology, at the annual meeting of the British Medical Association, in Birmingham, July, 1890; Cathcart, who, after 4½ years' work in the Lock wards of the Edinburgh Royal Infirmary, maintains that "the majority of those who have suffered from disturbances of the menstrual function have not been affected more severely than one expects to find in a similar number of women who lead regular lives," although he admits that "there certainly have been a few cases of undoubted salpingitis and ovaritis"; and Humiston, who finds that, "without classifying doubtful cases as gonorrhea, 90 per cent., at least, of pelvic inflammatory troubles are attributable to gonorrhea, the infection being usually of a mixed character—gonococcal with some one of the pyogenic micrococci," and Joseph Price, who says that in over one thousand sections for pelvic suppuration, 90 per cent. were traceable to gonorrheal infection, and that 90 per cent. of those histories are reliable and clear. Czerny regards it as impossible to tell. Boldt estimates from 5 to 8 per cent., admitting it a guess. Ten per cent. is the estimate of Skene, Robb, Eastman and Bovée. Dunn gives the same percentage for private cases, and Jacobs—5000 private cases—gives 10 to 12 per cent. Johnson says "a large majority"; Wathen, "nearly all of the cases"; Byford, "in majority," and Mann, "nearly all" of those who have not borne children; Heywood Smith, differing from his English confrères, finds many cases of salpingitis and ovaritis due to gonococcal infection, and Barton Hirst also finds the number large. The estimate of Pozzi and Frederick is 75 per cent.; 60 per cent., that of Lapthorn Smith and Stone; 50 to 75 per cent., the estimate of Baldwin; 50 per cent., that of Watkins and Lawrence; Ross, 30 per cent., omitting sepsis following labor, and Noble, while giving 50 per cent. as his estimate, is under the impression that it is too low. Dunn finds 33 to 55 per cent. in charity hospital work; Lanphear, not to exceed 25 per cent., excluding prostitutes; Kreutzmann, at least 33 per cent.; Baldy, 33 per cent.; Grandin, 20 per cent.; Jacobs—7000 cases—18 per cent., in polyclinic cases. E. C. Dudley, while giving no estimate as to percentage, has found not infrequently the gonococci in the tubes removed.

Diverse as these estimates are, the weight of evidence bears unmistakably toward the conclusion that gonococcal infection is a very considerable factor in the causation of the inflammatory diseases of the pelvic organs in the female, and that, as Peterson aptly remarks,[2] "the more the disease is studied in women, and the greater the improvements in bacteriology, the higher is to be found this percentage."

2. *Infection from Patients Pronounced Cured.*—As to the second question regarding infection by men where the cases had been pronounced cured after thorough treatment and careful bacteriologic examination, a large majority responded that they have no data. Baldwin knows of but few instances where such examination has been made, but one such was followed by prompt infection. Mann knows of but two cases; Jacobs gives 2 to 5 per cent.; Eastman, 5 per cent.; Noble recalls three cases; Hirst has seen it recur a number of years after the man was pronounced cured. E. C. Dudley does not estimate the proportion, but states that many wives of such men have salpingitis. The gonococcus is not uniformly found; it may never have been present, or other germs may have taken its place. Wathen states that many are so infected, but that physicians seldom make correct examinations, hence their opinions are not reliable. Byford finds the infection usually from recent cases or complicated old ones. Lanphear has known a large number of infections where the man has not waited long enough, and where no bacteriologic test had been made. Humiston, while giving no estimate, inquires, very pertinently: "How many physicians do make careful bacteriological examinations?" Price says: "In a large percentage—over 50 per cent., in married women"; Lawrence, "Very difficult to determine, but probably about 20 per cent." Jadassohn states that when, after thorough treatment and repeated and thorough bacteriologic examinations, he has concluded that a *man* is cured *and, as he has often done, has* permitted marriage, he has never come to know of a single infection that has taken place following the marriage. Finger, likewise says: "With a very extensive" —genito-urinary— "*practice and numerous candidates for marriage* I have, as yet, seen no case where a person, permitted to marry as cured, has infected his wife." Frederick says: "I do not know that I have ever known of infection after thorough treatment and the culture tests have been negative; most men, as you know, are pronounced cured when the discharge ceases. If your report can in any way lead the general profession to more fully realize the injustice they are doing by their careless and incomplete treatment of these cases and by the consent to marriage and to intercourse, not having proven that the man is cured, you will merit the praise of all womenkind."

3. *Curability of Gonorrhea in the Female.*—As to the curability of gonorrhea in the female, so that the patient is no longer infectious, there is also a wide diversity of opinion. Johnson says the proportion is very small—"once a clap, always a clap"; Bovée, 5 per cent.; Lapthorn Smith thinks that none are absolutely curable, but in the course of time the infection dies out—the gonococcus kills itself with its ptomains —in all cases. Frederick says: "I have never seen one whom I felt sure was absolutely cured; if we could know all the subsequent history of women after we had treated them we might find that some were cured. I have known men to be infected by women whom I had treated thoroughly and for a long period, thinking them cured. Some men in a sense become immune to gonorrhea. I have known a man to cohabit with a woman for years without infection, and another was infected at the first intercourse with this same woman." Noble regards it as a matter of great difficulty to positively eradicate gonorrhea in the female. Pozzi regards it as "very often" curable. Dunn says: "Where the gonococcus has not invaded the tubes they are all curable." Skene regards all cases as curable where the disease has not reached the body of the uterus and oviducts. Lawrence says: "All if proper treatment be instituted early." Byford considers nearly all as curable "after a long time." Ross says: "No reason to believe that there are any incurable cases in this sense so far as danger of infection of the male goes. While the disease may spread up into the tubes and ovaries and may produce incurable disease in these I am firmly convinced that the vagina remains no longer infectious." This is corroborated by E. C. Dudley, who says: "Many widows who have had gonorrhea from the first husband fail to infect the second husband. I do not recall a case in which a man was infected in consequence of marriage with a widow. If the danger were very great I think more men would suffer. Why should not a man marrying such a widow be as liable as a woman marrying a man with a gonorrheal record?" Watkins believes that nearly all cases are curable "if treated early, actively and especially during the first one or two mentrual periods following the infection"; Wathen, "in nearly every case"; Baldy, "100 per cent." Van de Warker has always found the duration of the disease short and more tractable in women than in men, while Hirst thinks "gonorrhea is apt to remain latent in the female and to be infectious for a long time." Boldt says, "it is curable in nearly all cases and I believe in all if thoroughly and patiently cared for." Grandin states "that if seen in the acute stage, e. g., after infection of uterus, cure doubtful." Robb believes "that all cases if properly treated and if kept under the observation of a competent physician can be cured." Kreutzmann regards it "absolutely curable either with conservative treatment or *radical operative procedures.*" *Humiston's opinion* is that "every female can be freed from gonorrheal infection by proper procedures, the vagina and uterus readily, the Fallopian tubes and the Bartholini glands may require complete extirpation." Price says: "Incurable if the diseased uterus and appendages remain. Infection rarely occurs after prolonged treatment of vagina and mucous membrane," and Jacobs concludes as follows: "In the vagina gonorrhea is easily curable, in the cervix with difficulty, in the uterus and peritoneum, incurable except by radical operation." It is Audry's opinion that "in a general way in the case of a woman one can express a great probability in favor of a cure, but one never has a certainty thereof; for the duration may be indefinite, the latency absolute, and the infection manifest quite formidable habits of reviviscence."

4. *Gonorrheal Infection and Sterility.*—As to the extent to which sterility is due to gonococcal infection, Pozzi

says: "It is impossible to say"; Van de Warker states that "the results of an investigation once carried on were negative." Of those giving percentages, Dunn's estimate is the lowest, viz., 3 per cent.: A. Lapthorn Smith estimates 12 per cent. due to the man's gonorrhea, and 21 per cent. due to the wife's. Jacobs gives from 20 to 21 per cent.; Skene, Grandin and Boldt estimate 33 per cent.; Bovée, 40 per cent., as also does Ross; Stone, Lanphear, Price, Frederick and Mann give 50 per cent.; Noble, 66 per cent.; Eastman and Baldwin, 75 per cent.; E. C. Dudley, Byford, Johnson, Watkins, Wathen, Boldt and Heywood Smith, without giving any definite percentages, regard the number as very large. Hirst and Robb regards it as the rule where infection has occurred. Humiston and Kreutzmann say that sterility results in every case where ovaries or tubes are attacked, and Czerny believes that "certainly in half the cases the sterility of the woman is to be traced to the husband's gonorrhea."

VIEWS OF THE GENITO-URINARY SPECIALISTS.

1. *Curableness of Gonorrhea.*—As to the first question propounded to the genito-urinary surgeons, viz., whether gonorrhea is so curable that the physician can confidently say to his patient: "You may marry now, you run no risk of infecting your wife," they have without exception responded "Yes." Some of them, however, qualified their answers to a certain degree as follows:

Lydston said: "In the majority of cases"; Chismore, Fuller and Verhoogen, "In the great majority"; Park, "In the majority of cases if the disease is not too extensive"; Ravogli, "If organs which can not be reached by instruments be not involved"; Zeisler, "That depends on a variety of conditions which are not always controllable by the physician"; Allen, "But we can not certainly predict recovery at the outset in any given case"; Audry, "If the physician attends to it diligently and the patient is willing to care for himself as required and for as long a time as is necessary"; Feleki, "Only a small percentage must, in consequence of the uncertainty of the duration of their infectiousness, or in consequence of serious complications, be looked upon as incurable. I estimate this proportion as about 3 per cent."; Guepin, "Gonorrhea (gonococcal urethritis) is curable, but not more so than syphilis, and like it, the physician can never say to his patient that he is absolutely cured"; Jadassohn, "Not curable in such a sense that the physician can indeed undertake to guarantee that no infection will result therefrom, but so that in good conscience he can give an assurance that in all human probability infection is now excluded."

2. *Curableness of Urethritis.*—With regard to the second question, the relative curability of anterior and of posterior urethritis, there is considerable diversity of opinion as to the exact percentage, but a general agreement as to the curability of a great majority provided proper treatment be instituted early and persisted in until the evidence of cure is complete. Finger states that "all are curable." "I have," he says, "as yet seen in my practice no condition in which, with earnest determination on the part of the patient, it has not been possible to bring about a cure." But he also says, "I always follow this principle rigidly; when a patient does not obey my injunctions and take the treatment of the disease seriously; when warnings do not bear fruit, I positively decline to treat him further." Keyes and Chetwood, Belfield, Lydston, Chismore, De Keersmaecker and Audry maintain that practically all cases are curable in so far as infectiousness of the man is concerned, it being understood that time enough is allowed to effect a cure. Fuller expects all to be cured except where tuberculosis or extensive involvement of glands coexist. Burnett says, "100 per cent., if gonorrhea alone be present"; White, "Nearly all"; Martin, "95 per cent. certainly"; Judkins, "85 per cent., but somewhat less in posterior urethritis." All cases of anterior urethritis are regarded as curable by Guitêras, Christian and Tuttle. Klotz regards posterior urethritis not less amenable than anterior, provided the deeper glandular appendages or adnexed organs be not involved; in a large majority of cases both are curable; likewise Allen notes a large majority as recovering, but more in cases of anterior than in posterior urethritis. Feleki finds 2 to 3 in 1000 of anterior urethritis incurable, and from 26 to 28 in 1000 of posterior urethritis. Rona says: "The majority of uncomplicated cases of total as well as anterior urethritis": Verhoogen, "Anterior urethritis always curable, posterior urethritis with greater difficulty." Neisser gives a good prognosis in anterior urethritis, a less favorable one in posterior. Burkhardt says he sees no acute cases whatever, but in 256 cases of chronic urethritis—all of posterior or total urethritis—reports 245 complete cures. Christian regards a small proportion of chronic posterior urethritis as incurable owing to the involvement of the seminal vesicles and prostate. Guitêras estimates 98 per cent.; Cathcart regards it as most obstinate; Tuttle and Corlett estimate 60 per cent., while the latter estimates 80 per cent. in anterior urethritis. Lewis gives from 80 to 90 per cent. of both, provided that there be no serious complications, but he believes that posterior urethritis is present in the great majority of cases of prolonged gonorrhea, and that it is not properly to be considered a complication, but a natural phenomenon of gonorrhea. Tommasoli gives 93 per cent. in anterior, 80 per cent. in posterior urethritis; Zeissler and Fuerbringer give the lowest estimate, the former holding that a majority are cured in anterior, and a minority in posterior urethritis, and the latter giving 50 per cent., and far below 50 per cent., respectively, as his estimate. Jadassohn, speaking of these complicated cases, says: "I personally know of no case where that"—the disappearance of the gonococci—"has not been accomplished, where the patient has not prematurely and arbitrarily interrupted the treatment."

There is no uncertainty therefore in the statement of these physicians, the weight of testimony is unquestionably in favor of the position which has heretofore been publicly taken by one member of your committee, viz., that gonorrhea is a curable disease, curable in every stage, and in a large majority of cases, provided only that the physician exercises due diligence and skill, and the patient cheerfully submit himself to treatment and for a sufficient length of time.

3. *Treatment.*—It is not possible, within the limits of this report, to do even scant justice to the various and accurate details regarding treatment given by your correspondents, some of whom have furnished your Committee with very carefully prepared and full papers. Suffice it to say that broadly speaking they may be divided into two classes: those who employ the Janet method in one or another of its modifications, and those who do not. Whether they employ it or not, these diverse schools of genito-urinary therapeutics all agree upon one point, viz., that the disease is curable if treated patiently, intelligently and persistently, adapting the means to the pathologic condition of the urethra and its adnexa, and to the constitutional idiosyncrasies of the patient. Finger "can not recommend Janet's method of irrigation," but recalls no case of failure to cure. Feleki, who in the very earliest stage uses the urethroscope and through it pencils the affected part and afterward the entire anterior portion of the urethra with a 3 per cent. solution of nitrate of silver, recalls only two or three failures in a thousand in the anterior urethra: Jadassohn, who says that "irrigations . . . without catheters according to Janet's method seem to afford no special advantages, on the contrary often occasion increase of irritation," further says, "the duration of the treatment seems to me the chief factor in all cases and especially those chronic cases in which the tendency is to relapse whenever the treatment is suspended."

On the other hand, Nogues, De Keersmaecker and Verhoogen, claiming the same results as to final cure, are enthusiastic advocates of free lavage with permanganate of potash in the acute stage. All agree that the involvement of the glands of Littre, of Cowper, of the prostate, and of the seminal vesicles, constitute complications requiring especial, prolonged and patient treatment with injections, sounds, dilatations, massage, internal urethrotomy, or even, in some cases, external urethrotomy to effect a cure.

4. *Duration of Gonorrhea.*—As to the question of time limit, Martin, Park, Czerny, Chismore, Fuller, Lydston, Nogues and Corlett mention one year as the proper interval after disappearance of the last gonococcus. Fuerbringer says several months. Six months is Cathcart's limit. Three to six months is the time stated by White, Judkins and Burkhardt. Christian says four to six months; Lewis, three to four; Guitêras, Allen, Jadassohn and Rona, three months. Six weeks to six months from the time the urethral mucous membrane is normal is Burnett's rule. Ravogli prescribes four to six weeks. Guepin's opinion is: "The longer the better." Audry directs three or four weeks in ordinary cases; if, however, there be a slight secretion of the urethra, but without pus, he extends this period to six or seven weeks, but in case the urethritis shows a well-marked purulent secretion, although gonococci have positively disappeared, he requires a period of several months or more, "that is, a lapse of time indefinite, if not infinite." Feleki sets no time limit, but is governed by the absence of pus cells. Tommasoli mentions two to three weeks. De Keersmaecker and Verhoogen judge by the absence of all signs after the usual tests, and Neisser regards the time as a secondary consideration to the fact of demonstrated presence or absence of the gonococcus.

5. *Determination of Cure.*—There is a substantial unanimity in the replies respecting the tests necessary to determine the question whether the patient is no longer infectious. All agree that the examination should be searching, thorough and repeated; that the discharge of the anterior urethra, the posterior urethra, the prostatic secretion and that of the seminal vesicles should be examined separately, and that only on the basis of repeated negative examinations, conducted over a considerable period of time, should the conclusion be reached that the patient is no longer infectious. Jadassohn, however, does not regard beer test and the cohabitation test as necessary to an accurate result, while Cathcart would not recommend illicit intercourse, not considering it justifiable under any circumstances. Most all insist on the absence of pus cells as well as of gonococci. Nogues, Guepin, Feleki, Tommasoli and Lydston in particular call attention to the importance of other pyogenic germs. "The fact is," says Feleki, "that we see cases where men in whom the gonorrhea, from the standpoint of the gonococcus, can be pronounced as positively cured, infect their wives, where nevertheless neither in the man nor in the woman can gonococci subsequently be demonstrated," and further, he says, in regard to such cases, "I hold it as out of the question for the patient to infect his wife with gonorrhea, but in the presence of secretion containing pus, I regard it as possible that the wife can acquire from this husband an infection which is not gonorrheal in character." Nogues says: "Microscopically I do not go so far as to require the absence, in toto, of leucocytes—a thing which is practically impossible, but it ought to be so that they are found only occasionally, and that they be not accompanied by altered epithelium. I must repeat this, that I require the absolute asepsis of this drop"—the "morning drop"—"but I attach a very great importance to this also, that the state of asepsis has not been disturbed by a single attack of secondary infection for a very long time—a year at least." Lydston says: "A patient is dangerous so long as a trace of purulent discharge is present whether the gonococci be present or not; it may not convey gonorrhea, but it is capable of producing non-specific inflammation in a healthy woman which may at any time cause serious pelvic results." Tommasoli is the only one who does not insist on following out these prolonged tests to determine, as positively as can be, the absence of the gonococcus. His reasons are: "1, because bacteriological examination for the gonococcus in chronic urethritis is too deceptive and not sure; 2, because I recognize that there may also exist infective urethritis, acute or chronic, even without gonococci . . . and I do not believe that it is possible in every country to compel the patient to submit to those repeated, multiplied and tedious trials to which Professor Neisser subjects his patients. In my country, where the vivacity and the impatience of patients is such an extreme item, no specialist, I believe, will be able to follow the rules of the school of Breslau, even though he believe them extremely useful." Guepin maintains that "in order to say that the patient is cured it is absolutely necessary that the urethral discharge shall no longer contain a single pathogenic microbe; that the urinary filaments be no longer purulent, and, *a fortiori*, no longer infected; that the products of the submucous urethral glands (glands of Mery in particular) and submuscular (prostate, seminal vesicles) should be normal; the semen ejaculated should also be examined. That methodical examination done after the patient, cured to all appearances, shall have resumed his customary life, while it is of great prognostic value in the majority of cases, still does not warrant the affirmation that the spontaneous reappearance of gonococci is impossible." Neisser sums up the matter as follows: "We do not to-day possess any test or tests which enable us to declare with positive certainty that the patient is wholly free from the gonococcus. When considered from a practical rather than a purely academical standpoint, however, our present methods of examining and 'testing' the patient are such as to deserve our entire confidence, and when these have been carried out in a thorough, careful and intelligent manner by one skilled in their use. the obtaining of a clear negative result will justify the physician in saying to the patient, 'You may now marry; as far as I am able to judge, you will not infect your wife.'"

GONORRHEA AND THE LAW.

The response to Question 11, of Dr. Dickinson's list, shows a pretty evenly divided sentiment as to whether legal restriction should be attempted or not. Winslow Anderson says: "I look upon the sequelæ of gonorrheal toxemia as the most serious complication with which the gynecologist and abdominal surgeon has to deal and something should be done to check the disease, but those who advocate legal restriction are by no means agreed on the best method." Most of them would have rigid and regular inspection of prostitutes, with license of houses of prostitution according to the European fashion. Ridlon would make the wilful transmission of the infection a criminal offense. Steele, Burr and Orendorf would deny license to marry to persons suffering from gonococcal infection. Newman, with a keen recognition of the complexity of the problem, writes: "Laws should be so framed as to secure ample protection to all innocent persons, both women and their offspring, and should be formulated by a committee composed of representatives of both medical and legal profession." On the other hand, Harsha says: "Impracticable to regulate by statute"; Whery, "No. To do so would lead to blackmailing and many social disasters. It is the medical profession and not the law that should repress it." Matos says: "While the gravity of gonorrheal infection justifies its recognition by law, I do not believe that the time is opportune for legal recognition; the subject must still be left in the hands of the profession and to the gradual education of the people to its importance"; Lydston, "I do not believe any statute bearing on gonorrhea would be practical"; Edmund Andrews writes: "In general terms some useful legislation is possible, at least theoretically, but the well-known impossibility of enforcing a law under our present corrupt civil service which has not a strong, watchful and almost unanimous public sentiment sustaining it, renders a good result practically hopeless at the present time. The often suggested plan of having persons appointed to examine physically all candidates for marriage and to decide on their permission would, in our present defective means of keeping examiners above the reach of bribery, blundering and partiality from other motives, wreck any such statute in five years." And, finally, Kales admirably sums up the reasons that prompt so many earnest and honest men to oppose any statutory regulation of the evil, as follows: "Such a serious variety of infections as those listed and known to be propagated by irregular sexual relations may seem to call for legislative interference, or, at least, regulation. Better no law than one which is not or can not be enforced. Public approbation is necessary to the enforcement of such laws. The legal aspect of the question might be divided into: *a.* Laws dealing with domestic immortality. *b.* Laws relative to public immorality.

a. Perhaps the most important laws would be those which aim to protect the innocent woman, or mother, from infection in her marriage relations with her husband. 1. She may be unfortunate enough to marry a man who has an uncured gonorrhea or syphilis and thus either disease is communicated with all its attendant misery. 2. Or she may receive the infection from her husband in later years owing to his dissolute life.

b. Laws which refer to public immorality or prostitution aim to get at the probable sources of infection. Such laws have been in operation in certain countries for many years. The very general opinion is that they have failed, though enforced with the rigor of European police methods.

The times seem foolishly to call for laws which shall suppress or regulate every evil, and these laws are usually impotent according as they are numerous. Their non-enforcement develops lawlessness, and their irregular enforcement is oftentimes a matter of bribery or blackmail. The evils thus developed by over-legislation are often worse than a continuance of the evil legislated against. I should not add a single new law to the statutes, except to amend those which facilitate divorce, and if venereal disease be transmitted, divorce. damage or other penalty should be obtained without unnecessary delay or publicity. Such hearings might be before a judge, and jury of physicians, or laymen and physicians. As regards laws regulating prostitution, I would have none. The general public needs education on venereal and sexual matters by able physicians. It is rare in family practice that the opportunity to give this advice is not afforded one. Advice of this kind should be wholly personal and private, but such counsel usually spreads in the same personal and private manner from one confidant to another and ultimately does much good. Public advice of this kind simply excites morbid sensibility while a confidential interview does much to enable one to get the better of individual weaknesses with no loss of self-respect."

It must be manifest to any one competent to weigh evidence that a disease which is responsible for so large a proportion of pelvic inflammatory diseases and sterility in women is an ailment which demands our conscientious care and earnest consideration as to the best method of stamping it out. We can not but regard it as one of the more serious diseases that affect humankind—all the more serious in that its graver consequences are usually so remote that the connection between cause and effect has not as yet impressed itself upon the minds of the laity, or even of the medical profession as a whole. Worse yet, the cities teem with advertising quacks and the druggists' shelves are stocked with advertised nostrums that claim to quickly cure this disease so serious in its consequence and so intractable in a considerable proportion of cases. The first duty, then, of the profession in this regard would seem to be to impress the gravity of the disease on the minds of their patients, so far as possible, and, as opportunity offers, on the minds of the public generally. Young men should be taught authoritatively that a man with an uncured gonorrhea is a man dangerous to himself, to his family and to the community; that no acquisition to the "wild oats" period, not even syphilis, is likely to be so fraught with serious results to them and to their families in after life. Whatever may be the outcome of syphilis to the individual, under a proper course of treatment and in a period of time fairly well determined, he may marry with a reasonable prospect of having fairly healthy children, and of not infecting his wife. Moreover, a syphilitic expects to undergo from eighteen months to two and a half years' treatment before he is wholly cured, and submits to it willingly. But with gonorrhea, unless a patient knows by the actual determination of the physician, that the very last gonococcus has been dislodged from his urethra and the glands and organs in connection therewith, he is liable to infect his wife with an inflammation that may cost her her ovaries and tubes, if not her life, and the least penalty that it is likely to entail upon her is hopeless sterility. The sooner these facts are known to young men, and parents, and young women the greater will be the incentive to self-control on the part of young men, the greater will be the reluctance of parents to consent to the marriage of their daughters to men whose characters are not clean, and the more willing will those be who are so unfortunate as to have contracted the disease to submit to the treatment necessary to effect a complete cure.

Your Committee would emphasize the necessity of every physician treating every case of gonorrhea seriously, treating it thoroughly from the beginning, treating it with all the appliances which modern science places at his disposal, and not discharging the patient as cured until every evidence of pyogenic process in the secretions of the urethra or of the adjacent glands has disappeared. The members of the profession should also do their best to enlighten their clientele regarding the serious dangers involved in the use of nostrums prescribed over counters by druggists and *sold from* their shelves and advertised in the newspapers—nostrums which profess to cure this disease rapidly and completely. The fact should be emphasized that the disease is not necessarily nor even probably cured when the visible discharge and the burning have ceased; that just at that time it may be taking on its most insidious, chronic and intractable form; that just at that time, when the discharge has apparently ceased, is the time it is essential to know positively from a competent man whether the cure is apparent or real, whether there be any disease remaining in the deeper urethra, its glands, or the organs connected *therewith*.

Aside from the question, whether or not a physician can be legally required or even allowed to report a case of venereal disease, *it* is doubtful in the minds of your Committee whether any plan of examination of prostitutes or any plan requiring a report to health authorities of cases of gonorrhea occurring *in the* hands of general practitioners and specialists can be *made* practicable. The lesions of syphilis are visible to the naked eye, they are obvious, they can be *inspected*; the gonococcus, however, is microscopic and elusive—so elusive that a person may be infectious and yet half a dozen careful examinations may fail to demonstrate the presence of a single one. While it would be easy enough to demonstrate the infectiousness of a person in the acute *stage*, it is not through cases in the acute stage that infection is chiefly spread, but from cases which suppose themselves well, hence it is that the only hope we have of suppressing the spread of the gonococcus is by cultivating a general intelligence regarding the danger and the insidiousness of the contagion, and by never discharging a patient from our hands as cured until, after the use of all the means that science has placed at our command, we can say positively that in all human probability *he is no* longer infectious. Then, and only then, can consent to his marriage be given.

The thanks of the Committee are due to our colleagues in the profession who have so cordially responded to our questions, and to Drs. William Conrad, E. J. Rose, A. Pasini and A. Ravogli for their kindly aid in the translation of the manuscripts in German, French and Italian.

Respectfully submitted,
L. B. TUCKERMAN, Chairman.

PURULENT OTITIS—ITS TREATMENT AND PREVENTION BY THE FAMILY PHYSICIAN.

H. GRADLE, M.D.
CHICAGO.

The scope of the present paper is defined exactly by its title. It is to present to the practitioner the teaching of modern otology regarding a very important disease, for acute purulent inflammation of the middle ear is so common that the majority of cases, at least among children, are seen by the general practitioner, and not by the specialist. Frequent experience has shown me that the form of *treatment* which progressive otologists have recognized as the best and safest has not yet been adopted by all general practitioners. Yet it is so much simpler than the less efficient methods so often employed or advised by physicians. It is but the application of ordinary surgical principles to purulent inflammation localized *in the* ear. Just as in the preantiseptic days, wounds did heal after a fashion, so in incorrectly treated cases purulent otitis will often heal, but delays and unfortunate accidents are much more common. Many an ear and occasionally a life is lost which a little care on the part of the attending physician would have saved.

The diagnosis of acute purulent otitis is very definite. Sudden earache with some feeling of fulness and moderate deafness leave but little doubt as to the diagnosis. The view of the uniformly reddened drumhead seen through the speculum dispels all doubt. During severe infectious diseases, like measles, scarlet fever and diphtheria, the depressed condition of the patient may mask the onset of the ear symptoms, and it is particularly necessary under these circumstances to watch for them. Some doubt may arise in a given case whether the disease is the ordinary form of purulent inflammation, which surely terminates in perforation of the drumhead with discharge through the meatus, or whether it may not be the milder or abortive variety in which no perforation takes place. The latter form is much less common. As a rule the prognosis can be made within the first day. When the pain lasts continuously, perforation will surely follow. When the pain is intermittent, perhaps only nocturnal, the exudate may disappear without discharge through the drumhead. It is only when the pain has been distinctly intermittent that surgical puncture of the membrana tympani should be deferred. Otherwise the interests of the patient are best served by immediate paracentesis.

The first demand of the patient is usually for relief of the severe pain. The use of the various popular ear drops, tincture of opium in sweet-oil, camphorated oil and a host of others can not be condemned too severely. They are all utterly useless and have no influence on the pain. No form of application is known which can surely stop the earache of purulent otitis. Carbolic acid dissolved in glycerin—10 to 12 per cent. solution—has a slight benumbing influence in some mild instances, but it is not to be depended on. It may perhaps help to avert perforation in the mild form of cases. It can therefore be endorsed as a palliative and perhaps slightly curative agent, all the more so since it sterilizes the skin of the meatus if left in place sufficiently long. External heat in the form of the hot-water bag or the Japanese stove gives slight but grateful relief. Severe pain, however, can only be controlled by opium internally. The speediest way of obtaining relief is immediate paracentesis.

The curative treatment consists in draining the discharge promptly and efficiently and preventing secondary changes. The effusion is present as soon as the disease manifests itself, and the sooner it can escape the quicker the relief and the milder the course. It has not been sufficiently emphasized that the discharge is serous at the start—at least in most instances—and only becomes purulent later on. The more severe cases, and especially those due to streptococcus infection, may seem exceptions to this rule. In some of these instances mentioned the effusion is purulent when it breaks through the drumhead or even when paracentesis is done after thirty-six hours. I am quite in doubt, however, whether an earlier puncture would not have shown a serous fluid even in these apparent exceptions. When proper treatment is begun during the stage of serous discharge, the latter can be prevented from becoming purulent and the disease will then pursue the mildest and shortest course possible. Not only is its duration shortened, but the liability to complications is diminished. Personally I have never seen mastoiditis supervene in a case in which the discharge remained serous.

The change from a serous to a purulent discharge is in some instances due to later secondary (mixed) infection by bacterial invasion through the meatus, as can be shown by bacteriologic analysis. But I believe that this is only a later accident and that primarily the purulency is due to insufficient drainage of the serous discharge. For whenever the discharge is retained in the midde ear until a late spontaneous perforation occurs, perhaps on the third or fourth day, it is almost surely purulent. Experience thus points out three well-defined indications in the treatment, viz., early paracentesis, efficient drainage, absolute asepsis.

Puncturing the drumhead is an easy, safe operation for which every practitioner ought to be prepared. The technical details are found in all text-books on the ear. It must be remembered that it causes a sharp, but transient, pain which can not be diminished by any local anesthetic. Before the operation the meatus should be cleansed by syringing if it contains wax or scales of skin, otherwise this is unnecessary. After spontaneous perforation or paracentesis syringing should be avoided. It is useless at best, and if repeated seems to influence the disease unfavorably. If required in order to obtain a view of the punctured drumhead, it should be done with sterile water and under aseptic precautions.

Before paracentesis the meatus should be sterilized in a reliable way. Watery carbolic acid solution may be left in place for at least three minutes, filling the meatus and the auricle. Carbolic acid dissolved in glycerin is not as active a disinfectant and requires a longer time, but its efficacy is increased by previously moistening the walls of the meatus with water. The same sterilization is required before applying the first dressing after spontaneous perforation. For the purpose of drainage, a narrow strip ($\frac{1}{2}$ by 4 inches) of a good absorbent gauze is pushed with a probe through the disinfected speculum into the meatus until it touches the drumhead. The concavity of the auricle is then packed with bits of gauze until a thick pad is formed. As the discharge is sometimes very copious, a large absorbing cushion is required. It may be retained by a strip of adhesive plaster. The external pad should be replaced when it gets moist, which the properly instructed patient can do himself. The strip in the meatus, however, should only be changed by the surgeon once in one or two days. As it is impossible to assure permanent sterility by asepsis alone, it is best to powder the gauze freely with a mixture of boric and salicylic acids (6 to 1). With sufficient thoroughness a serous discharge can thus be prevented from becoming purulent and the patient be saved considerable discomfort, delay and danger. Even when the treatment is begun too late, when the discharge has assumed a purulent character, it is still the best method to insure the most rapid course under the circumstances. Occasionally it happens, especially with a purulent discharge, that the walls of the meatus get macerated. It is best to omit the salicylic acid in such instances, using only boric acid, and to protect the skin by smearing with an oxid of zinc and lanolin salve after thorough drying.

The prevention of acute otitis consists in attention to those influences which are known as causes or predisposing factors and which the family physician can control. The most important of these is the enlargement of the pharyngeal tonsil, or adenoid vegetations. I have observed with much satisfaction that the profession is getting more and more to recognize the importance of this frequent morbid occurrence, and it is only rarely that I now hear the old vicious advice given to patients, "to wait and outgrow it." Experience has shown in the most positive manner that an enlarged pharyngeal tonsil enormously increases the danger to the ear whenever the child takes scarlet fever, diphtheria or measles or merely acquires an acute nasal catarrh. The family physician should insist, without exception, on the removal of adenoid vegetations whenever they are of sufficient size to produce the easily recognizable symptoms of nocturnal nasal obstruction. The operation is free from risk of any kind and properly done causes very little pain.

A second important influence which often leads to a suppurative otitis is the misuse of the nasal douche. I do not condemn the nasal douche as such. It is a valuable therapeutic method with definite indications. But it should not be advised except for these specific indications, since in other instances it is useless. I do not think that it ought to be recommended by any one not fully familiar with nasal pathology. In spite of numerous warnings by otologists, many physicians are still not fully aware of the dangers of the douche. When water gets into the Eustachian tube a violent otitis is almost sure to follow. Many an ear has been permanently damaged and much needless suffering has been caused by the careless advice to a patient "to syringe out the nose." Worse even than this is the suggestion to snuff up fluids or to pour them into the nose with some spoon-shaped device intended as a substitute for the douche. The different contrivances sold for this purpose have not even the valid excuse which can be claimed for the douche itself. The latter does really remove viscid secretion from the upper part of the nasal cavity, where its presence perpetuates disease. The substitutes do not accomplish this at all, but carry with them all the danger to the ear incident to nasal irrigation.

A physician not well versed in nasal diseases will do better to avoid the nasal douche and to substitute for it the liberal use of the spray from a good atomizer for the purpose of removing secretion. Though less efficient than the douche, it is safe. Its frequent employment, especially in the suppurative rhinitis accompanying the infectious diseases of childhood, lessens to a moderate extent the liability to infection of the middle ear. The material used in the atomizer is nearly irrelevant. It is the mechanical effect, which can only be obtained by a coarse, watery spray, upon which its utility depends.

Clinical Reports.

PRIMARY UNION IN A GUNSHOT WOUND.

REPORT OF CASE.

ALBERT SOILAND, M.D.

LONG LEAF, LA.

S. V. C., night-watchman at a planing-mill, was accidently shot while stooping to pick up an object from the floor, his pistol falling out of its holster and being discharged upon striking the floor. The ball, of 41-caliber size, entered the anterior fold of the left axilla, between the third and fourth ribs, and emerged at the back, between the sixth and seventh ribs, just external to the axillary border of the scapula. The patient was able to walk from the place of accident to his house, a distance of 500 yards, and when I arrived I found him bleeding profusely and complaining of an intense burning pain through the entire left side. There was very little shock noticed and he was in good spirits. The anterior wound was round, clean and surrounded by a few powder-burn marks. The posterior wound, or point of exit of the bullet, was large and ragged, and from this the hemorrhage ensued. On careful palpation I could not detect any crepitus nor signs of extravasations of blood in the pleural sac.

Treatment.—Both wounds were syringed out thoroughly with hydrogen peroxid, packed with sterile gauze, and a moderately tight bandage applied. Ten grains of citrophin were administered and a like amount ordered taken in one hour if very restless. On the following morning the dressings were removed and the same procedure gone through with as before. Pain was now nearly gone and hemorrhage reduced to a mere oozing of serum. No further internal medication was deemed necessary, as the pulse and temperature were found to be normal. A saline was administered, however, and a generous diet of easy digestibility instituted. On the fourth morning dressings were found to be absolutely dry and the anterior wound nearly closed up, the posterior being reduced to one-half its original size and filled with healthy granulations. A fresh dry dressing was now applied, plain sterile gauze being placed over the wounds and a minute quantity of iodoform was sprinkled into the meshes of the gauze, this dressing to remain on indefinitely. On the sixth day the patient walked about and suffered no inconvenience, except a little stiffness noticed in the left side. On the morning of the tenth day dressings were removed and both wounds found to be nicely healed, a firm cicatrix covering each one. That night he resumed his work as watchman, exactly ten days from the time of accident.

It might be well to state that that patient had taken a bath and donned clean undergarments just prior to the accident. He wore no coat nor vest, as the weather was extremely warm. This may account for the absence of infection and the aseptic condition of the injury throughout its course.

CASE OF TYPHOID IN AN INFANT.[*]

MINNIE C. T. LOVE, M.D.

DENVER, COLO.

The only notable thing in this case is the age of the patient. She was born March 8, 1900, so that she was 8 months old at the time of contracting the fever. When I began taking her temperature, regularly, I found it ranging between 102.5 and 103 in the mornings, and 103.5 and 104 in the afternoons. I was attending an older brother who had scarlet fever, and the mother called my attention to the baby, saying that she had had considerable fever of nights for over a week. On examination, I found rose spots on the trunk, and a dry, brown tongue. Although the clinical picture was so plain, I was skeptical, and asked Dr. J. N. Hall to see the patient with me. He was of the opinion that it was an undoubted typhoid, and the examination of the blood by Dr. Wilder, for the Widal test, confirmed the diagnosis. The course of the disease was typical, the temperature gradually declining, and reaching normal about the twenty-first day. The rose spots were very plentifully distributed over the trunk and limbs. The temperature, from about the tenth to the seventeenth day, rose to 104 F., every evening. The babe was entirely breast-fed. There was no tremor nor delirium noticeable, no tympanites and no diarrhea. This was the third case in the family since September 6. A girl of 10 years was very ill, a severe relapse prolonging the attack to over seven weeks. Ten days after the first, a child 3 years old developed a well-marked case, but it aborted about the fourteenth day. Between eight and nine weeks elapsed between the first and third cases. The mother had typhoid twelve years ago, but, as the oldest child had such a severe attack, and the 3-year old a more moderate one, we may exclude any condition of the mother's blood being transmitted to the baby which would give a Widal reaction. Unfortunately, the mother, who nursed all the children, destroyed the temperature records. This case is interesting, as it is rare to see typhoid under 2 years of age.

LARDACEOUS, WAXY OR AMYLOID DISEASE OF THE KIDNEYS.

Our knowledge of amyloid disease of the kidneys is of comparatively recent date. Rokitansky, in 1842, described the amyloid kidney as representing a special variety of nephritis. From the appearance of the organs, on account of their resemblances to bacon, he described them as *speckartig,* which has been rendered into English as "lardaceous." The term "waxy" has also been employed. Ten years later Meckel discovered the characteristic reaction with compound solution of iodin, and shortly afterward Virchow showed that this reaction was dependent not on the presence of cholesterin, but upon that of amylon, a substance resembling vegetable cellulose, and subsequently found to be a proteid.

The morbid process is a degenerative one, and, as Litten[1] points out in a recent communication, it does not generally arise spontaneously, but it is almost always secondary to some cachectic condition, especially tuberculosis, scrofulosis, suppuration of the skin, bones or mucous membranes, syphilis, intestinal ulceration, malaria, pyelitis, carcinoma, leg-ulcers of long standing, chronic bronchitis, gout, emphysema, spondylitis, pulmonary abscesses, etc. Amyloid degeneration, however, does occasionally occur independently, without apparent cause. Children are less commonly attacked by the disease than adults. The condition is most prevalent in middle life. It develops slowly, often insidiously, and it may persist for years; occasionally it is rapid in development. The spleen and the kidneys are the organs almost invariably involved earliest and in greatest degree in the morbid process, especially the former. The liver and the intestinal mucous membrane probably follow next in frequency.

One of the most usual symptoms of amyloid disease is dropsy, both of the serous membranes and of the subcutaneous connective tissues. The former most frequently takes the form of ascites, while the latter appears especially in the lower extremities, the genitalia and the abdominal walls. The exhaustion of the patient is favored by disease of the liver, the spleen and the intestines. Involvement of the intestines is usually associated with diarrhea, which is dependent in part on ulceration, and in part upon degeneration of the villi and their vessels, as well as portal stasis. Vomiting is less common, but when present it is usually obstinate; the vomited matters have at times an odor of ammonia. When the liver and the spleen are involved they may be considerably enlarged. Uremic symptoms and apoplexy are rare. Hypertrophy of the heart also is uncommon, except in the presence of contracted kidney.

Three principal varieties of amyloid disease of the kidney may be distinguished anatomically: 1. Pure amyloid disease of the vessels, with or without fatty degeneration of the cortical epithelium—pure amyloid kidney. 2. Amyloid degeneration with chronic parenchymatous nephritis—large, white amyloid kidney. 3. Amyloid contracted kidney. The first variety is not common, and it may escape recognition during life, unless coincident enlargement of the spleen indicates its presence; and even after death the disease of the kidney may not be obvious on macroscopic examination. The second variety is much more common, and the third least so. A fourth variety, rarely observed, is sometimes described, representing a combination of acute nephritis with pre-existing amyloid disease.

Amyloid disease begins in the blood-vessels, and especially in the muscular layer, though the intima and the adventitia do not, as a rule, entirely escape. Rarely the morbid process extends to adjacent tissues. Macroscopically the condition is recognizable from the peculiar luster to which it gives rise, and which has been compared to the appearance of bacon, but particularly from its reaction to certain chemical agents. Thus, addition of compound solution of iodin causes the development of a mahogany-brown color; of sulphuric acid and zinc chlorid, the development of from a violet to a blue color; of methyl-violet, an intense and brilliant red color; and of thionin, a sky-blue color.

Amyloid disease of the kidneys is supposed to begin in the glomeruli and to extend thence to the afferent vessels, the interlobular arteries, as well as the straight arteries of the medullary portion, and finally the efferent vessels and the capillaries of the cortical structure. It is not distributed homogeneously, nor does it extend by continuity or contiguity, but its distribution is rather irregular and disseminated. The lumen of the vessels may be variously narrowed, but their walls are not unduly friable, and they do not rupture.

In the majority of cases of amyloid disease of the kidneys the urine is free, pale, clear, of low specific gravity, without noteworthy sediment or the presence of morphologic elements. At times, however, the secretion exhibits great variations in quantity and quality. It has been stated that amyloid tube-casts appear in the urine; but with regard to this there is serious doubt. So, too, it has been thought that albumin is invariably present, but evidence is not wanting that this view is not strictly correct. Whether albumin will or will not appear in the urine depends, it is thought, in the first place, on the amount of albumin excreted by the kidneys, and in the second place, on the absorptive power of the uriniferous tubules. The amyloid, large white kidney is, it is true, always attended with the presence of large amounts of albumin in the urine, as is likewise the kidney when it is the seat of amyloid disease and parenchymatous inflammation.

---

[1] Berliner klin. Woch., 1900, Nos. 51 and 52.

The diagnosis of amyloid disease of the kidneys will depend essentially on a knowledge of the existence, present or past, of any of the etiologic factors named, together with a recognition of similar disease in other organs, as for instance in the liver and spleen from enlargement of these organs, or in the intestines from the presence of diarrhea. So too both prophylaxis and treatment will require a consideration of the causative conditions and the application of the necessary measures for their removal or amelioration. In other respects the therapeusis will be governed by general principles and is much the same as that indicated for the several varieties of nephritis, with which too often the amyloid disease is associated.

THE BONE MARROW AND LEUCOCYTOSIS.

In various inflammatory conditions leucocytes migrate from the vessels in enormous numbers and at the same time there usually is a more or less marked general leucocytosis. Most of the leucocytes in question are of the finely granular variety, with polymorphous nuclei—"polynuclear leucocytes." The mechanism of leucocytosis, which apparently is a very sensitive one, is not thoroughly understood. It is acceded generally that a proliferation must take place in order to account for the great increase in leucocytes in the conditions just mentioned. The exact changes that lie at the bottom of the proliferation are quite hidden as yet. We do not understand the chemical and physical processes set going by the so-called chemotactic substances of various kinds, which induce general leucocytosis and local leucocytic accumulations. This problem is one of fundamental importance, and its ultimate solution depends on other methods of observation than the prevailing morphologic mode of study. There are many things that speak in favor of the bone marrow as the ultimate source of the leucocytes that make up the great bulk of cells in local and general leucocytosis. Ehrlich, Ribbert and others hold this view, which they base on the facts that the granules of the polymorphonuclear leucocytes resemble those of certain cells in the bone marrow, and that the bone marrow undergoes a definite change when there is an increased demand for leucocytes.

Robert Muir[1] has recently given a summary of his experiments bearing on this question. According to him, the bone marrow contains three kinds of cells that are of especial interest in this connection, *a*, cells with a finely granular protoplasm form the great majority, the granules corresponding to those polymorphonuclear leucocytes in being neutrophile; *b*, cells with coarse, eosinophile granules, and *c*, hyaline or non-granular cells. Only the two first should be called myelocytes. The finely granular myelocytes have a single round, oval or slightly indented nucleus. These cells are prone to multiply, and multiplying they produce smaller cells, the nucleus of which becomes polymorphous at the same time as ameboid movement is acquired, and thus they give rise to the polymorphonuclear leucocyte of the blood. The eosinophilous myelocytes are held by Muir to produce the eosinophilous leucocyte. Muir found that the smaller finely granular cells lie at the margin of the blood channels of the marrow, thus forming a reserve store of leucocytes. When staphylococcus pyogenes aureus is injected into rabbits, leucocytosis develops after a preliminary leucopenia. Marked proliferative changes appear in the bone marrow, the finely granular myelocytes increase in number and show numerous mitotic figures, and the fat cells of the marrow are crowded out. The marrow assumes the "leucoblastic" type. Myelocytes and erythroblasts may pass into the blood stream. Muir did not find that the spleen took active part in the increased supply of leucocytes, and constant changes are not present in the lymphoid tissue in experiments of this kind.

With Ehrlich and others, Muir considers chemotaxis as the essential factor in leucocytosis. The absorption of chemotactic substances into the blood induces the passage of leucocytes from the bone marrow into the blood stream. Local and general leucocytosis is produced by a similar mechanicism. The hyperplastic processes in the myelocytes may be induced by the rapid passage of leucocytes from the marrow into the blood. The newly-formed cells constantly pass into the blood, and proliferation of myelocytes may be explained according to Weigert's theory of over-regeneration after repeated loss. Muir also suggests the possibility that the substance which acts chemotactically may also directly stimulate cellular proliferation.

MARRIAGE LEGISLATION IN MINNESOTA.

The Journal a few weeks ago briefly noticed the proposed marriage legislation in several states, and the probable difficulties in the enforcement of the laws when passed. The bill now before the Minnesota legislature is probably one of the best conceived and most practicable of these, and a brief notice of its chief provisions is perhaps not out of place. It provides that no man or woman who is epileptic, imbecile, feeble-minded or afflicted with chronic insanity shall intermarry when the woman is under the age of 45 years, and that no person not thus afflicted shall marry any one unless under severe penalties. No official shall issue a marriage license to any applicant unless, in addition to the conditions heretofore required, he shall be furnished with a certificate from a reputable physician, or physicians of the counties in which the applicants reside, certifying that on examination it has been found that there is, besides the patient's actual freedom from imbecility and insanity, no such defect in parents, grandparents, brothers or sisters. Every such certificate must be filed in the office of the licensing official. No clergyman or other person authorized to solemnize marriages shall perform the marriage ceremony for any person not thus qualified by this law, under severe penalty.

---

[1] Jour. Path. and Bact., 1901, vii, 161-183.

It will be seen from the above that the proposed law is comparatively limited in its scope, and that the provisions for its enforcement are such as may probably be fairly efficient within the state itself. The difficulty will remain that unless other, and especially adjoining, states adopt similar regulations it will be practically a dead letter, as forbidden marriages can be contracted at any time over the boundaries. This is evidently recognized, and it is said that the Minnesota authorities will ask other states to enact similar laws. It is still a question whether, in making a family taint, including both direct heredity of insanity or imbecility back several generations and collateral heredity in brothers and sisters, a bar to marriage, the authors of this proposed legislation have not gone too far. Such a law would disqualify a large proportion, if indeed not the great majority, of the members of the reigning families of Europe, and a strict construction of the act might make it inconveniently comprehensive in its workings even in Minnesota. There are possibilities of purely acquired chronic insanities involving no family taint, and some discretion, it would seem, might in justice have been allowed the certifying physician for such cases. This, it is true, would let in a chance for evasion that the present wording prevents, and this is one of the difficulties met with in all such legislation.

It will be of interest to observe the working of this and similar enactments. Something like this is on the statute books of at least one eastern state, and the experience of its enforcement might be suggestive and instructive to the Minnesota legislature. In any case there is no question as to the desirability of checking the degenerative tendencies of modern life and the propagation of degenerates, and the experiment of legislation to that effect will be of value—possibly in its effects, certainly in its instruction.

BACTERIOLOGY AND PATHOLOGY OF DIPHTHERIA.

An important monographic study of the bacteriology and the pathology of 220 fatal cases of diphtheria, by Councilman, Mallory, and Pearce, has just appeared as a number of the *Journal of the Boston Society of Medical Sciences* (1901, v, No. 5). As pointed out in the introduction, diphtheria may now be considered as the best known of any of the infectious diseases. The study devoted to this disease has "in a marked degree increased our knowledge of pathological anatomy, of bacteriology, and of therapeutic measures in infectious diseases. In no other disease has the discovery of the cause led to measures of prevention and of cure which have been rewarded by such brilliant success."

Diphtheria was first described definitely by Bretonneau in 1826. Now its literature has grown to enormous proportions. The development of the different phases of our knowledge of the disease—the pathological anatomy, the bacteriology, and the antitoxic treatment—has in each instance led to the production of numerous articles. There are, however, a comparatively small number of articles each one of which represents an important increase of our knowledge. The authors of this monograph divide the literature of diphtheria from this point of view as follows: First recognition of the disease, Bretonneau; its recognition clinically as a specific contagious disease, Trosseau; anatomic investigation of the membrane, and its mode of formation, Virchow, Wagner, Weigert, Cohnheim and others; the remote lesions, Bizzozero, Oertel, Babes; discovery of the bacillus, its relation to the disease, and the study of experimental lesions, Klebs, Loeffler, Roux and Yersin and others; discovery of antitoxin, Behring, Roux; clinical evidence of value of antitoxin, Welch, McCollom and others. This outline well shows the development of our present knowledge of the disease. The present monograph comes as a fitting addition to this list. Naturally there is but little new added to what is known, although it is quite evident that all investigators do not agree on all points. This is especially true of many questions of a histopathologic nature.

An honest and skilful study of the anatomic and bacteriologic details of 220 cases of diphtheria is sure to become a permanent landmark in the literature of the disease. But the work has another significance that can not be too strongly emphasized. It shows what may be accomplished when the services of a large public hospital are properly organized, co-ordinated, and manned. All of the 220 cases referred to came from the so-called South Department of the Boston City Hospital—a department of 300 beds devoted to the infectious diseases of children, and the anatomical and bacteriological work was carried out in the pathological laboratory of the hospital. Here we have a striking example of the highest grade of scientific clinical and pathological work carried on year after year within the walls of the city hospital of a large American municipality. It is a noteworthy example for other hospitals of similar type; for so few of them are organized and managed in such a manner that this high grade of work is fostered. And surely the hospital that is devoted to scientific ideals takes the best care of its patients. Let physicians in the recurring scrambles for positions in the large hospitals of our cities think more of this side of the question than of a brief period of apparent authority.

THE JAPANESE AND OPIUM.

The use of opium in China is apparently regarded by the Japanese authorities as one of the causes of the decadence of that empire. To such an extent does this feeling exist that it is said that out of a number of Japanese coolies employed in the China-Japanese War, a certain portion contracted the opium habit and for this were brought before the Japanese commander. Rather than allow them to return to Japan and introduce the habit there, it is reported that he had them lined up and shot. Considering the community of political interests in the Orient, and general friendly feeling between Japan and Great Britain, the pro-opium tendencies of the British government are perhaps worth considering as bringing in a discordant element that may give trouble in the future.

"ELÆOMYENCHYSIS."

THE JOURNAL is always glad to furnish information desired by its eastern contemporaries. In a recent issue of a New York medical journal, the leading editorial, on "Therapeutical Injections of Solidifying Fats," stated that the editor did "not know where Gersuny's work in this direction was done or where the original account" was to be found. Gersuny's original article appeared in the *Zeitschrift für Heilkunde* (Bd. xxi, Heft 9), and was abstracted in the *Wiener Klinische Wochenschrift* (No. 51, Dec. 20, 1900, p. 1207). The *Semaine Médicale,* of Paris, published Gersuny's article in its issue of December, 19, 1900, without giving credit to any other journal. This article was abstracted in THE JOURNAL of January 19, 1901, p. 219, and a further reference to the injection of paraffin for surgical prothesis may be found in the issues of February 23 (p. 532) and March 16 (p. 775).

THYROID TREATMENT AND OPTIC NEURITIS.

The usual symptoms of thyroidism, emaciation, weakness, shortness of breath, nervousness, etc., are well known, but there are others occasionally observed that are less generally appreciated. If we are to regard exophthalmic goiter as the result of hyperthyroidization, we can see possibilities in the way of unpleasant symptoms that have not all been actually observed from the therapeutic use of the extract. However that may be, it is probable that observations on the increasing therapeutic use of the drug will from time to time bring out many important additions to our knowledge of its effects. One such has been editorially noticed in the *Medical Press and Circular* for March 6. The reference to the record is not given, but it states that Dr. Coppez, of Brussels, reports the cases of five patients, four of them women, in whom prolonged thyroid treatment for obesity produced well-marked optic neuritis, occurring several months after the beginning of the treatment, but then progressing very rapidly, vision being reduced to one-tenth in the course of a few weeks. No other symptom of thyroid intoxication appeared in these cases, but in some of them suspension of the administration sufficed to relieve the condition, and its connection with the treatment therefore seemed obvious. In other cases a prolonged course of tonics and the use of electricity were required. As the writer remarked, henceforth the inquiry as to the use of thyroid treatment will be in order in cases of optic neuritis of obscure etiology.

REPORT OF THE YELLOW FEVER COMMISSSION OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

Last summer the Liverpool School of Tropical Medicine sent Dr. Herbert E. Durham and Dr. Walter Myers to Para, Brazil, for the purpose of studying yellow fever. About two months ago both these investigators were attacked by yellow fever. Unfortunately Dr. Myers died, as noticed in THE JOURNAL. Dr. Durham, who recovered, has issued preliminary reports[1] of the results so far obtained in their work. These were printed in THE JOURNAL of March 9, p. 679, and show that they have found a fine, small bacillus in the organs of all fatal cases of yellow fever examined. This bacillus is found in the contents of the lower intestine, also in great preponderance over other micro-organisms. While it is likely that this bacillus has been seen by Sternberg and other observers, the reason that it has been accorded little or no notice heretofore is probably due to the difficulty with which it is stained. Prolonged staining in diluted carbol-fuchsin (Ziehl) is necessary to bring out the organism. So far pure growths have been secured only by placing whole mesenteric glands in broth under atmosphere of hydrogen. Search is now in progress for suitable culture-media. Protozoa have not been found. The reports state that the evidence in favor of the fine small bacillus is regarded as stronger than for any other pretended yellow fever germ, but there is much work yet to be done in order to definitely establish this claim. The death of Dr. Myers must be regarded as a loss to medical science. His work gave promise of fruitful activity as an investigator. In commenting on the report of Drs. Durham and Myers, Professor Welch, of Baltimore, writes: "Both Lazear of the American and Myers of the English yellow fever commission have laid down their lives in the search for means of prevention, based upon better knowledge of causation, of one of the most baffling and terrible scourges of mankind. How much more glorious is the cause to which these bright young lives were sacrificed than any for which nations are in arms to-day!"

"IMMUN-PROTEIDINS."

An abstract appears elsewhere in this issue (p. 929) of THE JOURNAL giving the details of certain interesting experimental studies by Emmerich and Löw, on the production of immunizing and curative substances. Emmerich and Löw belong to that large school of investigators which believes that acquired immunity and the healing of some infectious diseases are produced by soluble chemical substances of the nature of bacteriolytic enzymes. The source of these substances has been much discussed, some finding it in the serum of the blood and other fluids, others in leukocytic and other cells. Emmerich and Löw, however, claim that these bacteriolytic substances are produced by the bacteria themselves in the same way as it is thought that in cultures injurious substances appear and cause the organisms to die out. These substances are regarded as enzymes formed from zymogens in the bacteria. These enzymes are proteolytic and destroy the bacteria by which they are formed; and in some instances they also destroy and dissolve many other bacteria as well. Thus the ferment derived from Bacillus pyocyaneus—pyocyanase—destroys large numbers of anthrax, typhoid, diphtheria and plague bacilli, as well as diphtheria toxin. Furthermore, pyocyanase cures animals infected with anthrax bacilli. When bacteriolytic ferments develop in the living body, they may unite with proteids and form stable and durable compounds, possessing the bacteriolytic and perform the marriage ceremony for any person not thus qualified by this law, under severe penalty.

---

[1] JOURNAL A. M. A., March 9, pp. 673 and 679.

It will be seen from the above that the proposed law is comparatively limited in its scope, and that the provisions for its enforcement are such as may probably be fairly efficient within the state itself. The difficulty will remain that unless other, and especially adjoining, states adopt similar regulations it will be practically a dead letter, as forbidden marriages can be contracted at any time over the boundaries. This is evidently recognized, and it is said that the Minnesota authorities will ask other states to enact similar laws. It is still a question whether, in making a family taint, including both direct heredity of insanity or imbecility back several generations and collateral heredity in brothers and sisters, a bar to marriage, the authors of this proposed legislation have not gone too far. "IMMUN-PROTEIDINS."

An abstract appears elsewhere in this issue (p. 929) of The Journal giving the details of certain interesting experimental studies by Emmerich and Löw, on the production of immunizing and curative substances. Emmerich and Löw belong to that large school of investigators which believes that acquired immunity and the healing of some infectious diseases are produced by soluble chemical substances of the nature of bacteriolytic enzymes. The source of these substances has been much discussed, some finding it in the serum of the blood and other fluids, others in leukocytic and other cells. Emmerich and Löw, however, claim that these bacteriolytic substances are produced by the bacteria themselves in the same way as it is thought that in cultures injurious substances appear and cause the organisms to die out. These substances are regarded as enzymes formed from zymogens in the bacteria. These enzymes are proteolytic and destroy the bacteria by which they are formed; and in some instances they also destroy and dissolve many other bacteria as well. Thus the ferment derived from Bacillus pyocyaneus—pyocyanase—destroys large numbers of anthrax, typhoid, diphtheria and plague bacilli, as well as diphtheria toxin. Furthermore, pyocyanase cures animals infected with anthrax bacilli. When bacteriolytic ferments develop in the living body, they may unite with proteids and form stable and durable compounds, possessing the bacteriolytic and antitoxic properties of the ferment, and this in even greater degree. This, in brief, is Emmerich and Löw's theory of the chemistry of immunity and of the healing of the infectious disease, more especially the septicemic, such as anthrax and swine erysipelas. The compound of ferment and proteid is designated as "immun-proteidin." It is of complex molecular structure, not readily subjected to osmosis, consequently more or less persistent. When present in an organism it confers a certain degree of immunity, corresponding to the amount present. In the article abstracted the authors dwell especially upon the artificial production of immunproteidins outside of the animal body. But the method evolved is as yet far from perfect and the beginner who undertakes to test the method is specifically cautioned against condemning the method because of failure at the first attempts.

---

[1] Journal A. M. A., March 9, pp. 673 and 679.

NEWSPAPER IGNORANCE AND SCIENTIFIC MEDICINE.

The death of Ex-president Harrison is taken as a text for abusing the medical profession by one of the quack-favoring dailies. It calls the event a "conspicuous instance of the helplessness of the medical profession when confronted by certain cases of diseases." Pneumonia, it says, while it is "always dangerous, is seldom deadly," and it suggests what a storm would have been raised if the ex-preident had trusted himself to the osteopaths or "Christian Scientists." The editorial is a type of many now appearing, inspired by ignorance and malice, and the question often arises whether such utterances are unworthy of notice or should be taken up and resented. Under ordinary circumstances it would hardly be worth the trouble to notice them, for they usually defeat their own purpose by their rank exaggeration and evident inspiration by prejudice and ignorance. It does not require much intelligence to recognize the fact that medicine has earned the confidence of the public by its success, and to perceive the probability that this same caviling editor would throw himself into the hands of a physician did he think himself the victim of a dangerous or troublesome disease. An average intellect can perceive that the death of so prominent an individual under the ministration of voodooists or ignorant masseurs or bone-setters might reasonably arouse comment and sins of omission be charged. The editor and the public do not apparently know, however, that for six months of the year pneumonia is one of the most fatal of all diseases in our northern climate, and with its la grippe complications incomparably the most fatal. Moreover, it is the disorder which, more than others in recent years, has been one of the least amenable to control, and its mortality is increasing while that of other diseases, like tuberculosis, is decreasing. The editorial referred to is simply an exhibition of ignorance in this respect. There is a sort of cheap self-consciousness of virtue and liberality indulged in by editors and others that shows itself in taking up and supporting self-assertive frauds and denouncing the bigotry of those who, with better knowledge, are compelled to conscientiously oppose them. It does not matter to such that a little investigation of facts and a limited utilization of their intellects would demonstrate to them the error of their ways. They are too well satisfied with things as they are. In the meantime medicine and the medical profession will continue to follow the scientific paths and do all they can to lead mankind into the ways of bodily salvation.

MALARIA FROM AN ECONOMIC STANDPOINT.

One is surprised on reading Celli's books[1] on malaria, recently translated into English, to see how this authority has quite subordinated the scientific and medical view to the social and economic, or rather, how he has utilized scientific and medical truths to solve those of an economic and social nature. Some facts presented are almost startling. For instance, he tells us that in Italy the mean annual mortality from malaria is about 15,000, and the number of those who suffer from the disease he estimates at 2,000,000 a year, with a rather long average duration of illness. The loss in productiveness of labor and productions and the expense entailed in dealing with this disease consequently amount to several million francs. Because of malaria more than 5,000,000 acres of land are imperfectly cultivated, and in these localities the average life of the workman is shorter, the infant mortality higher, and the number of emigrants greater than would otherwise be the case in healthy places. The economic loss from malaria is, therefore, enormous. Some of the railways have to reckon on a certain sum to be expended annually on account of malaria. One company with about 850 miles of railway, and employing 6416 workmen, spends $200,000 a year for this reason. The army has averaged about 15,000 cases a year for twenty years. One can thus see how the question is of prime importance to the state, and how legislation may be necessary to secure those conditions that will tend to check the development and the spread of the scourge. Attention must be given to destruction of the breeding-places of the mosquito. Forests, standing or sluggish water, rice and cane fields, peat bogs, fish-ponds and certain industries, such as the maceration of hemp, must be under governmental supervision. In fact, laws regulating the cultivation of rice, where the wet fields afford excellent breeding-places for the mosquito, have been for years on the statute books, placed there even before the relation of the mosquito to the disease was known.

The insect in its larval state must be subject to government attack. And laws may be necessary to regulate the proper building of houses, the screening of the doors and windows, the furnishing of proper food and clothing to the laborer by his employer, the compulsory isolation of those ill with malaria, etc. Realizing that the vulnerability of an individual to disease may depend much upon proper food, clothing and hygienic surroundings, when we read of the condition of the Italian laborers as it is depicted by Celli, how they are often huddled together in wretched huts or even caves, underfed, insufficiently clothed, overworked yet poorly paid by the capitalist land owner with his hireling overseers, we can well understand the earnest words that the author pens in an almost socialistic strain, and can see how the mosquito is perhaps destined to play a not insignificant part in improving the condition of the poor in Italy and in bringing about a social revolution.

---

[1] Celli, Angelo: Malaria According to the New Researches. Translated from the second Italian edition by John Joseph Eyre. Longmans, Green & Co. 1900.

What is said concerning the sociologic and economic view of the mosquito in Italy will apply with greater or less force to other malaria-scourged lands, even to including our own country, especially since it is now responsible for the welfare of the newly-acquired tropical possessions.

THE INFLUENCE OF SERUMTHERAPY ON DIPHTHERIC STENOSIS OF THE LARYNX.

It has been objected by those who are not convinced of the efficacy of the antitoxin treatment of diphtheria, that since this method has been introduced into hospital practice a relatively larger number of mild cases are admitted into the hospitals. Even were this objection supported by the facts, it would admittedly not be applicable to private practice. It has further been suggested that both in hospitals and in private practice a change in the character of the disease has taken place, in the direction of an attenuation in its virulence and a lessening of its fatality; but even did such a variation coincide with the introduction of serumtherapy, it would be applicable to mild and severe cases collectively. and not to severe cases alone. To eliminate these objections as far as possible, Galatti[1] has made a study of the cases under his observation in which symptoms of laryngeal stenosis were present, and his services were invoked in consultation with other physicians for the purpose of performing intubation. Sixty-one carefully observed cases seen in the course of several years—29 before and 32 since the introduction of serumtherapy—were analyzed. Intubation was advised against in 20 of these, such treatment being meanwhile employed as was in vogue at the time. Of the 29 cases of laryngeal stenosis prior to the employment of serumtherapy, recovery occurred in 6—21 per cent.—without operative intervention, while of the 32 cases during the antitoxin period, recovery ensued in 14 or 44 per cent. without operation. A comparison of the cases subjected to intubation in the pre-antitoxin period with the cases of laryngeal obstruction treated with antitoxin, and thus escaping intubation, as well as with cases requiring intubation, showed that there was little difference between the several groups of cases with regard to severity. The lessened necessity for intubation was not found to be dependent on differences in age, as the improvement was noted equally in earlier and in later childhood. In the pre-antitoxin period, intubation had to be supplemented by tracheotomy in 1 case, and in the antitoxin period in 5 cases. This circumstance must be considered as indicative of the gravity of the cases of the latter group. Of the 23 intubated cases of the first period, death occurred in 11—47.8 per cent; while of the 18 intubated cases treated with antitoxin, death occurred in 1, or 5.5 per cent., and this probably because of the small dose employed. The period for which intubation had to be maintained was *shorter* in the serum-treated than in other cases, being on an average fifty-seven hours for the former and seventy-eight and one-half for the latter, the contrast being particularly marked in the cases in which recovery ensued, namely, as 58 to 108. The length of the period in individual cases varied between thirty and seventy-nine hours in the cases treated with antitoxin; and between thirty-one and forty-three and three-fifths hours in the cases treated in the pre-antitoxin period.

Medical News.

ARKANSAS.

A unique bill has been introduced in the legislature, to prevent physicians and surgeons from practicing if they use intoxicating liquors as beverages.

The State Board of Health has been organized, with Dr. George M. D. Cantrell, Little Rock, president, and Dr. Robert B. Christian, Little Rock, secretary.

CONNECTICUT.

A sanatorium for consumptives is to be built on Cedar Hill, three miles from Hartford, on land owned by the Hartford Hospital.

The citizens of Westville, New Haven, held a mass meeting and have protested against the establishment of a hospital for contagious diseases in that village.

Dr. Joseph H. Townsend, New Haven, has been appointed a member of the State Board of Health, vice Dr. G. Herrick Wilson, Meriden, whose term has expired.

Physicians have appeared before the judiciary committee of the legislature in behalf of the medical practice act with especial reference to reciprocity in certificates between the various states.

DELAWARE.

Dr. Joseph W. Bastian, Wilmington, has been appointed port physician.

Delaware Hospital, Wilmington, has received $5000, a legacy under the will of Mrs. Sarah Esther Cummins, of Smyrna, to endow a bed in memory of her parents.

The Abbott bill, which permits physicians who have practiced ten years in another state and have resided one year in Delaware, to practice in Delaware without undergoing an examination, is meeting with vigorous opposition from the reputable physicians of the state.

Smallpox prevails in Seaford, where it was discovered seven weeks ago. The disease is said to be confined mostly to negroes, and up to March 13, about 50 cases had been reported. On that date members of the State Board of Health visited the town and promulgated regulations providing for thorough vaccination and quarantine, to include obstructing of the town; appointment of inspectors and thorough antiseptic bathing of patients, and complete disinfection, private interment and abolition of all public assemblages. Georgetown has decided to place armed pickets along the roads leading from Seaford, in order to prevent the disease from spreading to that town. Every resident has been ordered to become vaccinated under a penalty of $10 fine.

ILLINOIS.

A Jerseyville practitioner was fined $100 and costs, March 12, for practicing medicine without a license.

Rockford City Hospital's consulting staff, on March 15, elected Dr. Daniel Lichty, president, and Dr. Sanford R. Catlin, secretary.

A fine was imposed on a Clinton physician, on March 14, for failing to report a case of contagious disease to the local board of health.

Quarantine of Salisbury, on account of smallpox, is said to be contemplated by the State Board of Health. As usual, the local physicians deny the existence of the disease.

Dr. George A. Zeller, Peoria, who went to the Philippines two years ago as acting assistant surgeon, has been promoted and now holds the rank of captain and assistant surgeon of volunteers.

Dr. James A. Egan, secretary of the State Board of Health, has been nominated and appointed a member of the State Board of Health, to succeed Dr. Peter H. Wessel, Moline. In his communication to the senate, the governor says: "This appointment is made because I deem it best that the secretary of the State Board of Health should be a member of the board."

Chicago.

Dr. Niles T. Quales, who was injured by an accident, March 15, and taken to the Deaconness Hospital, is now convalescent.

County Hospital Staff.—The following-named physicians have been appointed on the assistant staff of Cook County Hospital: F. Gregory Connell, Maurice L. Goodkind, Arthur M. Corwin, Carl J. Anderson, Bertram W. Sippy, Henry F. Lewis, William A. Quinn, Amuel B. Spach, William A. MacFarlane.

---

[1] Wiener med. Woch., 1901, Nos. 2 and 3.

John E. Rhodes, August F. Lemke, Arthur D. Houghton, George E. Thompson, David J. Doherty, Henry J. Brugge, and Patrick J. H. Farrell, of Chicago, and Dr. William R. Livingston, Maywood.

Decreased Mortality of Chicago.—There have been 581 fewer deaths this year, up to the close of last week, than during the corresponding period of 1900. This is a decrease of nearly 10 per cent. In the first twenty-three days of March there were 1451 deaths from all causes, as against 1833 in the similar period last year—a reduction of a little more than one-fifth. Last week the total reported deaths numbered 465; for the corresponding week one year ago, 640, or 30 per cent. more. This low mortality record, which has now been maintained since the end of the fourth week of January—up to which date the deaths this year slightly exceeded those of last, the respective totals then being 2095 and 2056, is without parallel in the history of the city. In the presence of influenza and smallpox it is nothing short of marvelous. The deaths from diseases of the respiratory system numbered 173, diseases of the heart caused 33, and nervous diseases, 34 deaths; violence is noted as the cause of death in 33 instances.

Unvaccinated School Children.—Judge Dunne's ruling that unvaccinated children can not be excluded from schools until an emergency exists, is susceptible of various and dangerous interpretations. Dr. Spalding, chief medical inspector of the health department, says that there is always an emergency. The office of the health department is to prevent, not to cure disease. As a result of the extraordinary precautions against smallpox, of the 138 cases of the malady this winter only 4 were of school children, and not one of these children had been vaccinated, but each was attending school on false certificate of vaccination. Smallpox takes hold rapidly. If Chicago had not been thoroughly vaccinated when smallpox broke out last year there would have been a great epidemic. Children being more susceptible to the disease, as they are to all contagious diseases, would have been the first to suffer. The history of smallpox in the city shows that in the epidemic of fourteen years ago 40 per cent. of the children stricken died, while the general mortality was only 25 per cent. In 1893 there were 4000 to 5000 cases, and the children furnished a heavy proportion of them.

IOWA.

Dr. Charles R. Russell, Ottumwa, was elected state physician of the Knights of the Maccabees, March 15, by a large majority.

Dr. William S. Grimes, Wapello, has been appointed a member of the pension examining board, vice Dr. G. W. Younken, resigned.

Dr. Maurice A. Hanson, Osage, is about to take a three-years' post-graduate course in Vienna, devoting his attention chiefly to surgery.

Dr. Edward E. Dorr, Des Moines, has started a movement for the transfer of the medical school of the state university from Iowa City to Des Moines.

MARYLAND.

Baltimore.

Dr. G. Lane Taneyhill has been elected first vice-president of the Baltimore City Missionary and Church Extension Society of the M. E. Church.

Dr. Schwatka, the new surgeon-general of Maryland, is outlining a plan whereby the duty of the medical officers and hospital corps of the national guard shall not be purely ornamental. His plan provides for a thorough course in field-hospital work.

Notes from Osler's Clinic.—Of 51 cases of lobar pneumonia in the hospital this session, there have been 14 deaths. There were 24 cases of typhoid fever; in 9 of these there were relapses; in 12, the typhoid bacilli were isolated from the blood, in 4 of these before the Widal reaction appeared. Two cases of typhoid fever were admitted to the surgical side and operated on for appendicitis.

Pneumonia Antitoxin.—The recovery of Quarantine Physician Sydney O. Heiskell, from pneumonia, following rapidly on two injections of pneumonia antitoxin, is attracting much attention. He testified to the great relief it gave, which morphin failed to give. From a statement made at the health department, it is learned that members of the department first used the serum in 1899, Dr. C. B. Canby publishing successful results in three or four cases. Other cases were known to have been successful and there was one failure. In all there was almost immediate relief from pain and oppressed breathing. Such relief is confidently looked for within four hours. The injection should be given as soon as the diagnosis has been made, and repeated every four to six hours until results are obtained. It is only in the pneumococcus that the antitoxin is of service. In Heiskell's case, treatment was instituted in twenty-four hours. At 4 p. m. the temperature was 102 degrees, respiration 35 and pulse 100; sputum rusty. At 5.45 p. m. 20 c.c. of serum was injected. At 10 p. m. the temperature was 100.6 degrees; respiration, 30, and pulse 98. A second injection was given and at 4 a. m. the temperature was 99.6 degrees; respirations, 25, and pulse 90.

MASSACHUSETTS.

Dr. James C. D. Clark has been appointed city physician of Medford.

Dr. Mary P. Dole, Greenfield, has been elected a member of the board of managers of the Franklin County Hospital.

Dickinson Hospital, Northampton, is to be given a new operating-room fully equipped, as a memorial of a citizen of Northampton.

Anne Jaques Hospital, Newburyport, in one week has received a $10,000 bequest from Mrs. Sophia C. Hale, and an offer of a $5000 site and a $50,000 new building from William C. Todd.

Amendment to Registration Law.—Dr. Immanuel Pfeiffer, North Adams, has urged before a legislature committee the adoption of amendments to the law regulating the registration of physicians and surgeons. As finally presented to the committee the petition asked that any person having a diploma from a recognized medical college shall be registered without examination; that the fee for registration be reduced from $20 to $10; that such fees shall be paid into the state treasury; that all expenses and salaries of members of the State Board of Registration in Medicine shall be paid from the treasury; that such salary and expenses shall not exceed $1200 annually for any single member of the Board, and that all examination papers shall be open to the inspection of physicians for three years after such examination.

MINNESOTA.

By the will of Mrs. George A. Pillsbury, Minneapolis, the Northwestern Hospital in that city received $10,000.

Temperance is the text of a bill introduced by Representative Sageng, Otter Tail, which makes it a misdemeanor for physicians or surgeons to administer medicines or perform operations when under the influence of liquor.

The St. Paul physician charged with violating the health ordinance in failing to report a case of smallpox was discharged March 17, the judge holding that there was no evidence to show that the defendant recognized the case in question as being smallpox.

Members of Health Boards.—Amendments to the laws have been presented by Senator Chilton, which provide that county boards of health shall consist of the county attorney and a physician, the latter to be the health officer and to be selected by the county commissioners; that township boards of health shall be composed of the supervisors, who may select a physician or local health officer; that village boards of health shall consist of three members, one of whom shall be a physician, and that the secretary of the State Board of Health must be a physician.

MISSOURI.

The Hall medical bill has been signed by the governor, and becomes operative ninety days after the adjournment of the legislature.

Mumps is epidemic in St. Louis. Physicians estimate that there are 20,000 cases in the city at present, and that in 85 per cent. of the cases the disease was preceded by influenza.

Columbian Medical College, Kansas City, has held its annual commencement exercises, March 19, and graduated a class of 14. The annual address was delivered by Rev. George H. Combs, D.D.

Ensworth Hospital Medical College, St. Joseph, held its graduating exercises March 18, and granted diplomas to a class of nine. Prof. B. Macafee, president of Park College, Parkville, delivered the address to the class.

NEW HAMPSHIRE.

Margaret Pillsbury Hospital, Concord, is a beneficiary to the extent of $25,000, by the will of Margaret A. Pillsbury.

Manchester's Board of Health, at its annual meeting, reelected Dr. William M. Parsons as its medical adviser and health officer.

The State Board of Health has taken forcible possession of one of the boarding houses of the Cheshire mills, at Harrisville, for use as an isolation smallpox hospital. For three weeks the contagion has been raging and on the increase.

NEW YORK.

Dr. Roland H. Stubbs has been elected health officer of Waterford.

Dr. William E. Johnson, Waverly, has been appointed secretary to the state health commissioner.

Minerva offers inducements to a young medical man looking for a location. At a recent town meeting it was voted to pay a physician $500 a year if he will only settle there. The town has a population of 1052.

Legislation on Practice.—A bill has been introduced providing that no person shall practice hypnotism, mesmerism, suggestive therapeutics and allied phenomena after May 1, unless previously registered and legally authorized, or unless authorized by the Regents. Candidates are required to show evidence of good general education and of having studied medicine in a medical school for at least two full school years. The penalty for violation of the provisions of this bill is a fine of not more than $250 or imprisonment for six months for the first offense.

Buffalo.

Dr. Fred A. Pitkin has been appointed house physician to the German Hospital.

Dr. Nelson A. Wilson has been appointed sanitary officer of the Pan-American Exposition.

German Hospital Staff.—The election of officers on the medical staff of the hospital resulted as follows: Dr. Charles H. W. Auel, president; Dr. Marcello Hartwig, vice-president, and Dr. Charles Weil, secretary. The position of clinical pathologist was filled by the election of Drs. William G. Bissell and Albert E. Woehnert.

Erie County Hospital Staff.—At a recent meeting of the Erie County hospital staff, Dr. Harvey R. Gaylord, Vertner Kenerson and Marshall Clinton were elected to fill positions on the attending surgical staff made vacant by the resignations of Drs. Eugene A. Smith, John Parmenter and Herbert Mickle.

New York City.

Dr. Francis Delafield, who has so long occupied the chair of practice of medicine in the College of Physicians and Surgeons, has resigned and will be succeeded by his clinical assistant, Dr. Walter B. James.

St. Luke's Hospital is to sell the remaining five lots of its old site on Fifth Avenue, for $575,000. The market value of its remaining real estate is $2,326,000, and the cash value of its *personal* assets $1,180,260.

New Maternity.—Application has been made for articles of incorporation of a new maternity hospital, to be known as the Manhattan Maternity Hospital and Dispensary. A wealthy gentleman, whose name is at present withheld, has donated a sufficient sum to build and equip the hospital, and partly maintain it for a term of years. It will have a small indoor service for especially severe and complicated obstetric cases, but its special sphere of usefulness is stated to be the carrying on of a large tenement-house midwifery service. In this respect its work seems to overlap that of the other maternity hospital which has become so well known because of the million-dollar donation of J. Pierpont Morgan.

OHIO.

Dr. Najib Taky-ud-Deen, Assistant-Surgeon. U. S. A., is ordered for duty to Columbus Barracks.

Dr. Raymond E. Whelan, Youngstown, has been promoted from acting asstistant-surgeon to captain and assistant-surgeon of volunteers.

Dr. August Ravogli, Cincinnati, has been appointed a member of the State Board of Registration, for a term of seven years, to succeed himself.

Dr. Jerome B. Thomas, Dayton, who has been for some time an acting assistant-surgeon in the army, has been made captain and assistant-surgeon of volunteers.

PENNSYLVANIA.

Dr. J. Linton Harkness, Philadelphia, has been appointed resident physician at the Pottstown Hospital.

Lancaster County Hospital for the Insane, which has been erected at a cost of $72,000, was opened March 13.

Dr. Fred R. Underwood, London, has received an appointment as acting-assistant surgeon in the army and has been ordered to report for duty at Fort Leavenworth, Kan.

The Pottstown Board of Health has adopted a resolution declaring tuberculosis contagious and placing it among the list of infectious diseases, and the public has been warned to take the same precautions as in case of typhoid fever and diphtheria.

Refuse Vaccination.—The teachers' committee of the school board of Harrisburg has been notified that 750 pupils in the public schools of that city refuse to comply with the state law requiring them to become vaccinated. They have been notified that if they fail to be vaccinated before March 20 they will be excluded from the schools.

Hospitals in Cities.—Judge J. D. Shafer, of Pittsburg, on March 16 handed down a decision regarding the erection of hospitals in built-up portions of cities to the effect that this law did not prevent hospitals from having additions made, but that it prohibited the erection of new hospitals. This decision may have an important bearing on the generous gift to Pittsburg, by the late Christopher Magee, providing for the construction of a large hospital in the residence portion of that city.

Philadelphia.

The annual prize of a complete "Surgical Anatomy" offered by Dr. John B. Deaver to the graduating class of the University of Pennsylvania, has been awarded to Albert Griffith Miller for his essay on "Appendicitis."

Dr. Robert P. Robins, who served as acting assistant surgeon and was in charge of the Second Reserve Hospital at Malate, near Manila and was made captain and assistant surgeon of volunteers a year later, has been promoted to major and surgeon of volunteers.

RHODE ISLAND.

A general hospital for Pawtucket and Central Falls is being strongly urged by the Pawtucket Medical Society.

The Boston Medical Library has received from Dr. Horatio R. Storer, Newport, a valuable collection of 2300 medical medals. It is to be known as the Storer Collection of Medical Medals, in memory of Dr. D. Humphrey Storer, father of the donor.

Medical Practice Act.—An act has been introduced in the house of representatives which provides that all applicants for authority to practice medicine will be compelled to take an examination instead of being admitted by diploma as at present. It gives the state board of health authority to grant certificates and provides for an appeal from the state board to the supreme court.

WASHINGTON.

Dr. Donald G. Russell, Spokane, has been reinstated as surgeon for the Great Northern Railway Company, and in addition has been appointed chief surgeon to the Spokane Falls and Northern and the Kootenai Valley and Bedlington and Nelson Railways.

Dr. James R. Yocum, Tacoma, president of the State Board of Health, has given the governor and legislature timely warning regarding precautions to be taken against the invasion of bubonic plague. He urges that the state board of health be empowered to establish such a system of quarantine inspection as will prevent the introduction of the plague at any port in the state, and insure its suppression should it creep in.

WISCONSIN.

Dr. William C. F. Witte, Milwaukee, has been critically ill from infection of a finger during an operation, but is now improving.

Dr. Charles E. Ide, formerly interne at Passavant Memorial Hospital, Chicago, has been appointed to a similar position in the Johnston Emergency Hospital, Milwaukee.

An unlicensed practitioner of Stanley, who was arrested a month ago for practicing medicine without a license, was fined $50, March 22, but the fine was remitted on his promise not to repeat the offense.

Mrs. Mary Deleglise, *Antigo*, has deeded a block of valuable land to be used as a hospital site, on the condition that a $10,000 hospital be erected thereon and that the institution shall care for her two invalid sons during their lives.

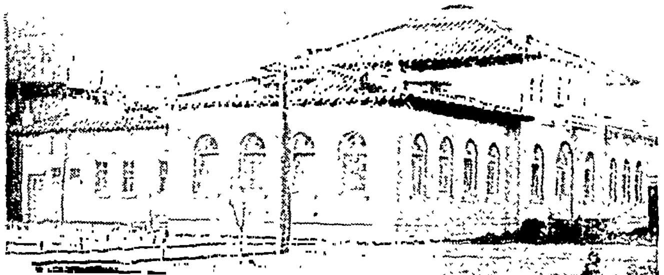
Dr. Gilbert E. Seaman, Milwaukee, has been commissioned assistant surgeon in the Wisconsin National Guard and assigned to the First Regiment. He had previously seen service in the Spanish-American war and in the Philippine Islands.

GENERAL.

Yellow Fever Precautions.—It having been brought to the attention of the Marine-Hospital Service that smallpox exists in an epidemic form at Progreso, Yucatan, the acting assistant surgeon of that service, formerly located at Vera Cruz, Mexico, has been transferred to Progreso, while another acting assistant surgeon has been transferred from Habana to Vera Cruz. The duties of both these officers will be to inspect all vessels leaving those ports for ports in the United States or its dependencies, and also to inspect the passengers and their baggage. All baggage which requires such treatment will be disinfected before shipment. This action was intended specially for the protection of Cuba.

Appointments.—Following the usual custom, the U. S. Marine-Hospital Service has detailed the following named acting assistant surgeons for duty at the fruit ports of Central and South America, during the coming close quarantine season: Paul Osterhout, Bocas del Toro, Colombia; D. W. Goodman, Port Limon, Costa Rica; W. K. Fort, Livingston, Guatemala; S. H. Backus, Puerto Cortez, Honduras; W. H. Carson, Bluefields, Nicaragua; R. H. Peters, Ceiba, Honduras; J. Grey Thomas, Belize, British Honduras. It will be the duty of these officers to supervise the loading of fruit at each of the ports mentioned, to inspect the vessels, their passengers and crews, and to disinfect such baggage as requires this treatment, with a view to preventing the introduction of yellow fever into the United States.

Emergency Hospital at the Pan-American Exposition.—In the hospital building, which has been located near the west end of the Mall, for the Pan-American Exposition, floor area is a prominent feature, and the free Spanish renaissance has been followed in the architectural work, with a tendency toward the old mission interpretation. The hospital has a frontage of 90 feet on the Mall, and the main wing a depth of 38 feet, being but one story high, except in the center, where it assumes the form of a square tower with a rounded top. This tower is two stories high, and bears two flagstaffs, one supporting the exposition flag, and the other the Red Cross banner. A rear wing, one story high, runs back from the center portion a distance of 56, with a width of 32 feet. A low wandering adobe mission house covered with heavy red tiling, may be readily imagined from the external architecture, but within everything is modern, and approved medical and surgical appliances have been selected with regard to their adaptability to emergency work and the exigencies that are likely to arise. The main office contains telephone and electrical annunciator, and messenger call service, etc. The first floor front contains, in the extreme western wing, two male wards with seven cots each, a bathroom, physicians' office, a morgue and a linen chest. The eastern wing contains a woman's ward, large enough to hold a dozen cots, with direct communication to the woman's bathroom. This wing also contains an office for the superintendent of nurses, a private physician's office, a linen closet and other conveniences. The upper story is intended for the use of the resident physician and the necessary attendants. It is fitted up with four pleasant, comfortable bed-rooms and a bath-room. The rear wing, extending back from the main entrance, contains the operating-room, sterilizing department and instrument cases. Immediately across the hall is the emergency bathroom and patients' waiting-room. Still farther down the corridor is located the kitchen, pantry and dining-room, which is intended for the use of patients only, as the members of the staff have their culinary department in the service building near by. In the extreme southern end of this wing is the storage room for the electrical ambulances, and this room also contains a station for recharging the batteries; electricity for this purpose being brought from an electric circuit provided for the electric launches on the Grand Canal. In addition to the two electrical ambulances, a steam or gasolin motor ambulance will be ready in case of a possible failure of the electrical current. The building is provided with natural gas for heating purposes and for cooking when necessary for the patients. Water, gas and electricity are carried to every part of the hospital in the most approved manner. Dr. Roswell Park is the director, Dr. Vertner Kenerson. deputy director, and Dr. Alexander Allen the resident physician. To March 1. 504 cases have been treated on the grounds, only one of which proved fatal. These include all forms of sickness and accidents to workmen employed upon the construction work. In this connection it is well to note that the number of cases treated at the Omaha Exposition was about three thousand, while the history of the hospital at the World's Fair in Chicago gives a total of 11,602 medical and surgical cases treated, with 69 deaths.



— HOSPITAL, — PAN-AMERICAN EXPOSITION

CANADA.

Death of Nurse.—A nurse of the Montreal Civic Hospital, while attending to her duties in that institution, recently contracted measles and died. and the unsanitary conditions of the hospital are held accountable for her death.

Memorial Building.—The honorary secretary of the Hamilton City Hospital Board has decided to erect, at his own expense, a new $5000 out-door building for that institution, in memory of his wife, who took an active interest in the affairs of this hospital.

Private Wards.—At the next meeting of the Medico-Chirurgical Society of Montreal the question of private wards at the General Hospital will come up for discussion. There is much feeling among members of the profession of that city at the present on this question.

Antivaccination Bill.—There is a bill now before the Ontario legislature providing that persons having religious objections to vaccination shall have the option of declining to be vaccinated. The Civic Committee of the legislature will make a vigorous fight against the bill.

Notification of Tuberculosis.—The board of health of the Province of Quebec now requires that every householder in whose home a death from pulmonary tuberculosis occurs, shall notify the secretary of the board within forty-eight hours thereafter. The municipality must then disinfect any compartments of the house that may have become contaminated by the patient.

Vital Statistics.—Quebec's death-rate from tuberculosis is 1.99 per 1000; Ottawa, 3.12; Montreal, 2.87; Toronto, 2.41; Kingston, 2.17; London (Ont.), 2.67; Paris, 4.9; New York. 3.60. In 1898, while the birth-rate in Ontario was 20.4, that in the province of Quebec was 35.7; in 1899, it was 33.46. The birth-rate of the province of Quebec is higher than that of all countries except Germany.

Montreal's Scarlet Fever.—The scarlet fever epidemic in Montreal continues unabated. For six months, from September last, the cases reported to the health office have numbered 1046, while the deaths for that period from this disease number 222. In 1894 the city experienced a similar outbreak and the cases numbered 1915. Only 159 have been treated at the Civic Hospital, and of these 46 have died.

Addition to McGill.—Another large addition is to be made to the medical building of McGill University, Montreal, and will greatly increase the accommodation of the present buildings. It will be four stories in height, with a suitable basement and a lecture room, museums and chemical laboratories. The total cost of the proposed addition will be defrayed by Lady Strathcona and the Hon. Mrs. Howard.

Toronto Societies.—The organization of an academy of medicine is again being agitated in Toronto. The city has three societies, the Clinical, the Toronto Medical and the Pathological Society, and in a medical population of nearly 500, neither can muster an average attendance of two dozen. It is thought that an academy of medicine would prove instrumental in producing more original medical thought in the city.

Victorian Nurses.—The annual meeting of the Montreal branch of the Victorian Order of Nurses took place in that city last week. The nursing staff varied from seven to three during the year; 529 patients were cared for and 6751 visits, in addition to 150 night calls were made. The fees derived from patients amounted to $782.50. The staff at present consists of six nurses. Professor Adami was re-elected secretary.

Amalgamation of Schools.—In regard to the negotiations pending toward the amalgamation of Trinity Medical College with the Toronto School of Medicine, the corporation of Trinity does not consider the scheme as proposed feasible. The College is, however, favorable to amalgamation on broad lines. The rejected proposal was that the teaching staffs of the two schools be consolidated without any reduction at the present, and that a re-arrangement be made within two years.

Missionary Hospitals.—A cottage hospital at Sifton has been completed and equipped, by private aid, Lady Minto being particularly generous. A Montreal woman has offered to build a second one, and Dr. Reid, the medical missionary among the Doukhobors and Gallicians, urges that it be established at Ethelbert, twenty miles from Sifton. He says another medical missionary will be necessary to carry on the work connected with the two hospitals among these people of the Northwest Territories.

Treatment of Inebriates.—The prospects that the proposed bill for the treatment of inebriates will go through the Ontario House of Assembly this session appears very slim. The bill has the approval of the premier and other members of the government, and has been endorsed by the inspectors of prisons and the warden of the central prison, who is a medical man. Still the government hangs back and does not introduce the measure, and the session is now near its close. The promoters of the bill are very outspoken at the action of the government.

LONDON.

The Commission on Arsenical Poisoning.

The royal commission appointed to investigate the recent epidemic of arsenical poisoning has held several sittings. Dr. Winen, medical officer of health of Manchester, said that it was safe to say that not less than 2000 cases had been seen by medical men in Manchester. Professor Hope, medical officer of health for Liverpool, said that he was one of the members of a small subcommittee appointed by the Liverpool medical institution to investigate the extent of the poisoning epidemic. About 100 cases were tabulated by the subcommittee, which were all treated in public institutions. Arsenic was found in the viscera in some cases and there was no doubt that the poisoning was due to consumption of beer. There are sixty breweries or wholesale beer-selling firms in Liverpool. Samples of beer were taken from all these, and arsenic was found in those from twenty.

The Polyclinic.

The second annual report of the Medical Graduates College and Polyclinic shows that there is ample room for extensive development, both charitable and professional, on the lines which the Polyclinic has laid down for itself. The council has decided to appoint corresponding associates in all the important cities of America, and the continent. It is also contemplated to expedite the spread of clinical knowledge by some means of association with the other polyclinics of the world, so that each may be able to learn the more important work carried on in the others. The annual dinner will be held on May 22, at which the Right Hon. A. J. Balfour, M.P., will preside. The subcommittees appointed to investigate leprosy, yaws, climatology and tuberculosis have held repeated meetings, and laid the foundation of what is hoped will prove useful information on these subjects. A most valuable feature of the Polyclinic is the Hutchinson Museum. It contains the enormous collections of portraits of disease, mostly in water-colors, made by Mr. Jonathan Hutchinson. The greater number are original. With the exception of the splendid collection of the St. Louis Hospital, Paris, disease in the living has never been illustrated on such an extensive scale. This museum, which may be described as his life-work, Mr. Hutchinson has presented to the Polyclinic. At one time the portraits formed his private museum at Park Crescent, where he held weekly clinics, which were rendered exceedingly instructive by the systematic use of the drawings to illustrate the malady of each patient. No one has insisted so much on the value of clinical illustrations of disease for purposes of instruction and even for investigation of disease, and certainly no clinician of any age or any country has made such use of them. Skin diseases, which lend themselves most readily to pictorial illustration, form the greater part of the portraits, but almost every disease which shows external changes capable of illustration is represented.

For an annual subscription of $5 a doctor has the use of the library and museum, admission to the consultations and clinical demonstrations which are held daily, and to special courses of lectures, permission to use the laboratory for private research on payment of a small fee, a copy (post-free) of the college journal, facilities for attendance at affiliated hospitals, reports at a nominal cost on sputum, blood, urine or morbid growths, the right to recommend patients for gratuitous consultations, and title to vote at general meetings. There are now 674 members and subscribers. Special tutorial classes are held in laryngology, ophthalmology, otology, applied anatomy, Roentgen rays, neurology, and clinical microscopy. For these a fee is charged. American practitioners in considerable number have availed themselves of the institution. The great advantage of the Polyclinic is that it brings to a focus in one institution, for the benefit of qualified practitioners, the best clinical teaching of the metropolis. The ordinary hospitals are devoted to the training of students, and the practitioner can there only pick up a few crumbs and feels himself very much *de trop*. The weak point of the Polyclinic is that it has no hospital of its own—no beds. Hence the practical teaching is confined to out-patients. To remedy this the Polyclinic has been affiliated with a number of the special hospitals, and some of the smaller general hospitals—at which there are no medical schools. A doctor can attend any of these daily for a month on payment of $5.

FOREIGN.

Albert's Successor.—The chair of surgery at Vienna left vacant by the death of Professor Albert, has been bestowed upon the professor of surgery at Königsberg, A. von Eiselsberg, a pupil and assistant of Billroth in his day.

Suspension of "Vratch."—The publishers of the leading Russian medical weekly, *Vratch*, have appointed Dr. Vladislawleff editor to succeed the recently deceased founder and editor, Professor Manassein. The publication will continue, as heretofore, until the end of the year when it will be suspended, as expressly stipulated in his will.

New Journal.—Prof. Japp. Sinclair, of Owen's College, Manchester, and others who are connected with gynecological and obstetrical work in England, are arranging for the publication of a monthly journal devoted to these branches. There is not, at present, a gynecological and obstetrical journal in Great Britain, except the quarterly published by the British Gynecological Society. It is thought that such a publication is needed and that it will be well supported.

Smallpox Epidemic at Glasgow.—The smallpox epidemic is seriously threatening the prospects of the success of the forthcoming Glasgow International Exhibition. The epidemic is the greatest in Glasgow for thirty years. Since it broke out there have been over 1000 cases and 134 deaths. In most of the fatal cases the patients were aged from 40 to 50 and were unprotected by vaccination. There are 370 patients now in hospital. In the past week 130 fresh cases have been admitted, 90 dismissed and 10 deaths have occurred. Additional sanitary inspectors have been appointed and a house-to-house visitation is being made to discover unvaccinated persons and to impress on all the necessity of re-vaccination. In the past fortnight 77,562 have been vaccinated. Mild cases of the disease are often regarded as chicken-pox or spots due to indigestion, and give great trouble to the health department, as they are difficult to discover and produce numerous "contacts" which cannot be traced.

Abandoning the Old Trousseau.—This famous Paris hospital for children is to be demolished and a street opened through the site. Its place is to be taken by three hospitals in different parts of the city. One of these, the Bretonneau, in Montmartre, is already completed and the little patients were transferred to it on March 8. The hospital occupies a triangular lot between three streets and faces a large cemetery on one side. It has a capacity of 244 beds and the building alone costs about $1600 per bed; $60,000 had to be spent on the foundations, owing to the slope of the site. Jayle, in an article in the *Presse Médicale*, criticizes the arrangements unfavorably, pointing out that the promiscuous mingling of the children at the one entrance invites contagion. The pavilions for contagious diseases are all connected by a gallery, except the one for diphtheria. He regrets that the opportunity was not seized to separate the contagious from other diseases, and devote one hospital exclusively to surgical cases, instead of combining all the services in each hospital. The two others will be opened this month; one will be known as the new Trousseau.

Progress of the Plague.—The census of Bombay City just taken shows a population of 770,000—a decrease of over 50,000 as compared with the census of ten year ago. This decrease is mainly due to the exodus which has occurred during the last two months of the plague epidemic. In Mauritius, for the week ending February 28, there were 12 new cases, of which 8 were fatal. The total deaths from plague were 18. The increase of plague at Capetown caused considerable alarm and anxiety. Recently four new cases were reported in one day. Rats have been found in the dockyard, dying of plague. Inoculation of the inhabitants is proceeding. The government has issued regulations preventing natives from leaving the Cape district without a pass, prohibiting shipowners from landing natives at Table Bay without permission, and compelling natives to move their location. One morning five corpses of colored persons dead from plague were found and ten colored persons suffering from plague sent to the hospital. A large number of "contacts" and suspects have been placed in quarantine. A hotel in the center of the city, in a grossly insanitary condition, in which a case of plague occurred, has been closed.

Association News.

Railroad Rates for the June Meeting of the American Medical Association.—The Committee on Transportation reports that the Western Passenger Association has granted the following rate for transportation through its territory for the St. Paul meeting of the AMERICAN MEDICAL ASSOCIATION: One fare (regular) plus $2 for its round trip from all points in the Western Passenger Association territory more than 200 miles from St. Paul. From points within that radius, one fare and one-third for the round trip. Tickets from points 200 miles and over from St. Paul are to be sold May 27 to June 3 inclusive, and from points within 200 miles of St. Paul May 27 to June 4 inclusive. Tickets are good for return leaving St. Paul May 29 to June 15 inclusive. These rates will be given to the other passenger associations by the Western Association for ticketing through. The Committee will endeavor to obtain a better rate with a stop-off privilege and a longer time limit, H. L. E. JOHNSON, M.D., Chairman Committee on Transportation.

Correspondence.

Illustrations with Articles.

ADIN, CAL., March 7, 1901.

To the Editor:—Can not the contributors to THE JOURNAL be induced to include drawings in their articles, as Dr. Stricker has with his article in the March 2 number? The articles now being published on middle ear diseases would be of unstated benefit to hundreds of young physicians who do not and can not get to see clinics of that nature. If they were accompanied by illustrations showing the anatomical parts and the different steps in the operative work of those who frequently meet and deal with them successfully, we would be far better prepared to deal with those unfortunate ones who fall into our hands as general practitioners.

Our knowledge is very limited at best, on the study of medicine and surgery, and the only way a great many of us have to learn it is by reading, being so situated that we can not go to hospitals and watch every step in operative work. Therefore, I believe the more experienced would remove a great stumbling block if they would give us drawings with their papers. Most of our text-books illustrate very well, but omit that which sometimes would be of the greatest benefit. For instance, take a leading work on appendicitis, and the author illustrates the pathology of the condition, and tells us all about the operation, saying that if we do not properly pack the wound, when there is suppuration, we will have done a bad job, but he does not give one drawing to show what he calls a properly packed wound. This leaves us to our imagination to understand from what we read, what a properly sutured appendiceal stump is and a properly packed cavity as well.

Yours truly, C. M. TINSMAN, M.D.

Seasickness: A Sure Preventive.

PARK CITY, UTAH, March 19, 1901.

To the Editor:—Apropos of the treatment of seasickness, given in THE JOURNAL of March 16, I offer the following: None seem to have a sure remedy of seasickness, and the main reliance appears to rest on massive doses of nerve sedatives. It is a question with many, which they would sooner prefer; the after-effects of the medicines or the seasickness. Dr. Rawlin's remedy to "elevate all the limbs" is, for good reason, impracticable, when it is remembered that, on a rough sea, the position of the body is constantly changing. Dr. Brunton's bandage affords some relief; still, a better remedy is to plant the palms of the two hands on the abdomen and press hard toward the spinal column; but the good effect of either expedient is only temporary. If any one desires to experience *genuine* seasickness and to try his remedies for seasickness, he should cross the North Sea during winter; compared with the Atlantic Ocean, the waves of the North Sea are short and choppy. I there tried a simple contrivance, which I have never seen mentioned in articles on seasickness, and which served me excellently. I simply made a hammock from a blanket. It matters not how much the ship plunges or rolls, the hammock will practically stand still and keep the horizontal position. As long as I stayed in my hammock I experienced no seasickness, but if I left it when the sea was rough, nausea soon came on; as soon as I returned to the hammock the sensation of illness passed off. E. VIKO, M.D.

The Edinburgh Tradition and Clinical Instruction.

ELIZABETH, ILL., March 20, 1901.

To the Editor:—The editorial on p. 670 of THE JOURNAL for March 9, on "The Edinburgh Tradition and Clinical Instruction," was read with much interest. I appreciated more fully, perhaps its importance from having been instructed in an institution where the students, from the time they matriculate, are obliged to devote one-half of each day to clinical bedside instruction. This has been the practice, since its foundation in 1834, of the medical department of the Tulane University, New Orleans. The great Charity Hospital, so closely associated with this school, has given the faculty the opportunity to give bedside instruction. Since 1868 it has been the fixed regulation to divide the students into sections, each of which is taken in charge by a clinical professor and his chief of clinic. Bedside instruction is given each day in the hospital wards. Each student in a ward is assigned to a bed, and during the daily visits of a section to these wards, the individual student may at any time be called upon by the clinical professor to make a diagnosis, suggest treatment and offer a prognosis. This is done before the entire section, and the clinical professor is always there to make criticisms.

Since mention has been made in the editorial, calling attention to the superior methods used in several other medical schools, not of this country, the publication of this letter will point out that in our own country too, the "Edinburgh Tradition," in some schools at least, is also an established method

Yours truly, PHILIP ARNOLD, M.D.

Medical Interstate Reciprocity.

DETROIT, MICH., March 23, 1901.

To the Editor:—In the interest of the movement aiming at interstate reciprocity for the license to practice medicine, and at uniform medical legislation, on the basis of uniform medical education, the undersigned, as member of various committees, asks all secretaries of medical boards to be kind enough to favor him with information in regard to the present status within their jurisdiction. It is especially important to know: 1, whether the respective medical law contains the reciprocity clause; 2, whether the profession in the respective political division is sufficiently familiar with the subject matters; 3, whether any amendments have been added to the law, since May, 1900, or whether there exists any intention to amend the law. EMIL AMBERG, M.D.

270 Woodward Avenue.

The Yellow Fever in Port Limon, Costa Rica, in 1900. Reply to Surgeon-General Wyman, of the U. S. Marine-Hospital Service.

New Orleans, La., March 23, 1901.

To the Editor:—In reply to Surgeon-General Wyman's communication in The Journal of March 16 I will simply state that the fact that the representatives of the U. S. Marine-Hospital Service did not agree in the diagnosis of the representative of the Louisiana State Board of Health is no proof that Limon was not infected as early as July 17, 1900. The proof that the resident medical inspector of the Louisiana board was correct is that a few weeks later the natural evolution of the infection was so patent that it forced itself on the representatives of the service. Edmond Souchon, M.D.
President, Louisiana State Board of Health.

Married.

Sherman A. Allen, M.D., Imogene, Iowa, to Mrs. Isabel Linton, of Shenandoah, Iowa, March 13.

H. Stephen Hill, M.D., Seattle, Wash., to Miss Marie F. La Barraque, of San Francisco, at Seattle, March 4.

Carl Johnson Holman, M.D., St. Clair, Minn., to Eudora Madge Timmerman, M.D., of Mankato, Minn., March 14.

Deaths and Obituaries.

William F. Channing, M.D., University of Pennsylvania, Philadelphia, 1844, died in the Perry Hospital, Boston, March 19, aged 81. He lived in Providence, R. I., for a time after his graduation, and lately returned to Boston, after a residence for sixteen years in Pasadena, Cal., He published some of the first books on medical electricity, and was rather an inventor than a practitioner. The alarm telegraph, the hand receiver on the telephone and the marine railway were among his inventions.

Sherman A. Yule, M.D., Omaha Medical College, 1897, acting assistant surgeon, U .S. army, died from nephritis, in the Philippine Islands, March 4, aged 33. At the outbreak of the Spanish-American War he enlisted in the Funston Rifles and went to San Francisco. There he obtained his discharge in order to serve as an acting-assistant surgeon. He was on duty two years in Honolulu, and then was ordered to the Philippines.

James W. H. Lovejoy, M.D., Jefferson Medical College, Philadelphia, 1851, died at his home in Washington, D. C., March 18, aged 76. He served several times as president of the local medical society, was a member of the American Medical Association, one of the incorporators of the Garfield Hospital, and had been dean of the faculty of the Medical Department of Georgetown University.

Walter W. Medill, M.D., Medical College of Indiana, Indianapolis, 1889, a resident of Denver, Colo., for ten years, and a member of the American Medical Association, died at his home in Denver, March 14, from pneumonia, after an illness of one week.

George C. Venable, M.D., University of Pennsylvania, Philadelphia, 1850, for 40 years a practitioner of Charlotte County, Va., and for the past ten years a resident of Lynchburg, died at his home in that city, March 14, aged 73.

John K. Clark, M.D., Missouri Medical College, St. Louis, 1882, a member of the American Medical Association, and for many years a resident of Chillicothe, Mo., died at his home in Denver, Colo., March 9.

Rufus D. Sperry, M.D., Albany Medical College, who practiced for many years at Red Oak, Iowa, died at the home of his son in Omaha, after a ten years' illness from paralysis, March 11, aged 81.

George C. Chapman, M.D., Vanderbilt University, Nashville, Tenn., was struck by a falling telephone pole and killed during the cyclone that devastated Birmingham, Ala., March 25.

Stephen F. Gano, M.D., Transylvania University, Lexington, Ky., for many years a leading physician of Scott County, died at his home in Georgetown, March 23, aged 94.

William Watson, M.D., College of Physicians and Surgeons, Baltimore, Ind., 1886, died at his home in Allegheny, Pa., March 16, after a prolonged illness.

Jacob J. Smith, M.D., Jefferson Medical College, 1864, a well-known physician of La Crosse, Wis., dropped dead from heart disease, March 16, aged 63.

Charles L. Stoddard, M.D., Pennsylvania Medical College, Philadelphia, 1860, formerly of La Crosse, Wis., died at Colton, Cal., March 16, aged 65.

Henry Worthington, M.D., College of Physicians and Surgeons, New York, 1874, died at his residence in Los Angeles, Cal., March 12, aged 49.

J. Frederick Hedgcock, M.D., Southern Medical College, Atlanta, Ga., 1895, died from pneumonia, at his home in Lake City, Fla., March 13.

Charles H. Bowen, M.D., Columbian University, Washington, D. C., 1862, died at his home in Washington, D. C., March 12.

New Instrument.

An Effective Electric Trephine.

S. S. BISHOP, B.S., M.D.
CHICAGO.

The accompanying cut shows the exact size of two electric tubular saws, or trephines, the smaller of which is the one in common use in surgery of the nose and its connecting cavities. This instrument is capable of rendering excellent service where little work is to be done; but it has several serious faults which the writer has overcome in devising the larger trephine.

In removing a large and long spur from the nasal septum, it is necessary to trephine through the center of the spur, then above and below the center in lines parallel with the first section, if the small trephine is employed. If the spur is longer than the tube of the trephine, the instrument ceases to cut as soon as it penetrates the distance of its own length, for the portion of the spur that enters the tube fails to pass out of the counter-opening as fast as it enters the tube, and it prevents the saw from entering further. This necessitates withdrawing the trephine, removing the cut portion of the spur and readjusting the trephine for proceeding with the cutting. Meanwhile the field of operation is likely to become covered with blood, and more time is lost in removing this in order to see what tissues one is attacking.

The large trephine has a counter-opening as capacious as can be made without sacrificing the strength of the tube, so as to allow the contents to pass out as fast as they enter. It is much longer than the average spur, so that it would operate more satisfactorily than the small trephine, generally, even if the counter-opening were smaller. Its generous diameter renders it necessary to drive the instrument through the tissues fewer times in order to remove a given amount of growth.

In operating on the maxillary antrum the large trephine gives better results than the other. By passing the large instrument once into the antrum a canal of good size is obtained. Formerly I have passed the small one twice, and more times in some cases, before obtaining a sufficient opening for free drainage and efficient treatment. The large trephine is well adapted for opening the frontal sinus and the mastoid antrum.

Miscellany.

Calculus Weighing Twenty-two Ounces.—The *Indian Medical Gazette* reports a case of removal of a vesical calculus weighing twenty-two ounces from a man of 50. It consisted of uric acid and earthy phosphates.

The First Lithotomy in France.—The *Jour. de Méd.* relates that the physicians and surgeons of Paris besought King Louis XI to let them experiment on a criminal condemned to death, in order to learn the technique of removing calculi. The king consented, and the operation was performed in public, January, 1474, in the open air in a cemetery. After the surgeons had finished, the intestines were replaced, the wound sutured and the patient soon recovered.

Etiology of Malaria.—C. Schwalbe, of Los Angeles, opposes the mosquito theory of malarial infection and, in a brochure njust received, *Beitraege z. Malaria-Frage*, No. 1, calls attention to discrepancies in the researches to date. He suggests that no attempts have yet been made to inoculate persons with malaria on the open sea, for instance, absolutely free from suspicion of malarial infection from any other source. The failure of all efforts to determine the germ of infection in the air has forced scientists to evolve the mosquito theory, but no one will maintain that we are yet fully acquainted with the chemical composition of the air under all circumstances. The causal agent of malarial infection may yet be found to be a certain gas or gases in the atmosphere. The air close to the ground during the night has never yet been studied with all the appliances of modern science in malarial regions, to his knowledge. The scientist who will be able to enter upon this research under these conditions will be, he thinks, the fortunate one who will solve the problem of the etiology of malaria.

Varicocele in Army Surgical Practice.—Surgeon-General Sternberg has issued a circular, dated Feb. 27, 1901, inviting the attention of medical officers of the Army to the cure of varicocele by surgical intervention. The circular states that the rule laid down in Tripler's Manual should govern medical officers in the examination of recruits, viz., that a candidate for enlistment should be rejected if he has a varicocele which is larger than the sound testicle. If, however, upon a subsequent examination after enlistment a recruit is found to have a varicocele as large or larger than the sound testicle, and complaint is made of disability arising from it, this should not be considered a cause for discharge but for surgical treatment. A former decision of the War Department is cited to the effect that, except in case of a capital operation involving the risk of life, a soldier can not refuse to submit to medical treatment or surgical operation without subjecting himself to trial by court-martial for wilfully avoiding treatment the purpose of which is to enable him to perform the duties for which he enlisted. The circular publishes reports on operative procedures in such cases, at the General Hospital Presidio, San Francisco, by Lieut. Col. A. C. Girard, deputy surgeon-general; at the General Hospital, Washington Barracks, D. C., by Captain W. C. Borden, assistant surgeon, U. S. Army; at the U. S. Military Academy, West Point, N. Y., by Major J. M. Banister, surgeon, U. S. Army, and at Fort Snelling, Minn., by Captain A. E. Bradley, assistant surgeon, U. S. Army. The operation by incision over the pubes on the line of the inguinal canal has given uniformly better results in the hands of these surgeons than by incision through the scrotum. An aseptic field can be obtained with greater certainty above than below the pubes. Major Banister concludes that: 1. The operation for the radical cure of varicocele by the high incision with ligation a [illegible] cision of the veins is one of the most successful of surgi [illegible] cedures. 2. The operation is without risk to life in t [illegible] of a patient without disease of vital organs. 3. It [illegible] adapted to the military service. 4. No soldier otherwise [illegible] should be discharged from service on account of varicoce [illegible] It should be the duty of the medical department of the [illegible] to cure these cases, compelling compliance on the part of th [illegible] dier where objection is urged. Captain Borden is of opinion that a varicocele which produces disability and w [illegible] has originated in the service should not be considered a ca [illegible] for discharge, but should always be operated on, provided the operator is so situated that he can be reasonably sure of asepsis. The circular closes with an extract from a paper by Lieut.-Col. N. Senn, chief surgeon, U. S. Vols., chief of operating staff with the army in the field, from his work on the "Medico-Surgical Aspects of the Spanish-American War," in which the writer comments on the frequency of the existence of varicocele in young men who presented themselves for enlistment. In 9815 recruits, 2078 were affected with varicocele. His experience was to the effect that of itself the varicocele seldom gave rise to any noticeable disturbance, and that the patients who applied for treatment did so in consequence of nervous disturbances entirely separate and independent of the enlarged spermatic veins.

Necessity for a Closer Union of the Medical Profession in Missouri.—Efforts are being made by the American Medical Association to bring about a closer union of the regular medical societies in the United States. At the last meeting of the Association a committee was appointed to consider and recommend a plan for a thorough organization of the profession of this country. At the present time there are about thirteen hundred regular medical societies in the United States, most of which were organized, and are acting, independently of each other. The result is a lack of uniformity or concert of action among these bodies. In most of the states no systematic attempt has been made to organize local societies on a specific plan, the result being no uniformity of purpose or action in matters pertaining to the welfare of the profession in the state, consequently there can be no united effort made—political or otherwise. If the profession is to become a united body the beginning must be made in the county medical society. These must be organized in every county of the state and in harmonious relation to the state organization, and this in turn with the national organization. The difficulties which have beset the efforts to secure legislation for the regulation of the practice of the healing art in this state show that the opposition on the part of those whose objectionable practices would be prohibited by it are strongly organized and are powerful, and have with them the powerful influence of the lay press to which they are a source of profit. It has also shown that the profession must be so organized and united as to utilize its fullest power for the purpose of combatting this influence and it must not be content to leave to the efforts of a few courageous and self-sacrificing members the burden of defeating a strong opposition which is daily becoming more powerful and which is daily making it more difficult to secure adequate protective legislation. The tendency in the commercial world is to a closer union with a concentration of energy and the development of its greatest forces. Such a plan must be followed by the profession; it must be brought to a realization of the power and influence that it can wield through a close and a thoroughly organized union of its members, and such an organization must be effected, *it has become a necessity.* The politician hearkeneth eagerly to the strongest influence, be that what it may, and the ability to reward and the fear of retaliation are the [illegible]s that most frequently govern the actions of the averag [illegible] ian. In order for the profession to accomplish its [illegible] ts an [illegible] cure its greatest influence, a medical soci [illegible] ed in every county in the state to whic [illegible] practitioner in that county. Book Notices.

The Essentials of Practical Bacteriology. An Elementary Laboratory Book for Students and Practitioners. By H. J. Curtis, B. S., and M.D. (Lond.), F.R.C.S., Late Surgical Registrar, University College Hospital. Cloth. Pp. 291. Price, $2.50. New York and Bombay: Longmans, Green & Co. 1900.

This work will be found of practical value to the student or to the clinician who desires to refresh his memory in regard to details of investigation of certain subjects. Simple and reliable methods of staining are given, and the minutest detail is gone into in describing methods. The book is well illustrated.

Disinfection and Disinfectants. A Treatise on the Best Known Disinfectants, their Use in the Destruction of Disease Germs, with Special Instruction for their Application in the Commonly Recognized Infectious and Contagious Diseases. By H. M. Bracken, M.D., Professor of Materia Medica and Therapeutics, University of Minnesota. Cloth Pp. 85. Price, $1.00. Chicago: Trade Periodical Co. 1900.

This handy manual aims to present clearly the modern methods of disinfection which have come into common usage in recent years, especially since the introduction of formaldehyde and its use in various forms for disinfection. The author has had extended opportunity for practical tests and observations, as the secretary of the Minnesota State Board of Health, and the results of his study of methods employed as presented here are of value.

Introduction to the Study of Medicine. By G. H. Roger, Professor Extraordinary in the Faculty of Medicine of Paris. Authorized Translation by M. S. Gabriel, M.D., With Additions by the Author. Cloth. Pp. 545. Price, $5.00. New York: D. Appleton & Co. 1901.

The object of this work, which is a reproduction of a course of lectures delivered in 1897-98 at the University of Paris, is to give to those proposing to study medicine a comprehensive general outlook over the subject as a preliminary to more detailed study. The plan adopted by the author is first to show what the object of medicine is and the method of study and, after having explained why and how persons become sick, he considers the causes which tend to modify healthy conditions with the lesions and reactions which these determine, whether appreciable during life or after death. In this way he introduces pathologic physiology, pathologic anatomy and semeiology to the student. Therapeutics is only lightly touched upon, as might naturally be expected. While some parts of the book would seem to be suitable to advanced students as well as to the beginner, it is safe to say that the reading of the work will enable the beginning candidate for the medical degree to orient himself in the study of medicine far better than he could by his own selection out of the mass of medical literature. The average medical practitioner will also find the book instructive and serviceable. It is wholly up to date and practically authoritative. The translation appears to be fairly well made, and the printing and make-up of the book is excellent.

Societies.

COMING MEETINGS.

Tri-State Medical Society of Iowa, Illinois and Missouri, Keokuk, Ia., April 2-3, 1901.

Medical Association of the District of Columbia, Washington. D. C., April 2, 1901.

Tennessee State Medical Society, Nashville, April 9-11, 1901.

Florida Medical Association, Jacksonville, April 10, 1901.

Western Ophthalmological and Otolaryngological Association, Cincinnati, Ohio, April 11-12, 1901.

Medical Association of the State of Alabama, Selma, April 16, 1901.

Medical Society of the State of California, Sacramento, April 16-18, 1901.

South Carolina Medical Association, Florence, April 17, 1901.

Medical Association of Georgia, Augusta, April 17, 1901.

Louisiana State Medical Society, New Orleans, April 18-20, 1901.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 23-26, 1901.

Texas State Medical Association, Galveston, April 23, 1901.

American Association of Genito-Urinary Surgeons, Old Point Comfort, April 30, 1901.

Association of American Physicians, Washington, D. C., April 30, 1901.

South Carolina Medical Association.—The annual meeting of this Society will take place at Florence, April 17. Dr. James Evans of that city has been chosen to deliver the address of welcome.

Stevens County (Wash.) Medical Society.—The physicians of this County met recently and formed a medical society with Dr. Marcus R. Peck, Colville, president, and Dr. Matthew B. Grieve, Bossburg, secretary.

W. W. Keen Surgical Society.—The annual banquet of this Society was held recently in Philadelphia. Drs. W. W. Keen, James C. Wilson, Edward P. Davis, Hobart Amory Hare and W. M. L. Coplin responded to toasts.

San Joaquin Valley (Cal.) Medical Society.—The eleventh session of this Society was held in Fresno, March 13. The following officers were elected: Dr. Harry W. Taggart, Stockton, president; and Drs. Henry Hildreth, Delano, Nathaniel P. Duncan, Hanford, and Claeburne W. Evans, Modesto, vice-presidents.

Denver and Arapahoe Medical Society.—At its meeting March 12, the Society authorized the appointment of a committee to investigate and report on permanent headquarters with medical library, assembly hall and clubrooms. A committee was also appointed to watch the bills before the legislature. relating to the practice of medicine.

Newport (R. I.) Medical Society.—At a meeting of this Society, March 11, a proposed act was discussed under the provisions of which no physician or surgeon will be permitted to practice dental surgery. The Society entered a vigorous protest against this section, and a committee was appointed to take charge of the matter.

Society of Medical Jurisprudence.—This Society held its regular meeting, March 11, at the New York Academy of Medicine. Brevet Major-General N. Martin Curtis addressed the assembly, on "Capital Punishment—Unscientific and Futile." He maintained that it was an actual bar to the administration of justice owing to the prejudice of juries toward the death penalty.

Erie County (N.Y.) Medical Association.—This Association, which is an affiliated body with the New York State Medical Association, met March 11 and elected the following officers: Dr. DeLancey Rochester, Buffalo, president; Dr. William H. Jackson, Springville, vice-president; Dr. Arthur G. Bennett, Buffalo, secretary; Dr. Charles A. Wall, Buffalo, treasurer, and Dr Alvin A. Hubbell, Buffalo, trustee for three years.

JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY.

Meeting held March 18.

Dr. William H. Welch in the chair.

A Curious Form of Peritoneal Tuberculosis.

Dr. W. G. MacCallum presented an observation made in an autopsy. The peritoneal surface was smooth, with but little fluid, and embedded in it were numerous sessile nodules, many of which hung by pedicles in the peritoneal cavity. Some of the pedicles were long and slender, and entangled with their neighbors. Some were so deprived of blood as to be almost strangulated, and one of the nodules was free in the peritoneal cavity. Some of the pedicles have channels in their centers, lined with epithelium. These bodies are due to a traction on the peritoneal surface from the weight of the nodules. The latter have the characters of caseous masses and contain numerous tubercle bacilli. Definite miliary tubercles were not seen. These conditions are common in the perlsucht of animals, but rare in man. Only one similar case in the human subject has been described, by an Italian observer in 1867.

Dr. Wm. H. Welch said that doubtless many of the pedicles are due to traction on the serosa, but another explanation is possible. There is a form of peritonitis where a vascularized

Miscellany.

Calculus Weighing Twenty-two Ounces.—The *Indian Medical Gazette* reports a case of removal of a vesical calculus weighing twenty-two ounces from a man of 50. It consisted of uric acid and earthy phosphates.

The First Lithotomy in France.—The *Jour. de Méd.* relates that the physicians and surgeons of Paris besought King Louis XI to let them experiment on a criminal condemned to death, in order to learn the technique of removing calculi. The king consented, and the operation was performed in public, January, 1474, in the open air in a cemetery. After the surgeons had finished, the intestines were replaced, the wound sutured and the patient soon recovered.

Etiology of Malaria.—C. Schwalbe, of Los Angeles, opposes the mosquito theory of malarial infection and, in a brochure njust received, *Beitraege z. Malaria-Frage*, No. 1, calls attention to discrepancies in the researches to date. He suggests that no attempts have yet been made to inoculate persons with malaria on the open sea, for instance, absolutely free from suspicion of malarial infection from any other source. The failure of all efforts to determine the germ of infection in the air has forced scientists to evolve the mosquito theory, but no one will maintain that we are yet fully acquainted with the chemical composition of the air under all circumstances. The causal agent of malarial infection may yet be found to be a certain gas or gases in the atmosphere. The air close to the ground during the night has never yet been studied with all the appliances of modern science in malarial regions, to his knowledge. The scientist who will be able to enter upon this research under these conditions will be, he thinks, the fortunate one who will solve the problem of the etiology of malaria.

Varicocele in Army Surgical Practice.—Surgeon-General Sternberg has issued a circular, dated Feb. 27, 1901, inviting the attention of medical officers of the Army to the cure of varicocele by surgical intervention. The circular states that the rule laid down in Tripler's Manual should govern medical officers in the examination of recruits, viz., that a candidate for enlistment should be rejected if he has a varicocele which is larger than the sound testicle. If, however, upon a subsequent examination after enlistment a recruit is found to have a varicocele as large or larger than the sound testicle, and complaint is made of disability arising from it, this should not be considered a cause for discharge but for surgical treatment. A former decision of the War Department is cited to the effect that, except in case of a capital operation involving the risk of life, a soldier can not refuse to submit to medical treatment or surgical operation without subjecting himself to trial by court-martial for wilfully avoiding treatment the purpose of which is to enable him to perform the duties for which he enlisted. The circular publishes reports on operative procedures in such cases, at the General Hospital Presidio, San Francisco, by Lieut. Col. A. C. Girard, deputy surgeon-general; at the General Hospital, Washington Barracks, D. C., by Captain W. C. Borden, assistant surgeon, U. S. Army; at the U. S. Military Academy, West Point, N. Y., by Major J. M. Banister, surgeon, U. S. Army, and at Fort Snelling, Minn., by Captain A. E. Bradley, assistant surgeon, U. S. Army. The operation by incision over the pubes on the line of the inguinal canal has given uniformly better results in the hands of these surgeons than by incision through the scrotum. An aseptic field can be obtained with greater certainty above than below the pubes. Major Banister concludes that: 1. The operation for the radical cure of varicocele by the high incision with ligation and excision of the veins is one of the most successful of surgical procedures. 2. The operation is without risk to life in the case of a patient without disease of vital organs. 3. It is well adapted to the military service. 4. No soldier otherwise sound should be discharged from service on account of varicocele. 5. It should be the duty of the medical department of the army to cure these cases, compelling compliance on the part of the soldier where objection is urged. Captain Borden is of the opinion that a varicocele which produces disability and which has originated in the service should not be considered a cause for discharge, but should always be operated on, provided the operator is so situated that he can be reasonably sure of asepsis. The circular closes with an extract from a paper by Lieut.-Col. N. Senn, chief surgeon, U. S. Vols., chief of operating staff with the army in the field, from his work on the "Medico-Surgical Aspects of the Spanish-American War," in which the writer comments on the frequency of the existence of varicocele in young men who presented themselves for enlistment. In 9815 recruits, 2078 were affected with varicocele. His experience was to the effect that of itself the varicocele seldom gave rise to any noticeable disturbance, and that the patients who applied for treatment did so in consequence of nervous disturbances entirely separate and independent of the enlarged spermatic veins.

Necessity for a Closer Union of the Medical Profession in Missouri.—Efforts are being made by the AMERICAN MEDICAL ASSOCIATION to bring about a closer union of the regular medical societies in the United States. At the last meeting of the ASSOCIATION a committee was appointed to consider and recommend a plan for a thorough organization of the profession of this country. At the present time there are about thirteen hundred regular medical societies in the United States, most of which were organized, and are acting, independently of each other. The result is a lack of uniformity or concert of action among these bodies. In most of the states no systematic attempt has been made to organize local societies on a specific plan, the result being no uniformity of purpose or action in matters pertaining to the welfare of the profession in the state, consequently there can be no united effort made—political or otherwise. If the profession is to become a united body the beginning must be made in the county medical society. These must be organized in every county of the state and in harmonious relation to the state organization, and this in turn with the national organization. The difficulties which have beset the efforts to secure legislation for the regulation of the practice of the healing art in this state show that the opposition on the part of those whose objectionable practices would be prohibited by it are strongly organized and are powerful, and have with them the powerful influence of the lay press to which they are a source of profit. It has also shown that the profession must be so organized and united as to utilize its fullest power for the purpose of combatting this influence and it must not be content to leave to the efforts of a few courageous and self-sacrificing members the burden of defeating a strong opposition which is daily becoming more powerful and which is daily making it more difficult to secure adequate protective legislation. The tendency in the commercial world is to a closer union with a concentration of energy and the development of its greatest forces. Such a plan must be followed by the profession; it must be brought to a realization of the power and influence that it can wield through a close and a thoroughly organized union of its members, and such an organization must be effected, *it has become a necessity*. The politician hearkeneth eagerly to the strongest influence, be that what it may, and the ability to reward and the fear of retaliation are the motives that most frequently govern the actions of the average politician. In order for the profession to accomplish its best results and secure its greatest influence, a medical society must be organized in every county in the state to which should belong every regular practitioner in that county. Every member of the profession in the state must be interested in the general welfare of the profession and every county society must be brought into a close working relation with the state organization. . . . The office of president of the state association should not be regarded simply as an honorary position, but as the administrative and executive head of the profession in the state, and the occupant of that position should be chosen for his fitness for it, and should be a man of good executive ability, one who may be able to promote the organization of county societies and to weld them in a strong cohesive body. To obtain recognition for its demands the profession must make its influence felt—politically if need be—and it must act as an unit in all matter of interest to it. To do this it must organize, and that thoroughly.—*St. Louis Cour. of Med.*, March.

JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY.

Meeting held March 18.

Dr. William H. Welch in the chair.

A Curious Form of Peritoneal Tuberculosis.

Dr. W. G. MacCallum presented an observation made in an autopsy. The peritoneal surface was smooth, with but little fluid, and embedded in it were numerous sessile nodules, many of which hung by pedicles in the peritoneal cavity. Some of the pedicles were long and slender, and entangled with their neighbors. Some were so deprived of blood as to be almost strangulated, and one of the nodules was free in the peritoneal cavity. Some of the pedicles have channels in their centers, lined with epithelium. These bodies are due to a traction on the peritoneal surface from the weight of the nodules. The latter have the characters of caseous masses and contain numerous tubercle bacilli. Definite miliary tubercles were not seen. These conditions are common in the perlsucht of animals, but rare in man. Only one similar case in the human subject has been described, by an Italian observer in 1867.

Dr. Wm. H. Welch said that doubtless many of the pedicles are due to traction on the serosa, but another explanation is possible. There is a form of peritonitis where a vascularized membrane forms on the peritoneum, analogous, to that seen in pachymeningitis hemorrhagica, and some of the tubercles in Dr. MacCallum's case were doubtless formed in such a vascularized false membrane.

Lipomyoma of Uterus.

Dr. J. H. M. Knox had obtained this rare specimen, in an operation by Dr. Kelly, from a woman aged 62, the mother of thirteen children, the youngest being 24. She had had three miscarriages, the last twenty-six years before. The first symptoms occurred nine years ago, with a serous discharge lasting three weeks, but no pain. After some years the discharge reappeared, and again some weeks before the operation, which was done about sixteen months ago. There was never any pain, except on one occasion, when she had sharp pains like those of labor. The whole pelvis was filled with a firm mass extending to the umbilicus. There was nothing suggestive of anything more than an ordinary myoma until examination in the laboratory. Numerous oil globules could be pressed out of the mass, which was composed almost equally of muscular and fatty tissue. There was no fatty degeneration of the muscle fibers. Numerous eosinophilic cells were found grounded around the vessels, and a sessile polyp extended into the uterine cavity. The speaker reviewed the literature, in which very few such cases are to be found, and said that the specimen was of interest both because of its rarity and because the appearance may be due to misplaced embryologic elements.

Dr. Thos. S. Cullen, in 600 specimens of myoma in the hospital, had seen nothing like this. He said he had met at least three cases of malignant degeneration of a uterine myoma.

Dr. Wm. H. Welch thought the explanation given by Dr. Knox correct, and he had lately examined a myoma, sent by Dr. Geo. Ben Johnston, of Richmond, in which, mingled with the muscular elements, were true bone and much mucoid tissue.

Advances Made in Medical and Surgical Diagnosis by the Roentgen Method.

Dr. Charles Lester Leonard, of Philadelphia, presented a paper illustrated by lantern projections. The chief advantages are in fractures and calculi. In fracture without pain we can obtain more information than by manipulation. In impacted fracture diagnosis is impossible in any other way without great damage. It also aids greatly in securing coaptation and reducing. It may point out when reduction can be affected and when operation is necessary. The rule used to be to treat all suspected fractures as such; this is only justifiable now where we can not secure a Roentgen examination.

With this method we can absolutely detect or exclude all calculi. Early operation in pelvic or ureteral calculus, is of great advantage. Of 153 suspected cases examined, in 44 calculi were found; 25 of these were in the ureter. In one case several phleboliths in the veins of the broad ligament were shown in the plate.

Dr. H. A. Kelly said that the apparatus was indispensable and he had provided himself with one for private use and also for teaching purposes. In one case where he had removed a stone from the ureter, he was surprised to find that several more remained behind.

CHICAGO PATHOLOGICAL SOCIETY.

Meeting held March 11.

Dr. L. Hektoen, President.

Primitive Splenomegaly or Anemia Splenica.

Dr. Maximilian Herzog read a paper based on a study of the literature of this subject and on two cases in which Dr. M. L. Harris performed splenectomy. Particularly one of the two cases, both of which got well after the removal of the spleen, had been studied carefully as two years had elapsed since the operation. Before the operation there had been present in this case a marked diminution of the erythrocytes, a low color index and an absolute and relative reduction in the number of the leukocytes. The blood had improved very much since splenectomy, and there had developed a marked eosinophilia. An examination of the spleens removed showed a marked endothelial proliferation with enlargement of the blood lymph-spaces—pulp-spaces. Herzog stated that he had in vain sought for many destroyed blood-corpuscles inside of lymph-endothelia, a picture as it is, for instance, found in typhoid fever. Considering the fact that the blood condition had always improved in all cases of splenomegaly in which splenectomy had been performed provided the patient did not die from the operation, it appeared conclusive that the changes in the spleen must be looked upon as the primary factor in the disease. We therefore must look to the pathologic changes in the spleen as the cause of the blood destruction. From an examination of the two cases, as well as from a study of the literature, it appears that no evidence can be found that lymphatic endothelia destroy the blood by directly taking up blood-corpuscles. Herzog, therefore, advances the theory that lymphatic endothelia of the spleen and of lymph glands secrete an erythrolytic ferment, and in this manner destroy old and worthless blood-corpuscles. We have in splenomegaly an enormous endothelial proliferation, and probably in consequence an enormously increased production of the erythrolytic ferment, which, when present in such a large amount, destroys many healthy blood-corpuscles. If the spleen is removed, the source of the increased production of the erythrolytic enzyme is removed, and the blood improves rapidly and permanently.

Dr. W. A. Evans referred to a case of Dr. Ferguson's, in which there occurred petechial spots in the skin and where the spleen became smaller before death. He spoke of a case reported by Dr. Dalton, before the London Clinical Society, which was clinically one of splenic anemia, but at autopsy the enlargement of the spleen was discovered to depend on passive congestion, due to constriction by an anomalous colon.

Dr. Leo Loeb declined to accept the theory of an enzyme which destroys the red blood cells in the spleen.

Dr. E. H. Ochsner referred to a patient who clinically presented splenic anemia, and who improved for a time after the spleen was removed, but subsequently died. There were a few small tuberculous peritracheal glands found at autopsy. A possible infection in such cases must always be considered.

Dr. B. W. Sippy spoke of the similarity of these cases to the ordinary lymphatic pseudoleukemia as regards blood changes, general asthenia, etc., a similar enlargement of the spleen also being observed. In many cases of splenic anemia there is enlargement of the lymph glands, although it may be slight. In all cases the bone marrow has been converted into a fetal condition, like that found in many cases of pseudoleukemia lymphatica. He objects to the term "splenic anemia," and considers the one "splenic pseudoleukemia" to be the proper one. He believes the primary cause can not be positively located in the enlargement of the spleen. In the case described by him, the fibrous changes were much more marked than in Dr. Herzog's. This he thinks may depend upon the longer duration of the disease.

Dr. P. Keyes said that in the specimens of Dr. Herzog, the proliferation involves all the structures of the spleen, and such a condition can not be due to a primary proliferation of any one element, as the endothelium.

Dr. T. R. Crowder presented sections of an amyloid spleen with unusually distinct endothelial linings in the vascular spaces.

Dr. M. Herzog, in closing, said that he did not claim that there was proliferation of the endothelium alone, but that the increase in the endothelium was enormous, so much so that the condition had been mistaken for an endothelioma. Dalton's case had not been considered, as it was too indefinite. One reason for separating these cases from lymphatic pseudoleukemia is because they are curable by operation.

Pancreas Annulare.

Dr. Theo. Tieken exhibited a specimen of pancreas annulare, with resulting constriction of the duodenum so that a large fusiform sacculation of the latter had formed.

Blastomycosis.

Dr. H. M. Ricketts presented specimens of experimental general blastomycosis in the lung of a dog, produced by the intravenous inoculation of an organism obtained from a case of blastomycosis of the human skin.

MEDICAL SOCIETY OF RUSH MEDICAL COLLEGE.

Meeting held March 4.

Acute Ulcerative Endocarditis.

Dr. Theodore Tieken demonstrated a specimen of this condition, with a large perforation in the posterior segment of the aortic valve, and almost complete destruction of the anterior cusp by the ulcerative process. The valves were covered with large vegetations, many of which were calcified. The mitral valves were likewise studded with vegetations, which extended down the *chordæ tendineæ* as far as the apex of the papillary muscles. In addition to the ulcerative process on the aortic valves, an area of ulceration was found at the attachments of the bases of the semilunar valves which extended through the walls of the aorta, into the peri-aortic space. The heart was greatly hypertrophied and showed some interstitial fibroid changes. In the same case were found an annular pancreas and a sacculation of the duodenum, caused by the constriction of the intestinal lumen by a band of glandular substances, springing from the head of the pancreas in such a manner as to entirely encircle the lower part of the duodenum—descending portion, forming a true "pancreas annulare." The pancreas was normal in size and consistency, and cut with about normal resistance. The head measured 4 cm. in its vertical and 3.5 cm. in its transverse diameter. The annular portion measured 2.75 cm. at its narrowest portion and was 1 cm. in thickness. The ducts were in every way normal, and no abnormality was noticed in its vascular supply. In a hurried review of the literature he was able to find only four other cases reported to date. Although the patient had been under observation for nearly a year, no symptoms referring to the gastro-intestinal tract were ever manifested during life.

Obstruction of Popliteal Artery.

Dr. James B. Herrick presented a specimen showing obstruction at the bifurcation of the popliteal artery, produced by an embolus from the heart, the seat of chronic valvular and myocardial disease.

Suprarenal Tumor.

Dr. Herrick also showed a specimen of a suprarenal tumor where the tumor mass had invaded the inferior vena cava. This finding, which had been suspected during life, explained the early occurrence of an edema of the lower extremities, and had been one determining factor in deciding against operation for the removal of the kidney.

Lymphatic Leukemia.

Dr. Herrick also showed specimens of blood from six cases of lymphatic leukemia. He referred to the unknown etiology of the disease, to its clinical separation into acute and chronic varieties, to the resemblance of the former to an acute infection and of the latter to Hodgkin's disease, and also dwelt upon the variations in the blood picture as shown in his six cases. The statement so frequently made, that in lymphatic leukemia nucleated red corpuscles are very rare, was disproven in four of the six cases, three acute and one chronic, and specimens were exhibited showing numerous nucleated red blood-corpuscles. He spoke also of the great variety in the picture presented by the blood, according as the larger or smaller mononuclear forms prevailed in a given case. In one case, a rapidly acute one, there had been about 2 per cent. of myelocytes. Another interesting combination he had seen was that of a patient with carcinoma of the neck and jaw, with diffuse hyperplastic enlargement of the lymph glands and with the typical findings of a lymphatic leukemia, the blood counts never showing less than 100,000 leucocytes.

Interparietal and Intraparietal Aneurysms.

Dr. L. Hektoen presented several specimens illustrating interparietal and intraparietal extension into the heart of aneurysm of the beginning of the aorta, and of dissecting aneurysm of the heart. He described the spatium periaorticum cordis of Vestberg. The spatium periaorticum cordis is situated at the root of the aorta, and is covered by the reflection of the epicardium as it passes over the aorta behind the auricles and forms the floor of the sinus transversus pericardii. It is in this space that interparietal dissecting aneurysms of the heart most frequently are found by rupture or ulceration of its internal wall, the aorta. The specimens demonstrated illustrated the formation of dissecting aneurysm in this space as a consequence of ulcerative endocarditis of the aortic valves, and in consequence of the rupture into the space of small aneurysms in the beginning of the aorta developing primarily upon the basis of a syphilitic aortitis.

He also demonstrated a specimen of a large interparietal aneurysm in the right ventricle, originating in the sinus Valsalvæ of the aorta, and also an aneurysm originating in the left ventricle by two small openings, and forming a large cavity upon the lateral and posterior aspects of the left ventricle. The post-mortem in this case was made by Dr. Le Count, and the question as to the dissecting character of this aneurysm was discussed, the conclusion reached being that the aneurysm most likely originated in a suppurative process in the myocardium, and probably reached its present large extent in consequence of more or less dissection of the walls of the left ventricle.

Relief of Portal Obstruction.

Dr. H. Gideon Wells reported two cases illustrating relief of portal obstruction in hepatic cirrhosis by plastic peritonitis. In one the condition was found at autopsy, there having been no evidences of obstruction during life: the numerous adhesions of a chronic fibrous peritonitis were found largely replaced by thin-walled vessels, full of venous blood, up to the size of a crow's quill. The portal obstruction was due to an obstructive biliary cirrhosis from impaction of a calculus in the common bile-duct. The other case was that of a man with excessive ascites of about twenty months' duration, requiring frequent tapping, and due to alcoholic atrophic cirrhosis. A large umbilical hernia, resulting from the ascites, became strangulated and was reduced by operation. No attempt was made to establish a plastic peritonitis, and there was but little intra-abdominal manipulation, yet the ascites never recurred up to the time of the patient's death, eleven months later from carcinoma of the pharynx.

OMAHA (NEB.) MEDICAL SOCIETY.

Meeting held March 12.

Need for More Thorough Physical Examination of the Abdomen.

Dr. W. O. Bridges, in a paper on this subject, pointed out that the neglect of abdominal examination is a serious omission. He suggested a few of the important points of information, lost not only in diseases of the abdominal organs, but also in the failure to observe changes in abdominal organs which are a part of the pathology of constitutional diseases, and changes due to diseases of distant organs. We are too apt to draw conclusions from answers given and to fail to make painstaking examinations of organs so accessible. We are often asked why appendicitis, movable kidney and gastroptosis are more common now than formerly. The proper answer should be that they only seem more common because, hitherto, physicians have been too neglectful to investigate the abdomen. The literature on these conditions has been written, practically, in the last dozen years. The life insurance examination blank should require the same investigation as to the liver, spleen, kidneys, stomach and appendix as is now demanded for the heart and the lungs. The technique of examination is really very simple. Anesthesia will seldom be required. Inspection reveals some things. Distention or retraction, and prominence of veins should always be noticed. The character of the respiration, if abdominal, should be observed.

In many infectious diseases, particularly malarial and typhoid fevers, changes in the liver and the spleen are easily discoverable by palpation and percussion. These changes should be searched for daily, for the degree of change is a guide to the probable severity and duration of the disease. The persistence of a palpable spleen in typhoid fever, after cessation of fever, should warn of relapse or a sequel, and forbid the getting up of the patient, no matter how favorable everything else is. In malaria, specific treatment should be carried on until both spleen and liver are no longer palpable. Chronic diseases of the heart and lungs frequently produce great enlargement of the liver and spleen, and fluid in the abdominal cavity long before there is edema of the feet. In the anemias, the spleen should always be examined, for the grave cases only show enlargement of this organ. In many instances, affections of the abdominal organs produce effects elsewhere which are often very misleading. Precordial pain is often the result of pressure from a dilated stomach. Dyspnea, cyanosis, edema of the feet with coldness and numbness, irregularity of pulse, all can arise from enlargement of the liver or spleen, excessive tympanites, or an abdominal tumor. The pain of biliary colic is often referred to the right shoulder, and hepatitis, peri-hepatitis and abscess of the liver may simulate affections of the right pleura. A supposed pneumothorax has been proven to be hernia of the intestines through the diaphragm. Pus from an appendiceal abscess will sometimes burrow to the diaphragm and press it upward, simulating an empyema, or it may perforate the diaphragm and produce a purulent pleurisy. We are all familiar with melancholia and hypochondriasis as the result of disturbances of the stomach and liver. Dilatation of the stomach, gastroenteroptosis and movable kidney disturb greatly the nervous systems of women, and many a hysterical woman, whose affection is due to one of these conditions, travels the rounds without the real cause of her hysteria being detected. Reading Tolstoi's "Ivan Ilyitch" will give one a better idea of the relation of an abdominal organ to the nervous system than will a medical text-book, for the hero had a movable kidney, and the details of his life-history are painted far better than they could have been by the most celebrated neurologist.

A few illustrative cases were reported. Miss S., aged 22, had been a sufferer for months. She had cough, fever, sweats, emaciation, absence of respiratory function in the lower right lung. A diagnosis of pulmonary tuberculosis had been made. Close interrogation developed an early history of pain in the abdomen. An abdominal examination revealed a large appendiceal abscess, operated on later by Dr. Jonas, with slow but complete restoration to health.

Mrs. K., aged 34, gave a history of former and recent biliary colic without jaundice. She had fever, rapid pulse, nausea, vomiting and marked nervous symptoms. Two physicians in attendance had not made careful physical examination, and an extremely tender, movable egg-shaped tumor was found in the gall-bladder area. The diagnosis of empyema of the gall-cyst was proven by an operation made by Dr. Summers, which resulted in recovery.

Mrs. H., aged 30, was supposed to have passed through a malarial fever with slow convalescence. She had abdominal pain, nausea, vomiting, chills, fever, sweats, and jaundice; these had been present for several weeks. Examination showed a movable, tender tumor beneath the liver, the size of a small orange. It was diagnosed as a distended gall-bladder. Operation by Dr. Jonas proved the mass to be an empyema of the cyst, with calculi. Recovery took place.

Mr. H., aged 36, a hypochondriac of the worst kind, had been treated for years for dyspepsia, and had become an expert with a stomach-tube and was a superior dietist. After failure of treatment based on analyses of the stomach-contents, a more careful physical examination revealed a movable kidney of the third degree. This seemed to be the key to the situation, and Dr. Summers made a nephrorrhaphy which promised well for a time. Relapse, however, took place with the kidney fixed and later a surgeon in another city found many adhesions near the junction of the pylorus and duodenum, which he liberated. Again improvement followed for a short time. The latest report is that a third surgeon opened the gall-bladder and removed thirty to forty calculi, and the results of this are not yet known.

Crushing Injury.

Dr. Bridges briefly reported the case of a man who was caught between the bumpers of two cars, and suffered from crushing of the chest. His attention was called to the patient by reason of the fact that, during inspiration, there was recession of the right chest with expansion of the left; during expiration, expansion of the right chest and recession of the left.

WILLS' HOSPITAL OPHTHALMIC SOCIETY.

Meeting held in Philadelphia, March 11.

Dr. S. D. Risley in the chair.

Sympathetic Ophthalmitis.

Dr. Frank Fisher presented a case of sympathetic ophthalmitis coming on after a panophthalmitis which had followed a cataract extraction, the patient being 64 years of age. He laid special stress on the age at which the ophthalmitis had developed, and the long period of time elapsing between the condition and the cataract extraction.

Dr. William Zentmayer inquired whether it is not rare for the disease to evidence itself in cases in which there is panophthalmitis. In answer to Dr. John T. Krall's question whether the fundus of the sympathizing eye had been examined,

Dr. Fisher stated that when he saw the case the eye-ground had become invisible.

Dr. S. D. Risley asked whether subconjunctival injections of solutions of chlorid of sodium had ever been tried by any of the members of the staff.

Dr. Walter L. Pyle expressed belief that the occurrence of sympathetic inflammation after panophthalmitis depends on the amount of destruction of the globe. He believes that if there is decided scleral rupture and escape of most of the intraocular contents, sympathetic ophthalmitis is not likely to follow.

Dr. Charles A. Oliver said that all attempts to do useful iridectomy in such cases are futile, the iris-tissue being brittle and friable; while any obtained good results are rapidly lost. He has been successful in several instances, by either the Gritchett-Story operation or Tyrrell's method of drilling. He has never employed subconjunctival injections to any advantage, nor as yet made use of large doses of the alkalies, but if lymph formation and circulation are good the former method might be of assistance.

False Maculae.

Dr. George C. Harlan presented a case of false maculæ. The patient, a white man, 23 years of age, whose family and personal histories were negative, had squinted since childhood. He could use either eye. On Feb. 23, 1900, he was admitted to the hospital with an esotropia of 40 degrees, preferably fixing with the left eye. A tenotomy of the right internal rectus muscle, with an advancement of the corresponding external rectus, was done, leaving a residual squint of about 10 degrees. Two weeks later similar operations were performed on the left eye, with the result of an overcorrection of 10 degrees. On January 23, of this year, the perimeter showed 10 degrees of esotropia. The Maddox rod gave 20 degrees of crossed diplopia. At this time a tenotomy of the right external rectus muscle was done, allowing both eyes to fix centrally, but the crossed diplopia remained the same. One week later it was found that the esotropia of 10 degrees still persisted. There was no monocular polyopia. During fixation with both eyes a crossed diplopia of between 8 and 16 degrees, with a hypophoria of 0.5 to 2 degrees could be determined.

Extraction of Foreign Body from Vitreous.

Dr. C. Berens presented a case of successful extraction of foreign body from the vitreous chamber, with a resultant vision of 6/9 of normal. The patient, a man 38 years old, came to the hospital on Feb. 12, 1901, with the history of having been struck in the left eye one hour previously, by a chipping from a hammer. The external wound, which was vertical and 3 mm. in size, was situated in the cornea, 5 mm. from the nasal limbus. There was a corresponding wound in the iris. The pupil was 4 mm. in size, and central, and the iris reacted well. Under atropin the pupil enlarged to 8 mm. There were numerous vitreous opacities anteriorly, and some posteriorly. The details of the eyeground were slightly veiled. Far down and to the inside two semilunar areas, one of which at first showed a suspiciously bright point, could be seen. Under the Doctor's guidance, the senior resident surgeon enlarged the corneal wound down and in, did an iridectomy, and placed a magnet tip toward the side of the retinal laceration. Three unsuccessful attempts were made in this direction. Dr. Berens took the tip and inserted it twice, the second time down and out, recovering a piece of steel from that locality. Atropin was instilled and a bandage applied. On the next day there was slight reaction, but no pain. Two days later there was a moderate injection. At this time the patient could tell time on a watch, at one-half meter's distance. In eight days the eye was quiet, and vision equalled 6/20 of normal. The eyeground could be distinctly seen. Four days after this vision had arisen to 6/9 of normal, and the eye was quiet.

Double Coloboma.

Dr. C. A. Oliver exhibited a case of double coloboma of the iris, chorioid and optic nerve, with unusually small corneæ in an Italian girl of 16. As far as could be ascertained, there was no history of inheritance, nor were there any other signs of congenital malformation present. The colobomata were in their usual positions downward and slightly inward, those of the right eye being the larger. The characteristic curvilinear extension of the retinal vessels along the borders of the colobomatous areas could be plainly seen. The surfaces of the colobomata of the fundus, which were on a much deeper level than the rest of the eye-grounds, were quite ectatic in places. Refraction in the uninvolved macular regions was myopic and slightly astigmatic. Corrected vision equalled about two-thirds of normal. The visual fields showed defects corresponding with the fundus abnormalities. Both optic nerve heads were considerably enlarged. The retinæ in the colobomatous areas were visible as thin, almost transparent, membranes over and in which a few small vessels could be traced. The case was particularly interesting in the fact that, in spite of the apparent microphthalmus, the eyeballs were enormously lengthened in their anteroposterior diameters, giving high degrees of myopic refraction.

Spontaneous Extrusion of Iron from Eyeball.

Dr. Oliver also showed a patient from whom a chip of iron had been spontaneously extruded from the eyeball two years after its entrance into the crystalline lens, through the cornea and the iris. No reaction followed the expulsion of the foreign body. The lens itself had been studded with brilliant cholesterin crystals for more than a year.

Plastic Operation in Symblepharon.

Dr. C. Berens presented a case showing the recent effects of plastic operation for symblepharon, in which the conjunctiva of the upper lid had been adherent to the cornea over more than two-thirds of its surface, entire freedom of motion being restored to the globe.

Interstitial Keratitis

Dr. Oliver also gave a brief account of a case of interstitial keratitis occurring in the left eye of a man of 24, suffering from other stigmata of hereditary syphilis. He had treated and cured the patient's right eye for a similar attack of keratitis some six months previously. The point of interest in the case consisted in the fact that at the time of the patient's second admission to the hospital, some three weeks previously, the senior resident surgeon discovered a sloughing chancroid involving almost the entire foreskin of the patient's penis, necessitating excision of the sloughing part of the organ.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting held March 13.

Dr. George Erety Shoemaker in the chair.

Appendicitis and Cystic Ovary.

Dr. C. F. Nassau reported and presented specimens from a case of appendicitis and cystic ovary. The patient at one time had given the history of extra-uterine pregnancy, and a soft fluctuating mass had been found in the abdomen. An operation had been done and the uterus was found to have no supports. Later the patient suffered from uterine hemorrhages and the odor characteristic of carcinoma was present. The abdomen was again opened and a perforation of the appendix found. It was noticeable that seven weeks previous to the operation the right ovary had been healthy, but it had within that time undergone cystic degeneration and was several times the size of the normal organ.

Case of Appendicitis.

Dr. Mordecai Price reported a case that, a few days before, showed abdominal symptoms with great distention. The patient had taken enormous quantities of purgative medicines without avail. He was entirely unable to pass gas from the bowel. The patient died March 12, and at the autopsy a perforation of the appendix was found. The duodenum showed induration, and it might have been malignant in character. Another obstruction was in the region of the appendix, and thus the ilium was obstructed at both ends.

Postpartum Metastatic Panophthalmitis.

Dr. W. L. Pyle read a paper on this topic. He stated that this condition is rare in this country. The symptoms are usually manifested within the first fifteen days after delivery. Unilateral panophthalmitis is the most common, and this may occur after normal labor. Early ocular symptoms may begin by loss of vision, slight hypopyon, burning of the orbit, and finally an abscess forms followed by destruction of sight. The condition is essentially a septic one, and pyogenic microorganisms of different kinds have been discovered. The prognosis as to vision is hopeless. The treatment in the early stages consists in the instillations of atropin, and the application of hot compresses. Should an abscess form, it should be incised and drained carefully. The speaker detailed a case.

Dr. W. Reber said he had seen two cases of metastatic ophthalmia. He believes the usual seat of infection is in the choroid.

Obstetric Forceps.

Dr. R. C. Norris made some remarks on obstetric forceps employed by the general practitioner, and also on treatment of arrested position of the occiput. He thinks the employment of obstetric forceps during labor should be regarded as a major operation, and as of equal importance with an abdominal section. Absolute sterilization should be employed. The instruments should be placed preferably in boiling water for at least ten minutes. The hands should be sterilized, first with soap and water, and afterward with bichlorid solution. It is a mistake to think that sterilization can be made complete by simply laying the instruments in an antiseptic fluid. The vagina must be thoroughly scrubbed with soap and water, but a vaginal douche is not necessary unless a foul discharge has occurred. In forceps delivery rubber gloves should be employed. In all cases previous to the application of the forceps the position of the child must be determined. The head should be delivered through the vaginal ring, by means of the forceps. In 83 per cent. of the cases in which he had been called in consultation by general practitioners, the occiput was in a posterior position and failed to rotate anteriorly. One of the most common causes for this is incomplete flexion of the head. In some of these cases, external and internal manipulations are frequently insufficient to correct the faulty position. The reversed forceps operation should only be employed by a skilled obstetrician. When flexion is incomplete, backward rotation of the occiput is prone to occur, and in these cases forceps are useful as tractors. As rotators, he has more recently come to use the solid blade forceps of the Tucker pattern. Reversed forceps as rotators should be condemned.

Treatment of Placenta Previa.

Dr. Charles P. Noble read a paper entitled "The General Considerations of Treatment of Placenta Previa." He reviewed the literature on the subject. The mortality to the child is probably 50 per cent. and to the mother 5 per cent. The induction of premature labor is one of the most important plans of treatment. About the seventh month of gestation, the hemorrhage is severe and, if life is endangered. pregnancy may be terminated. Prior to this period, if the hemorrhage is recurrent in character the same procedure may be carried out. If the cervix is dilated the fingers may be inserted and a Barnes bag may be introduced and inflated by means of a syringe. It is always advisable to determine beforehand how much water the bag will hold. If hemorrhage is profound, version may be done. If the placenta is marginal, it may be left to Nature, as advised by Murphy. The rapidity of the fetal heart indicates the condition of the child. In these cases there is always increased liability to infection, and the parts should be sterilized as far as possible. Rubber gloves are to be recommended.

Cesarean Section in Placenta Previa.

Dr. George M. Boyd read a paper on "Indications for Cesarean Section in Placenta Previa." At the Philadelphia Lying-in Charity, placenta previa occurs in about 1 to 170 deliveries. The speaker would recommend that an examination under ether be made in order to determine the position of the fetus, as well as dilatation of the soft parts.

Dr. Barton Cooke Hirst said it is unnecessary to exaggerate the dangers of occipito-posterior positions, since this condition occurs in probably 25 per cent. of cases of labor, and of this number there are probably only 5 per cent. which failed to rotate. He has known of cases of this position in which forcible rotation of the head has not been followed by rotation of the body. In certain instances in which there has been damage to the pelvic floor, even without a tear, he has put in stitches to restore strength to the parts.

As to the treatment of placenta previa, he has met with twenty-four cases without having lost any. He thinks the usual mortality to the child is about 50 per cent. and to the mother 1 per cent. He does not consider Cesarean section necessary in these cases.

Dr. W. Reynolds Willson said that it is immaterial whether the blades of the forceps are applied to the sides of the child's head or not, in many cases. He could not agree with Dr. Norris in rotation by means of forceps, when the occiput is in a posterior position, because of the danger to the mother. As to the treatment of placenta previa, we should consider this condition in two classes: 1, those which might be called emergency cases; and 2, those which can be watched. In many of these cases it is unnecessary to resort to artificial dilatation, since this has been usually accomplished when the case is seen. Death generally results from shock in placenta previa.

Dr. Mordecai Price, as to the use of forceps, believes that these instruments do more harm than good to the child. He has never seen a Simpson forceps when slipped. As to the treatment of placenta previa, he believes that pregnancy should be terminated at once. If the placenta is centrally located, he believes in going straight through it. There is no hope through delay. To do Cesarean section is carrying it too far.

Dr. Stricker Coles believes that in cases of posterior positions of the occiput the most important thing to do is secure flexion.

Dr. J. M. Fisher said it is often difficult to make a diagnosis of the exact position of the fetus. He has seen only two cases in which the occiput failed to rotate anteriorly.

THE CHICAGO LARYNGOLOGICAL AND CLIMATOLOGICAL SOCIETY.

Meeting held February 28.

The President, Dr. Melville T. Hardie, in the chair.

Thyroid Tissue in Trachea.

Dr. Otto T. Freer exhibited a patient with typical thyroid tissue in the trachea. He had shown the patient three years previously.

Functional Tests of Hearing.

Dr. W. L. Ballenger referred to the controversies regarding the value of the functional tests in the diagnosis and prognosis of aural diseases, pointing out that much of the discussion has arisen on account of exceptions to the general rules, and that the continuous and increasing use of these tests by otologists is a fair indication of their recognized utility. He next laid down the physiologic facts of hearing, aural and bone conduction, and the principles underlying the tests, the range of normal hearing, the impairment in hearing low or high tones according as disease affects the conduction or perceptive apparatus respectively, and the difference between bone and air conduction in normal and in pathologic states. In the application of the tests constant practice is essential to estimate correctly their indications, hence the necessity of their routine utilization.

The various tests were reviewed. The most valuable physiologic methods are, he thinks, those with tuning-forks and whistles, and the best outfit for making a complete test of the range of hearing is the Bezold-Edelmann set. The Weber test he finds most reliable in unilateral middle ear disease, somewhat less so in labyrinthine disease, and least of all in chronic middle ear affections. The Schwalbach test was also described, and its modification, the Rinne, which, while not as reliable as the Weber, should always be used with the others. If in examination there is a correspondence between the results of the Weber, Schwalbach and Rinne tests, the latter is an additional proof of the pathologic condition present. Also the nonaccordance of the tests may lead to valuable deductions sometimes as to the locality of the disease. The tuning-fork best suited for the Rinne test is C^2 512, although one two octaves higher may be used. Unlike the Weber test, low forks are not satisfactory.

The author's personal experience with the Gelle test does not warrant him in expressing an opinion as to its value. According to Politzer, it is of value only in very severe deafness, and Ballenger thinks this is also true of Bing's test, No. 1. Bing's second test was also described, as well as the condition recently denominated spongifying of the labyrinth, but which was first described by Bezold twelve years ago.

In conclusion, Ballenger says that he has found many of these tests he describes of great value, though in many cases the information they give can also be obtained without their aid. In special cases they are of particular utility.

Dr. J. Holinger said that from the characteristic restriction of the function of the hip-joint we make the diagnosis of hip-joint disease. From restrictions of the function of the eye the oculist makes nearly 75 per cent. of his diagnoses. Hearing tests for diagnostic purposes are very recent. Those spoken of were mostly known before the seventies of the past century. But it was Professor Bezold who brought a system into those tests, and Bezold and Siebenmann proved by post-mortems that the system upon which they based their diagnosis was correct.

To test the hearing watches have been abandoned very largely, because they are not uniform. They can not, therefore, give results which allow comparison. Why not use the voice as long as we know its range is comparatively limited, and we always have it at our disposal? The essayist makes a distinct difference all through and gives some tests for middle ear disease; others for diseases of the labyrinth, etc. These tests vary considerably, owing to the condition of the middle ear or of the drum. Therefore, the examination with the funnel must precede. The differential diagnosis between disease of the Eustachian tube and an affection of the labyrinth or oval window can be made by comparing the results of all examinations with the normal. In an affection of the tube, if the drumhead is retracted and the middle ear comparatively emptied of air, we get three distinct symptoms by the tuning-fork tests, which are the same as in spongifying of the labyrinth. First we have negative Rinne; then an increase of bone conduction for the lower sounds; then a decided lack of hearing for the lower sounds by air conduction. The moment we inflate the middle ear through the catheter we create normal conditions in cases of affection of the tube. We have normal Rinne; we have normal bone conduction and normal lower sound limits. In spongifying of the labyrinth there is no change after inflation. Whenever we use these different tests we must ascertain first the condition of the drumhead. The test of Gelle was referred to by Dr. Ballenger. In the works of Bezold it did not find place. He dropped it for good reasons. The test is quite indefinite.

The essayist has told us that spongifying of the labyrinth occurs mostly at from 18 to 30 years of age. I would like to lay stress on the point that it *begins* at that time, continues for a longer or shorter period, and remains stationary thereafter. This is an important point to remember.

The three cardinal tests for spongifying of the labyrinth are negative Rinne, increase of bone conduction for A tuning-fork and the loss of the lower sound limit in normal condition of the drumhead.

DR. ALBERT H. ANDREWS said there are certain inaccuracies in most of the tests described. He finds the watch test of very little value, except in recording the changes which occur in the course of treatment or in the progress of ear disease. With regard to tuning-forks, each one has an individuality of its own. He has a number of forks that are C^2 512, but with one, with which he has made a great many experiments, the average relation in the normal ear between bone conduction and air conduction is in the relation of about five to six, bone conduction being about five-sixths of the time of air conduction. With another fork having the same number of vibrations per second, bone conduction is less than one-half that of air conduction.

He emphasized the point made by Dr. Ballenger, that in reporting functional tests it is necessary to determine and report the characteristics of the fork used in order that we may have a proper understanding of the tests given. As to functional tests with the voice, conversational tones range from about 80 to 256 vibrations a second, while the extreme limits of the human voice run from perhaps 64 to 1000. In testing the hearing ability for conversation, forks should be used ranging from 68 to 256.

DR. WILLIAM E. CASSELBERRY suggested that the essayist state what he considers the proper distance to hold the fork from the ear in testing air conduction. The results which will be obtained, especially with the Rinne test, will vary according to the distance at which the fork is held from the ear. In border-line cases a positive Rinne might become negative Rinne if the fork be held some distance from the meatus. The usual inexact instructions are to hold the fork opposite the meatus—it might be 1 cm. from the meatus, or many centimeters, and still be opposite.

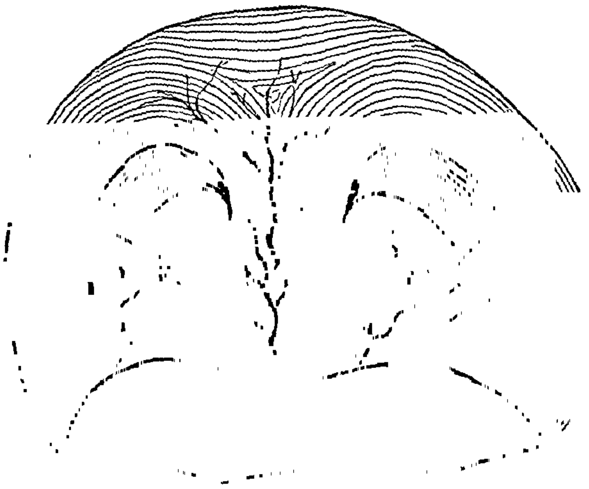

FIGURE 1.

DR. BALLENGER, closing, said, in reference to Dr. Holinger's remarks concerning the stapedius muscle, that he only mentioned the opinion of Rumbold, and not his own. As to the watch having practically been dropped as a test, he is not using it as much as formerly. It is of some value, however, as a test for ascertaining the progress that is being made during the course of treatment. Referring to the remark of Dr. Andrews that his fork shows a relationship on the average of five for bone conduction and six for air conduction, he said that such an instrument is poorly adapted for making the Weber, Rinne and Schwaback tests. The voice test is all right as a means of determining how well a patient hears conversation, but it is of comparatively little value in testing for diagnosis. It is of some value in testing the progress and course of the disease while under observation.

In reply to Dr. Casselberry, he said that his practice is to hold the fork near the ear and a little bit forward, say within one-quarter of an inch, care being exercised to avoid touching the hairs about the concha. The fork should be held so as to bring both prongs as near as possible. In this way the tone of the fork is heard at its maximum.

A Suggestion Concerning Uvulotomy.

DR. W. E. CASSELBERRY presented this topic, saying, in part: It is understood that chronic elongation of the uvula and relaxation of the soft palate are features of chronic pharyngitis, nasopharyngitis and rhinitis. It is in part secondary to these conditions and in part the conjoined effect of identical causes. The etiology includes recurrent acute attacks of rhinopharyngitis, contiguous tonsil disease, nasal stenosis, tobacco irritation and chronic pharyngitis incidental to digestive derangement and nutritional disorders such as rheumatism and gout. A complexity of causes is often operative in the same case.

The hypernutrition which affects the uvula and velum, like that of the posterior pharyngeal wall, has its origin in persistent hyperemia. Congestion leads to an exudation of leucocytes and a proliferation of the connective tissue cells of the submucosa. It excites hypersecretion and, in turn, the "hawking habit" serves, in part, to maintain congestion. Greville McDonald has called attention to the large number of glands imbedded on the posterior surface of the soft palate. In addition to the hyperplasia of the submucosa it is inferred that constant congestion of the subjacent muscular structures and their peripheral motor nerves, especially the levatores and tensores palati, leads to sluggishness of contractility and an ultimate fixation of the muscular fibers in their relaxed state. Moreover, the paresis in certain cases is attributable to pressure as from a very large adenoid growth and posterior enlargement of the inferior turbinated bodies.

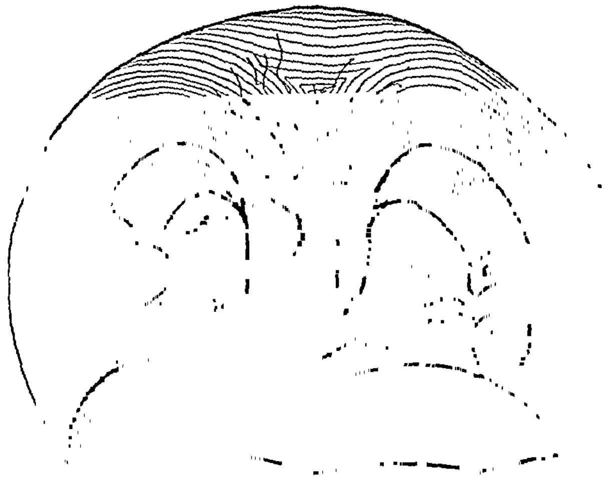

FIGURE 2.

Instead of hypernutrition the paretic palate may be actually thinner than normal, as in association with atrophic pharyngitis and in anemic emaciated states.

Regarding the uvula itself, at times the hypernutrition results only in increased length, its original diameter being approximately maintained, but in other cases, especially with chronic pharyngitis in plethoric persons, the uvula grows thick as well as long. The surplus growth near the tip may consist only of mucous membrane and connective tissue, but when much lengthened, and particularly in the thick variety, fibers of the relaxed and hypertrophied azygos uvulæ muscles are found well down in the elongated uvula, and require to be cut through in making an abscission.

Speech is plainly defective in extreme degrees of enfeebled palate resembling that of cleft-palate: *g* is substituted for *k*, as "gill" for "kill" and *d*, *b* and *s* are difficult to accentuate. The patient talks through his nose, the post-palatine space remaining too open. This defect should be distinguished from the "dead voice" of adenoid vegetations and nasal obstruction, although the two may be conjoined. Public speakers suffer from throat fatigue by reason of the unconscious extramuscular effort needed to raise the palate to a proper plane in speaking, thus conducing to chronic laryngitis. The singing voice is impaired in similar ways.

Snoring is another annoying symptom, caused by the vibration of the paretic velum while impinging on the base of the tongue. It is more common during oral respiration, but sometimes occurs with the mouth closed.

Treatment—He considered treatment in general and pointed out that, first or last, one resorts to amputation of a part of the uvula. The old method consists simply of a square amputation by scissors or uvulotome, an effort being made to slant the cut somewhat upward and backward. The stump which is left is broad, flat and firm at the end, instead of a rounded *tip of yielding consistency. The mucosa retracts, leaving a* bundle of sensitive muscular fibers exposed. The healing is prolonged, the swelling considerable and the after-pain severe. The stump may remain sensitive for several weeks. In one case the patient was conscious of it for months thereafter, complaining of the impression of something in his throat worse than before. These inconveniences may be largely avoided by the following simple expedient: The first step in the operation is practically the same as by the old method, except that the uvula is *grasped by the retaining forceps a trifle below the* exact point of desired abscission. The forceps are locked and the uvula abscised by scissors just above the forceps. The author's uvulotomy scissors answer especially well. The mucous membrane now retracts somewhat, and the next step is to make quickly a second abscission of the protruding bundle of muscular fibers. It is caught by serrated forceps drawn still further out from the retracted mucosa, and this time the muscle alone cut through. There is left a protruding edge of mucous membrane *which folds around the stump like a* circular flap, and in part covers its lower end. Thus cicatrization is hastened, the after-pain and swelling lessened, and the result is a more naturally rounded soft-tipped extremity. Fig. 1 represents the elongated uvula; Fig. 2, the stump after the first abscission with protruding muscular fibers; Fig. 3, grasping the muscular fibers and drawing them out from the retracting mucosa preparatory to the second abscission; Fig. 4, the circular flap folding around the stump after the second abscission.

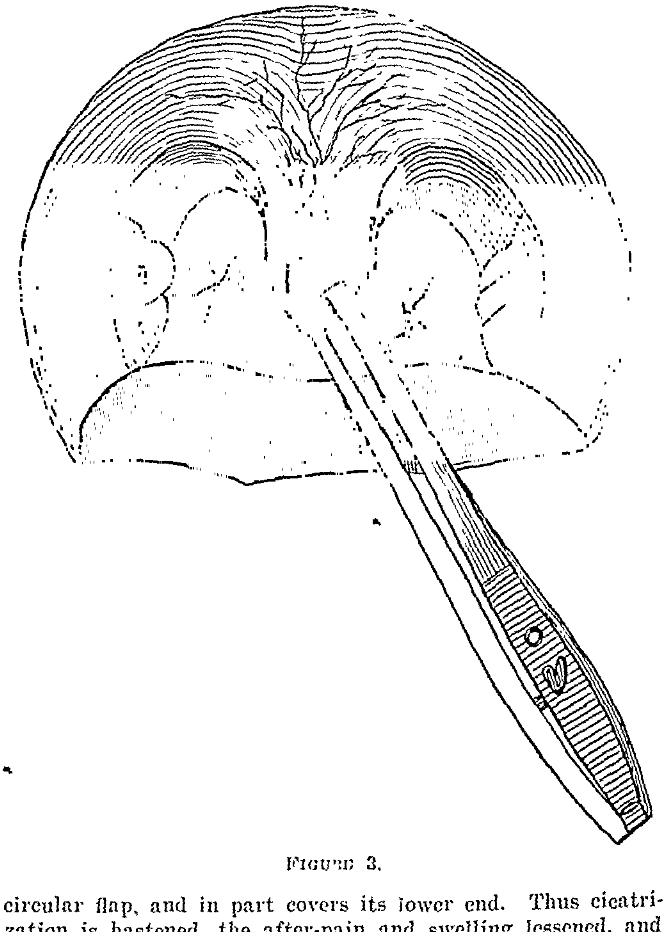

Figure 3.

Case of Nitrous Oxid and Ether Anesthesia for Tonsillotomy and Adenotomy.

Dr. W. E. Casselberry also reported a case, pointing out that the purpose of the combination is to hasten unconsciousness and thus, by lessening the *quantity of ether absorbed, by* from two to four ounces, to render ether anesthesia still safer, especially with regard to *elimination by the kidneys. For the* same reason, revival is quickened. Incidentally, time is saved, disagreeable sensations are obviated and the subsequent nausea minimized. The case reported showed *only the general feasi*bility of adapting the gas-ether combination by the open method to the *needs of the operation for conjoined adenoid* growth and hypertrophy of the tonsils.

Preliminary Report on Adrenalin.

Dr. W. E. Casselberry also presented this report, referring first to the extract of suprarenal gland and its action, saying that a medicament of such decided and much needed powers should possess a broad usefulness, but the inconveniences of the preparations heretofore supplied have served to limit its application. The most minute care is necessary to make and maintain the aqueous extract sterile. The development in it, *of organisms of putrefaction*, is hindered but not prevented by various antiseptics. It is both alleged and denied that uncertainty attends its administration by the stomach, but all agree that its use hypodermically is liable to result in abscesses. Hence efforts have been made from time to time to isolate its active principles.

He described adrenalin, a derivative, evidently an active principle, whose exact nature is not given. It is a *gray*, stable, amorphous powder, insoluble in strong alcohol, ether, *almond oil and albolene, and only sparingly soluble in water,* *about 1 to 5000. For practical use it is furnished in the form* of adrenalin chlorid dissolved in normal salt solution 1 to 1000, 1 to 5000 and 1 to 10,000, and from this he infers that the active principle acts as a base, uniting with acids to form salts. The adrenalin chlorid is more soluble in water, but is not a stable salt in dry form. The adrenalin chlorid solution is clear, colorless, odorless, sterile, stable if protected from light, and non-irritating to mucous membranes. When exposed to light for some days, or to heat, it undergoes some change which renders the solution pinkish in color and the strength less. When applied locally it exerts identically the *same vasoconstrictor influence* as the aqueous adrenal extract. Sprayed into the nostrils in the strength of 1 to 10,000, it produces at *once a visible change from turgidity* to compactness of the turbinated tissues, and a decided pallor of the mucous surfaces. *In the strength of 1 to 1000, or even 1 to* 5000, it has the same power to limit hemorrhage during operations upon spurs and deviations of the septum, and in pharyngeal operations. It is equally an aid in the treatment of epistaxis. It may be substituted for cocain in all cases in which an ischemic but not anesthetic effect is desired, e. g., to facilitate inspection of the deeper recesses of the nasal cavities and to increase access by cleansing solutions. Unlike cocain, it has little or no cerebral stimulant effect, exciting no desire for more beyond *the local relief afforded by it, hence* he thinks it is unlikely to lead to a habit.

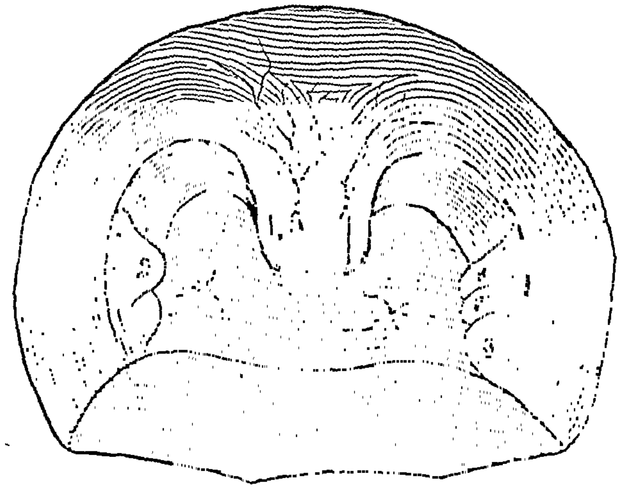

Figure 4.

Like cocain, its retractile effect on vascular tissue is *followed* by a reaction or subsequent turgescence, which varies in time and degree in accordance with the freedom of application, the extent of previous turgescence and other conditions. Thus, in acute rhinitis it has acted admirably in certain cases and seemed to aggravate others because of this reaction. It pales the congested mucosa in acute laryngitis and acute tracheitis, affording a corresponding temporary relief to the symptoms and hastening recovery. For this purpose he has shaken thoroughly together one-third aqueous solution of adrenalin chlorid, 1 to 1000, and two-thirds oil-vaselin, which mixture can be inhaled through the larynx in the form of spray. In like manner it should afford relief to those cases of asthma which are associated with bronchitis and vasomotor paresis, although he thinks there is little reason to expect an effect on cases of asthma in which spasm of the bronchioles is the major element. It is not chemically incompatible with the commonly used alkaline and antiseptic solutions, and it remains active in such solutions, at least for a time. The adrenalin may be rubbed up with vaselin, to form an ointment, or mixed with stearate of zinc, powdered starch or sugar-of-milk to make nasal or laryngeal insufflation powders. Its internal and hypodermic uses present fair fields for future observation.

Dr. Edwin Pynchon described his method of procedure in uvulotomy, as follows: Assuming that the uvula should be three-eighths of an inch long, he examines it and finds that it is three-quarters of an inch long. He then takes hold of its tip, with a suitable forceps, and stretches it until it is double that length, when, by using a curved shears such as is used by gynecologists for vesicovaginal fistula operations, and with the concave surface of the shears upward, he makes a curved cut, beginning in the middle and cutting backward and upward so the cut is finished up near the base of the uvula. Having done this he finds the muscular tissue shrinks more than does the mucous membrane, and the wind-up is that the muscular tissue or traumatic surface is entirely at the rear of the mucous membrane which covers and protects the stump of the uvula, so the annoyance incident to swallowing is thereby diminished. Eventually it heals at the size he desires it to be.

Dr. Moreau R. Brown said that it has been his custom to remove the uvula in a similar manner to that described by the essayist, and the operaton has satisfied both himself and the patients. In removing the uvula it is his aim to make the incision so that the cut surfaces will be to the back part of the stump. This is done with any ordinary curved-on-the-flat scissors. In some cases where the mucosa is lax it can be caught by the forceps and slipped up over the underlying muscular tissue. When both mucosa and muscular tissue can be divided, the mucosa will hang down and completely cover the muscular tissue. Occasionally he has reversed the procedure by catching the mucosa high up on the uvula and drawing it upward, then cutting through the tissues below the forceps.

Regarding adrenalin, he has been using it with considerable satisfaction. The preparations of adrenal gland have passed beyond the experimental stage and we know their value and efficacy and have for some time been anxious for the introduction of some such preparation as adrenalin.

Dr. E. Fletcher Ingals thought removal of the uvula by the method recommended by the essayist would be satisfactory, but the double cut seems unnecessary. He could not recall more than one case in the last twenty-five years where he would have gained anything by making a double cut. In that case the uvula was about as thick as one's little finger, and the patient had a very sore stump for several days. The best method, in his experience, is to remove the uvula with the ordinary polypus snare. The uvula is caught exactly at the point where we want to cut it, and with a single closing of the fingers it is removed. If thought desirable to cut the muscular tissue, higher up, this could be done in cases where the mucous membrane is loose, by simply catching the uvula lightly with the wire first, then lifting up the mucous membrane an eighth of an inch and then closing the wire loop.

In most cases we will note that when we have cut it off, the raw end of the stump is not more than half the diameter of the whole uvula. He has never seen any inconvenience from operating in this way, except possibly in the one case to which he referred. The hemorrhage from this method of operating is much less than when scissors are employed, and the tissues may be cut with much more accuracy than when they have been drawn down by forceps.

Dr. G. P. Head said he had found, in operating on the uvula, that unless he wished to do as Dr. Pynchon recommended, that is, put the uvula on such a stretch as to amputate a large portion of the mucous membrane, with the ordinary curved scissors it was difficult to engage it in the first snip. In looking around for an instrument that was not a uvulotome, he found a useful one in Hanks's trachelorrhaphy scissors, which is notched at the end, and curved a little on the edge as well as on the flap. With it he gets the advantage spoken of by Dr. Ingals in the use of the snare, in that when he engages the uvula he does not pull it down to any extent, but simply holds it lightly with forceps, the notch at the extremities of the blades holding the uvula firmly while he makes the snip. In this way we can get what portion we want without putting the mucous membrane on a stretch. These scissors are unexcelled as an instrument for removing tonsils which are too small for the tonsillotome.

Dr. J. Homer Coulter asked whether the only object in giving the ether is to obtain additional time?

Dr. Casselberry, closing the discussion, said "yes, nitrous oxid is supplemented by ether to gain additional time for operating." In elucidating his method of uvulotomy, he said that his instrument is a pair of long-handled, slightly curved scissors, which he had made for the purpose. One blade has a cross-bar at the end. This curve facilitates the upward and backward slant, and the cross-bar keeps the uvula from slipping out. He has not had serious hemorrhage following uvulotomy, but in one or two cases a slight application of the cautery point seemed best to stop the bleeding without annoying delay. Should an active hemorrhage occur inside the flap of mucous membrane, it might be difficult to control it by mere cauterization, and this might be some objection to the method. Persistent bleeding, however, from uvulotomy, by his method is exceedingly rare, and if it should occur it could be controlled by compression. or one could snip off some of the mucous membane that had been folded around the stump. With reference to a second cut, he has not found it objectionable, if made very quickly after the first one; the patient does not appreciate that it is more than a continuation of the one cut, but after having made the first one, he often takes a moment to apply cocain afresh to the raw surface, and then makes the second. In regard to snaring the thick type of uvula, to get the snare on the uvula in exactly the right place, especially with patients disposed to gag easily, would require a high degree of expertness.

With respect to the reaction following the use of adrenalin and the alleged greater liability to hemorrhage than would otherwise result from operations done without its influence, in nasal operations for the removal of excrescences, correction of deviations of the septum, etc., it is his custom to pack antiseptically, immediately after the operation, hence it does not matter whether there is greater liability to bleed or not. In pharyngeal operations he has not used adrenalin nor aqueous extract of adrenal gland. on account of the tendency to greater hemorrhage after its use. As a rule, we can get along just as well without it in pharyngeal operations.

Dr. Edwin Pynchon called the attention of the Society to the use of a strong solution of nitrate of silver—25 per cent.—to prevent hemorrhage after uvulotomy. It has been his custom to apply it in this strength, and he has always found it very satisfactory.

Notes on Adrenalin and Adrenalin Chlorid.

Dr. E. Fletcher Ingals read a paper on this subject. It will be printed in The Journal.

Officers.

The following officers were elected for the present year: President, Dr. Wm. E. Casselberry; secretary and treasurer, Dr. John Edwin Rhodes; council, Drs. T. Melville Hardie, Dr. J. Holinger, and O. J. Stein.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Gonorrhea.

The varieties of urethritis may be classified as follows: Acute and chronic. 1. Simple: *a*, toxic; *b*, traumatic. 2. Specific, due to the gonococcus. Attention will be called to the treatment of the specific form only. It consists of both local and internal medication. Lydston advises, as abortive treatment, removal, as far as possible, of the virulent germs which have been deposited on the surface of the mucous membrane; a prolonged and thorough irrigation of the anterior urethra with a solution of potassium permanganate, 1 to 10,000 to 1 to 5000. During this treatment he advises internal medication by the administration of alkalies. As to the general management of the disease. he emphasizes the importance of rest—physical and sexual—in bed. Next in importance to rest is attention to the diet, in order to limit the elimination of irritative products by the urine. A vegetable diet or a bread and milk diet is preferable, avoiding asparagus and tomatoes.

LOCAL TREATMENT.

A solution of hydrargyri bichloridum, 1 to 30,000 to 1 to 15,000, in combination with a small amount of glycerin, is recommended.

AS AN ANODYNE INJECTION.

℞.	Atropinæ sulphatis	gr. i		06
	Bismuthi subnit	ʒiii	12	
	Mucil. acaciæ			
	Aq. destil., āā	℥ii	64	

M. Sig.: Shake well and inject three times daily; or

℞.	Tinct. opii deod	ʒiss	6	
	Bismuthi subnit	ʒiii	12	
	Mucil. acaciæ			
	Aq. destil., āā	℥ii	64	

M. Sig.: Shake well and inject three times daily.

AS AN ASTRINGENT INJECTION.

℞.	Zinci Sulphatis	gr. x		66
	Morph. sulph	gr. viii		50
	Glycerini	ʒi	4	
	Aquæ rosæ	℥iii	96	

M. Sig.: As an injection; *or*

℞.	Zinci sulpho-carbol	gr. xii		72
	Glycerini	ʒi	4	
	Aquæ rosæ	℥iii	96	

M. Sig.: As an injection.

A VEGETABLE ASTRINGENT.

℞.	Hydrastis muriatis	gr. viii		5
	Ext. hamamelidis flu	ʒi	4	
	Glycerini	℥i	32	
	Aq. destil q. s. ad	℥iv	128	

M. Sig.: As an injection.

The following may be of service as an astringent:

℞.	Bismuthi subgallati	ʒiss	6	
	Zinci sulphatis	gr. xv	1	
	Aquæ calcis	℥vi	192	

M. Sig.: Use as an injection three times a day, after urinating.

The following is the general outline of treatment used by Dr. Henry J. Scherck. as given in the *Ther. Gazette:* The urethra is first carefully washed with lukewarm water, followed by an injection of the following:

℞.	Protargol	gr. xx	1	33
	Aq. destil. q. s. ad	℥iv	128	

M. Sig.: As an injection twice or three times a day.

The solution, whatever it may be, should be introduced gently into the canal with a three-ounce, hard-rubber syringe. The solution should be allowed to remain for five minutes, the patient closing the meatus by pressure of the finger. Instead of protargol, Dr. Scherck sometimes employs mercurol in 2 per cent. solution, or Credé's silver in 1 per cent. solution. After the solution has been allowed to escape, a two-gallon irrigator filled with a 1 to 1000 solution of potassium permanganate, at a temperature of 120 F., is irrigated into the canal, the irrigation being raised to a sufficient height to cause the pressure to distend the canal without overcoming the sphincter muscle. The entire amount of the permanganate solution is used in this way. The strength of this solution should be increased from day to day until about 1 in 500 is attained.

As to internal medication, the main object is: 1, to keep the urine from causing irritation, and this may be accomplished by alkaline treatment; 2, to render the urine aseptic and germicidal, by the use of the following combination:

℞.	Cystogen	gr. v		33
	Ol. santoli	m. x		

M. Ft. cap. No. i. Sig.: One such capsule every four hours.

Cystogen is said to be of similar composition to urotropin. which is a compound produced by the action of formaldehyde on ammonia.

Careful attention to diet is necessary, with care to avoid such articles as would tend to congest the genito-urinary tract or increase the acidity of the urine, or in any way increase the irritation to the mucous membranes. He advises, in the main, the same line of treatment in chronic as in the acute cases.

SILVER SALTS IN ACUTE GONORRHEA.

Youmans (*Med. Standard)* states that the urethra should be irrigated twice daily with a 1 to 4000 solution of potassium permanganate. If streptococci are present in the discharge, a 1 to 20,000 bichlorid solution should be added to this. The temperature of the solution used for injection should be 110 F., gradually increased to 120. If the disease is in the posterior urethra the fluid is allowed to flow into the bladder by hydrostatic pressure, after washing out the anterior portion of the urethra. After each irrigation, the following injections are used:

℞.	Argonin	ʒii	8	
	Aq. destil. q. s. ad	℥iv	128	

M. Sig.: As an injection; or

℞.	Protargol	gr. xl	2	6
	Aq. destil. q. s. ad	℥iv	128	

M. Sig.: Use as an injection after each irrigation, and retain ten minutes.

W. W. Wilson *(Buffalo Med. Jour.)* states that argonin is by far the best. He uses it as follows:

℞.	Argonin	gr. xl	2	66
	Aq. destil. q. s. ad	℥iv	128	

M. Sig.: Use as an injection four times a day. The solution should be retained ten minutes each time.

Argonin is a compound of silver—4 per cent. It has the disadvantage of not being soluble in cold water. It should be kept in dark bottles, as it is easily decomposed by light.

ARGENTAMIN IN GONORRHEA.

This preparation has been employed with good success in gonorrhea. It is a solution of silver phosphate in aqueous solution of ethylendiamin. It is an antiseptic which does not precipitate albumin, is alkaline in reaction, and can be used in the strength of 1 to 3000. For conjunctival application it can be used in 5 per cent. strength.

IN HIGH-GRADE INFLAMMATIONS.

The following is sometimes recommended to subdue the inflammation:

℞.	Morphinæ sulphatis	gr. ii		12
	Liquoris plumbi subacetat. q. s. ad	℥vi	192	

M. Sig.: Inject four or five times daily. A warm solution is better.

Duguaire (*Sem. Med.)* very highly recommends the following as an injection:

℞.	Ol. gaultheriæ	gr. xv	1	
	Bismuthi subnit	ʒv	20	
	Petrolati (liquid)	℥iii	96	

M. Sig.: Use as an injection three times daily, with a syringe, the nozzle of which has a soft and extra wide canula.

POTASSIUM PERMANGANATE AS AN INJECTION.

℞.	Potassii permanganatis	gr. 1/4 to 1/2		015-03
	Sodii chloridi	gr. xv	1	
	Aq. destil	℥vi	192	

M. Sig.: Inject four or five times daily.

In some cases where there is chronic inflammation of the bulbous urethra, Lydston advises the following, introduced through the endoscopic tube:

℞.	Iodoformi	ʒiv	16	
	Tinct. benzoin comp.			
	Balsami peruvianæ, āā	℥i	32	

'M. Sig.: Apply through the endoscopic tube.

METHYLENE BLUE IN GONORRHEA.

Dr. J. A. Oneill *(Med Record)* states that he can quickly effect a cure by the administration of methylene blue as follows:

℞.	Methylene blue	gr. i		06
	Olei myristicæ	m. i		*06*
	Olei santoli	m. ii		12

M. Ft. capsula No. i. Sig.: One such capsule four times a day.

By giving four grains of methylene blue daily, he states, there is always enough of it in the urine to kill all the germs with which it comes in contact. It should not be used continuously longer than ten days at a time.

ICHTHYOL IN THE GONORRHEA OF WOMEN.

Dr. J. G. Clark *(Am. Jour. of the Med. Sci.)* maintains that absolute rest in the acute stages is of the greatest importance. As to treatment, he regards ichthyol as the most valuable preparation, because it is non-irritating and is very effective in alleviating pain and reducing the inflammation, and its use is not followed by the disagreeable results sometimes noted after the use of more irritant remedies. He uses it in solutions of 1 to 5 per cent. strength, injected into the urethra.

Complications of Gonorrhea.

EPIDIDYMITIS AND ORCHITIS.

Rest in bed is the important treatment when there is acute inflammation of the testis. Stimulation to the urethra by means of injections should be stopped. Local applications of poultices of linseed or tobacco are strongly recommended by many specialists. The administration of saline cathartics and alkaline diuretics is necessary. The use of opiates to control the pain is sometimes imperative. Where it is inconvenient to apply poultices, Lydston recommends the following:

℞.	Menthol	gr. xl	2	66
	Ext. belladonnæ	gr. xx	1	33
	Ext. *aconiti*	gr. x		66
	Lanolini q. s. ad	℥ii	64	

M. Sig.: Spread on lint and continuously apply to the testicle; *or*

℞	Methyl salicylatis	ʒiii	12	
	Ext. belladonnæ	ʒi	4	
	Adifis	℥i	32	

M. Sig.: Apply locally to the testicle.

GONORRHEAL OPHTHALMIA.

It is not unusual for the general practitioner to make a mistake in his diagnosis of gonorrheal ophthalmia. He may attribute the purulent discharge to other causes than gonorrheal infection; on the other hand he is very liable to mistake a mucus for purulent discharge, and thus, by use of the silver salts, create a diseased condition in an otherwise healthy organ. Especially may this be the case following the use of silver nitrate solutions. In true gonorrheal infection of the eye the following seems to be the favorite of most oculists, because it is non-irritating:

℞.	Protargol	gr. xx-xxv	1	33-1.66
	Aq. destil. q. s. ad	℥i	32	

M. Sig.: Drop into the eye twice daily.

Protargol is a proteid compound containing 8.3 per cent. silver. It is freely soluble in cold water and is stable.

GONORRHEAL ARTHRITIS.

Dr. C. A. Porter *(Boston Med. and Surg. Jour.)* says that drug treatment does not yield the proper results. He has obtained his best results from the continuous use of ice-bags, or dry heat, preferably at a temperature of 250 to 400 F. The actual cautery is the best counterirritant and frequently relieves the pain. After two or three weeks, when the acute process has subsided, resort to massage and movement of the joint should be had.

Medicolegal.

Issuance of but One Temporary Certificate Authorized.—A statutory provision that one member of a board of medical examiners may give a temporary certificate entitling the holder to practice medicine until the next meeting of the board, the Supreme Court of Texas holds, in the case of Peterson vs. Seagraves, will confer on an individual member of the board authority to issue but one temporary certificate to a person. An express prohibition of the issuance of more than one temporary certificate or license to the same person it deems unnecessary. Nor does it consider that the fact that the laws regulating the practice of dentistry and pharmacy in the state may contain provisions expressly forbidding the issuance of more than one temporary certificate can be taken to determine the construction of a practice act existing before those laws were passed.

Change of Residence Requires New County License.—The Appellate Court of Indiana says, in the case of Mayfield vs. Nale, that the statute of that state is plain that, if a physician changes his residence from one county to another, he must obtain a new license in the county where he proposes to reside. This is a condition precedent to his right to practice in that county, and it is made unlawful for him to practice in such county without such license. In consequence, he can not maintain an action for medical services rendered in a county, after moving thereto, without first having procured the requisite license. That he may subsequently comply with the law will not enable him to recover for services rendered in such county prior to obtaining a license therein. Whether the law that makes possible such a defense where competent professional services have actually been rendered is a wise one, it is held, is not for the courts to say.

Conversations in Presence of Third Parties.—The Appellate Court of Indiana holds, in the case of the Masons' Union Life Insurance Association vs. Brockman, that as to what a witness who made his headquarters at a physician's office for a couple of weeks heard the physician and a patient say was not privileged, as to such witness, but he could testify thereto. For example, if the patient was being treated for the drink habit, and the witness knew it, either from his own knowledge or from what he heard the patient and his physician say when they were in each other's presence, it was competent for him to so testify. As to what weight the evidence might have with the jury was not a question with the court. It is the rule, the court adds, that, if statements are made in the presence and hearing of a person affecting his rights, and under such circumstances as call for a reply, what he said, or if he failed to say anything, may be proven as in the nature of an admission.

Physician May Testify as to Wounds on Shaved Head.—In the homicide case of the State of Missouri vs. Tettaton, where the evidence of the physicians disclosed the fact that it would have been impossible for the defendant to have been cut in the head as he was by any other person than himself, it was insisted that the court should not have permitted witnesses to testify with respect to the condition of the wounds on his head, as they existed after his head was shaved. The contention was that the act was involuntary, and was compelling the defendant to give evidence against himself. But this contention, the Supreme Court of Missouri, Division No. 2, says was not borne out by the record, which showed that it was not only voluntary on the part of the defendant, but that it was necessary in order to enable the physicians to treat the wounds. Yet, even if the shaving of his head had been against his will and consent, there can be no question, it holds, but that physicians could have examined his head, and then testified to the condition of the wounds, their character, and whether or not done with a sharp or blunt instrument.

Proper Evidence of Injury of Private Parts.—The Supreme Court of Wisconsin says, in the personal injury case of Guhl vs. Whitcomb, that it can not pass silently the reception in evidence of photographs showing rear views of the plaintiff's person, nude from below the shoulders to mid-thigh. Such photographic exposure of the body of a 20-year-old girl in a court room full of men is even more grossly improper and shocking, it goes on to say, than the conduct disclosed in Brown vs. Swineford, of which this court thus expressed its condemnation in the scathing words of Chief Justice Ryan: "No such indecency is ever necessary, or should be tolerated, in court. If the condition of any private part of the body of any party, male or female, is material on any trial, it should be privately examined by experts out of court, and expert testimony be given of it. Such an exposure as was made in this case, if made without leave of the court, might well be punished as a contempt. Made with the sanction of the court, it is none the less improper and indecent, well calculated to disgrace the administration of justice, and to bring it into ridicule, if not into contempt. It is hoped that this court may never have another occasion for such censure." To those words, the court now declares, it can not and need not add, save to reiterate the sentiments they express, and to invoke for them the careful attention of those, whether of court or bar, who may be tempted to repeat such defilement in a court of justice.

Opinion of Physician Called After Making of Will.—A physician visited, at about noon, or after it, a man who, there was evidence tending to show, had had a slight stroke of paralysis the night before, and had made a will between 10 and 11 o'clock in the forenoon. He did not get an intelligent word out of the man, although he considered that he had partial intelligence. Under these circumstances, and the physician having got the impression from the inquiries he made that the man had been in the same condition from early morning, the Supreme Court of Michigan holds, Lange vs. Wiegand, that it was clearly competent for the doctor to express an opinion as to the mental capacity of the man at the time he saw him. It adds that it did not conclusively appear that the condition of the man had changed so materially after the time of making the will that the opinion of the doctor as to his mental capacity at the time of his visit was wholly without force. On the other hand, it holds that it was error to charge the jury in this case that if the statements made by three witnesses named were true, they showed a mental capacity in the man to make a will, over against which "you put the statements of what the doctors say, and what they say about his not having awakened sufficiently to speak, and so forth." It says, in explanation of its holding that this was error that the doctor did not see the man until the afternoon. The will was made between 10 and 11 o'clock in the morning of the same day. He was failing rapidly from a stroke of paralysis. His condition, according to the testimony of several witnesses for the proponent of the will, was not alarming while the will was being signed. He lay propped up in bed, and, though his right arm and hand were considerably affected, they testified he could talk, and that he bore no evidences at that time of mental aberration. In the afternoon, however, his condition very much changed. Under these circumstances, what his condition was at that time, the court holds, could not be weighed against the testimony of wtinesses, who stood unimpeached, as to the condition when the will was made.

On Criminal Abortion and Dying Declarations.—The Court of Appeals of Maryland says, in Worthington vs. State, that, whatever may have been the severity of the earlier common law, the proposition is too broadly stated that death resulting from criminal abortion has always been murder at common law. The crime of abortion is a misdemeanor, only, at common law; and the Maryland statute, while broadening the scope of the common law, and increasing the punishment, still leaves the crime a misdemeanor. Thus, it has been said that "causing the mother's death in attempting an abortion is only manslaughter at common law, if the attempt is not made in a way that endangers the mother's life. In the latter case it is murder." It is only in jurisdictions where abortion is raised by statute to the grade of felony that causing the death of the mother is necessarily murder. It is common knowledge, the court goes on to say, that death is not now the usual, nor, indeed, the always probable, consequence of an abortion. The death of the mother, doubtless, more frequently resulted in the days of rude surgery, when the character and properties of powerful drugs were but little known, and the control over their application more limited. But, in these days of advanced surgery and marvelous medical science and skill, operations are performed and powerful drugs administered by skillful and careful men without danger to the life of the patient. Indeed, it is this comparative immunity from danger to the woman which has doubtless led to the great increase of the crime, to the establishment of a class of educated professional abortionists, and to the enactment of the severe statutes almost everywhere found to prevent and punish this offense. The woman takes her life in her hands when she submits to an abortion, be she wife or maid, but her death is no necessary element in the procuring of an abortion; and the application of the harsh rule that the death of a woman, resulting from a criminal abortion upon her, is murder would have no effect in the repression of that abhorrent crime, which can only be efficiently dealt with by severity in the enactment and administration of the law punishing the attempt upon the life of the unborn child. The corpus delicti of the offense of abortion is the destruction of the unborn infant. The crime is complete, with the death of the woman or without it. Her death is not a constituent element of the offense. But in this case the indictment was not for abortion. It was an indictment which charged manslaughter, and the facts of the abortion were simply alleged there as going to show what caused the death, just as if it had been alleged that the means of death were by shooting the woman with a pistol. Under such an indictment, dying declarations, the court holds, are receivable, although in a prosecution for abortion it would seem they would not be where the death of the woman is no part of the facts which go to constitute the crime. It is certain, it says, that dying declarations can only be received where the death of the deceased is the subject of the charge, and the circumstances of the death the subject of the declaration. It is essential that actual danger of death must exist, that there is full belief that it is actually impending, and that death ensues. Any expressed or clearly visible hope of recovery will render the declaration inadmissible. But the declarant's own belief at the time is the criterion of admissibility. It is not material that others, even the physician, thought differently and had hopes of recovery.

2. **Laboratory Feeding.**—Some of the questions in regard to infant feeding are noticed by Griffith, who insists on the value of milk laboratories as they now exist in large cities. One of the secrets of successful feeding is, he thinks, to have the infant begin with a low percentage. We should not take mother's milk as the standard for artificial feeding. The proteids of cow's milk differ from those of the human species, and this mistake is sometimes made. In the first two weeks of life the child should be treated with .5 per cent. proteid, and even later in the first year it is wise to begin with low proteid. We should begin with a small amount of fat, 2 per cent. instead of the normal 4 per cent. of woman's milk and a little less than the normal percentage of sugar, 6 per cent. instead of 7, for example. For a very young baby, therefore, who has had signs of indigestion without serious disease, the formula of 2 per cent. fats, 5 per cent. sugar, .5 per cent proteids is best. This will not answer long, but the method of increase will depend upon the conditions. It is important to weigh the child weekly or semiweekly. If the increase in weight does not progress satisfactorily, look out for unfavorable symptoms and alter the formula. In any cases where the percentage feeding does not seem to agree, we should be sure the error is not with our own formula or method. There are idiosyncrasies in special cases, but they are rare and not to be our guide to practice. He gives an account of three cases showing the need of adaptation to the conditions in percentage formula feeding.

3. **The Widal Test.**—Robin describes the technique of the Widal test, the special apparatus devised by him for the drawing of but one drop of blood, and insists on the need of high dilutions in making the test, since one drop of normal blood, diluted 1 to 5 or 10, may at times produce agglutination. It is not difficult to obtain from the bacteriologist a culture of typhoid bacilli which can be kept in sealed tubes and be available at any time. The last cultures he had were sealed for eight months, and the bacteria none the worse for the confinement. He points out the difference between pure and pseudo reactions, and gives illustrations of them. The time limit is a matter of much importance, and the irregularity practiced in this regard is to be deplored. He would recommend the following: Dilution 1 to 10, time limit five to fifteen minutes; 1 to 20, fifteen to thirty minutes; 1 to 40 to 1 to 100, thirty to sixty minutes; 1 to 100 to 1 to 200, one to two hours. That would mean that if within the specified time a considerable number of bacilli are found actively motile or, if dead, fail to arrange themselves in clumps, the reaction is to be pronounced negative, irrespective of the clumps which have already formed. He says there is no reason why the general practitioner who is removed from municipal laboratories may not make the Widal test himself, if he is properly instructed.

7. **Erythromelalgia.**—Elsner reviews the history of erythromelalgia and reports cases. He does not consider the condition as yet worthy to be called a disease per se; it seems to be attendant to a great variety of conditions. He is inclined to consider it as a circulatory rather than a nervous disorder, the result of secondary vascular changes.

9. **Gelatin Injections for Aneurysm.**—Three cases of thoracic aneurysm were treated by Conner by gelatin injections. In two they had to be discontinued because of severe local pain. In one case where seven injections were given, a very slight improvement could be detected, in another a slight increase of the symptoms was noticed, while the third died under treatment, from rupture of the aneurysm. The autopsy showed no evidence of recent thrombosis, though the conditions were favorable for such formations. Aside from pain and local irritation no bad symptoms were observed in any case here noticed. He is not ready to conclude that the method has no therapeutic value, since in none of these was the treatment fully carried out, but he thinks its usefulness is seriously impaired by the severe pain which it often produces.

10. **Ameba Coli.**—The following, Craig claims, have been demonstrated by the study of stained specimens of ameba coli: 1. That vacuolization is a degenerative process, as the young amebæ show no vacuoles, the full-grown healthy ones, few, while the amebæ in which they are most numerous are degenerate bodies, showing neither a nucleus nor inclusions of any kind. 2. That there occur in all but the degenerate forms of amebæ, small, round or oval, unstained areas, uniform in appearance, and most numerous in the large, full-grown forms, and entirely absent in the vacuolated shells of amebæ. These areas resemble similar ones observed in stained, segmenting malaria plasmodia, which are, in them, due to the young spores, which take the

stain but faintly. Reasoning from analogy, it may be that these areas in the amebæ are also spores. 3. That in the protoplasm of the ameba, there occur peculiar structures, evidently not bacterial in nature, the significance of which it is impossible to decide. It may be that they are certain crystals which occur in the feces and which have been absorbed by the amebæ. 4. That degeneration of the amebæ takes place in two ways, i. e., by vacuolization and by fragmentation.

11.—See abstract in The Journal, xxxv, p. 448.

15. **Biliary Calculi.**—Beck reports his success with skiagraphy of biliary calculi *in situ*, and gives the essentials for success. The first condition is a strongly built and powerful tube which will bear a fifteen-inch spark for about five minutes without becoming too hot; it should be of medium hardness so as to permit the permeation of soft tissues without the denser ones, and this can be best decided by its effects on the hand. If the bones of the wrist appear grayish-black, but well defined, while the softer tissues show but little, the tube is suitable. If the tube is too soft the bones will be intensely black. The tube should always be new, as later they show less contrast. The position of the patient is also important; he should lie on his abdomen with about three pillows underneath his clavicles, so as to bring the gall-bladder nearer to the photographic plate. Another point is that the rays should not penetrate the abdomen in the vertical position, but from the side, so that the thick an less transparent tissue of the liver is not traversed in its whole diameter. The direction of the rays at an angle of about 70 degrees to the slant is best. The bowels should be freely evacuated. He admits that the method needs further improvement, but he maintains that even a faint skiagraphic reproduction of biliary calculi proves their existence to the expert, though a negative result cannot insure their absence.

17. **Specific Treatment of Dysentery.**—The points made by Cruikshank are that dysentery is contagious and infectious, that the germ is introduced into the system through food and drink, that the disease is the same wherever it is found and only varies in its intensity. As to the majority of therapeutic agents, they are usually useless and, in many cases harmful, but the sulphate of magnesium properly administered in the acute form of this disorder acts as a specific.

21. **Gonorrhea.**—Woodruff treats gonorrhea by the use of hot normal salt solutions, the good effects of which were first noticed accidentally, but which he has followed up with good success. He usually gives an astringent injection to use two or three weeks after leaving the hospital. He suggests the possibility that gonorrhea is a self-limited disease, with periods between forty and sixty days. Chronic and severe cases would then occur in persons of abnormal lack of resistance, and in those of bad habits generally.

23. **Colitis.**—Bolton reports a case of severe colitis treated by the formation of a cecal colostomy with a valvular opening through which irrigation of the colon was carried on. From the first the diarrhea began to improve, and at the end of two weeks no ulceration of the mucous membrane could be seen, while at the end of the treatment the condition was *apparently* normal; the patient had gained 10 pounds. A pad was worn for twelve days, at the end of which time the fistula healed. A small ventral hernia has appeared at the site, but he thinks it can be easily controlled by operation. In the future he shall adopt the intermuscular incision of the abdominal wall.

28. **Intestinal Anastomosis.**—Cumston's article is a historical one, in which he calls attention to the fact that in the work on surgery, published in 1769 by Bertrandi, he gave an account of a case where the trachea of a calf had been dried and softened in hot alcohol, then covered with Peruvian balsam and used as a bobbin in intestinal anastomosis with success. This method of intestinal anastomosis even then was an old one, since it was mentioned by Pierre d'Argellata that four surgeons had employed it, the pieces of trachea being afterward expelled in the natural way. He is certain that this refers to the end of the thirteenth century. He also mentions other operations described by Bertrandi, including that for extrauterine pregnancy.

38. **Non-Obstructive, Post-Operative Anuria.**—Brown reports a case of post-operative anuria due to delayed surgical shock, which was interpreted as a manifestation of auto-intoxication due to renal suppression in a person of poor constitution and emotional temperament. The possibility of the septic state was also conjectured. He uses the case to point out the mistakes made and the measures to be taken for their avoidance in future similar cases. In such a patient with a questionable heart he would in future give a large stimulating enema and have it repeated immediately after the operation if there was then the smallest indication. Nitrous oxid gas and ether should be employed for the anesthesia, preferably to chloroform. The medication should be given subcutaneously or by rectum, and all vomiting met with hot lavage. The first manifestations of anuria would be looked upon, where the pulse is small and rather rapid, as due to vasomotor paresis or cardiac weakness with lowered renal pressure, the result of shock, and stimulation to be employed.

39. **Stone in the Kidney.**—Bevan's article notices the use of the *x*-ray in the diagnosis of kidney calculi: As regards his own experience, which includes seven nephrolithotomies and two cases in which the stones were removed from the kidneys converted into pus sacs, he has been agreeably surprised in having no mortality, and he believes that the mortality from nephrolithotomy is not so great as we have beeen led to suppose. The prognosis as regards permanent cure is not so good as after operation for bladder stone or gall-stone, still, in some cases the operation has been followed by complete and permanent cure. He thinks the best incision for nephrolithotomy is an oblique one, beginning a finger's breadth below the last rib and running obliquely downward and outward to a finger's breadth above the anterior superior spine. This can be easily extended by splitting the external oblique downward to get the fullest exposure of the ureter, if necessary. The kidney is freely loosened from its bed so that it remains attached only by its vessels and ureter, and can be brought out of the wound in perfect view unless in very obese patients, while the operator can in them control the pelvis and vessels. He says: "Don't be afraid of large incision." "Don't be afraid of dislocating the kidney." The kidney, its pelvis and vessels under perfect control, is split by an incision two or three inches in length on its convex border, the pelvis opened and examined, and the stone or stones removed. Then wash out with a hot normal salt solution, carefully examining for remaining fragments. If none are found close the wound with deep medium-sized catgut, the external wound with buried catgut and silkworm gut, excepting a small portion for drainage. Where pus infection exists, the pelvis should be drained. Where stone is found by the *x*-ray and can be diagnosed by palpation, a small incision can be made and the pelvis closed by Lembert's sutures, as has been done by Morris. Care should be taken to prevent pushing of small stones into the pelvis and dilated ureter and, where the kidney is not brought out of the wound, pressure can be made with the fingers to collapse the pelvis and prevent a stone slipping in during the efforts at removal.

40. **Hernia of the Fallopian Tube.**—Morf reports a case of this condition and discusses its etiology, morbid anatomy and treatment. In this case the woman probably had congenital hernia of the left oviduct, complicated by epiplocele, the fat of which underwent serous change. Shortly before the hernia became irreducible, the patient probably acquired an acute vaginitis, the infection extending upward into the hernial sac. The microbes, finding a favorable culture-medium on the omentum, multiplied, exudation and pus formed, and as a result the hernia became increased in size and irreducible. The diagnosis is not always possible in these cases; in none of those reported has it been absolutely correct. The radical operation, he thinks, is demanded in all instances. The paper closes with abstracts of reported cases in the literature.

42. **Resection of Pendulous Abdominal Wall.**—Peters reports a case of pendulous abdominal wall in which an immense transverse gore of the enlarged adipose abdomen was taken out, leaving the patient after recovery in a good condition with a reduction of over 60 pounds of weight and a normal abdomen. He

refers to a previous case similarly operated on by Bullitt with good results.

43. **Hydrocele.**—Tait recommends eversion of the tunica vaginalis as a cure for this condition, and describes the operation; also a simpler one first published by Longuet and given his name, though Tait himself employed it independently of Longuet's publication. The operation consists essentially in the inversion of the cellulo-fibro-vaginal layers without decortication or hemostasis; the testicle is transposed. A transverse fold is taken up over the testes and cut with the scissors down to the serosa, under local anesthesia. The serosa is cut in like manner, neither cut exceeding 3.5 cm. The testicle is then drawn out upward and forward, the scrotum being at the same time pulled in the opposite direction. The tunica vaginalis and overlying fibrocellular tissues follow and are turned inside out. One or two sutures are taken to secure the vaginalis in its new position; these stitches are placed in such a manner as to avoid injury or strangulation of the cord. Chromic catgut (two weeks) is perhaps preferable to the ordinary gut, which is absorbed too early. The testis is not placed in its original position, but a new bed is made for it in the middle of the inner lip of the incision by gently dissecting the cellular tissue with the finger. The resulting new cavity is inside of and parallel to the old cavity. The testicle is slightly twisted on its axis, not being in normal anteversion but in retroversion, rotated inward a quarter of a circle and lying directly against the raphe. The position of the testicle may be defined as retro-latero version. The wound is then closed with two or three stitches. The operation is completed within a minute or two; no hemorrhage is noted; and the immediate effects are barely noticeable, thereby differing radically from all the other methods. There is no local reaction or infiltration of the soft parts, no tenderness, and within a few hours after the operation palpation of the testis does not elicit more than the normal sensitiveness. Consequently, the patient may resume his work on the following day. Nothing simpler, neater, nor more expeditious could be imagined. In a very large hydrocele, Longuet combines the above procedure with partial excision of the vaginalis, using elastic clamps and a continuous hemostatic catgut suture on the cut edges of the serosa. He claims that this operation will prove serviceable in the majority of cases of hydrocele and cysts, also where the surgeon is desious of exploring the serous sac of the tunica vaginalis, testis, or epididymis, and in some cases of hernia complicated with hydrocele and in the presence of numerous cysts. Three cases are reported.

50. **Hallucinations.**—The general subject of hallucinations is reviewed by McCorn, who summarizes his conclusions in regard to them as follows: Hallucinations are not new creations; they are composed either of present or of latent memory-pictures or ideas, and are accordingly designated concomitant or spontaneous, respectively. They are not due to an external stimulus, but to one within the sense organ itself—one acting on its sensory tract or the sensation cells of the brain cortex. Hallucinations may affect any or several of the senses simultaneously, and influence thought and action according to their contents and the importance ascribed to them by the patient. They may be due to toxic conditions—whether caused by drugs or infectious diseases, disorders of nutrition, the effects of extreme heat or cold—and often accompany the functional neuroses. They are particularly common in paranoia and dementia in their various forms, but occur more rarely in the affective psychoses.

55.—This article has appeared elsewhere. See The Journal of February 2, ¶116, p. 350.

56. **Bacterial Poisoning in the Lower Organisms.**—Klingmann's paper is a statement of the facts which have already been published by him and noticed editorially in The Journal, xxxv, p. 1218, on the influence of bacterial toxins on vegetable forms of life, algæ, etc.

60. **Interstitial Keratitis.**—It is assumed by Callan that the majority of cases of this condition are due to inherited syphilis, and the question may arise as to whether this can be avoided. The conclusions which he reaches are: "The offspring of syphilitics show the evidences of the inherited taint in only a slight percentage of the cases; that is, if we except those children under 5 years of age. Only a slight percentage of such children develop interstitial keratitis. When the disease attacks one eye, all our treatment appears to be powerless to prevent its development in the fellow eye. We may possibly delay, but we can not prevent, the outbreak of interstitial keratitis in certain cases."

72. **Trachoma.**—The method proposed by Jameson seems to be a sort of mild superficial grattage, with a special instrument devised to attack superficially and repeatedly and thus eliminate all granular growths.

76. **Influenza and Glaucoma.**—The physiologic relationship of influenza and glaucoma are illustrated, de Schweinitz thinks, by the case which he reports. It started, he says, through the axial neuritis which is so frequently caused by epidemic influenza and which more frequently than perhaps any other condition, is a starting point of glaucomatous excavation of the nerve-head.

77. **Methyl Alcohol Blindness.**—Cases of Jamaica ginger blindness that have been reported have been already noticed editorially. Harlan reports two in which an analysis of the ginger essence was made. It seems that blindness is not only caused by Jamaica ginger essence, but by others, as lemon, peppermint, etc., which are made up with methyl alcohol.

79. **Jaundice from Gastroptosis.**—The patient whose case is reported by Steele had an attack of abdominal trouble, possibly hepatic colic or some gastro-intestinal inflammation which probably involved the peritoneum, with formation of adhesions. After this came symptoms of chronic gastro-enteritis. In the course of a year jaundice appeared, and steadily increased, with moderate loss of weight, and slight secondary anemia and leukocytosis. Inflation of the stomach showed decided gastroptosis. The stomach was restored to its place by a belt and the jaundice immediately began to improve and in seven months disappeared. Bile is not present in the urine and has reappeared in the stools. He discusses the possibility of gastroptosis causing jaundice by obstruction of the bile-ducts, and concludes that this can not be the case without adhesions from some previous inflammatory condition, such as was supposed to have occurred in this case.

81. **Ammonium Persulphate.**—Ravenel and Gilliland have experimented with this salt, which has only of late years been reduced to such a price as to make it available for a disinfectant. He finds that, experimenting with solutions of various strengths, it kills the microbes of diphtheria, typhoid, and ordinary pus microbes at various periods from fifteen or twenty minutes to one and one-half or two hours, and the anthrax spores are killed by a 5 per cent. in thirteen hours. He finds it also of considerable value as a deodorant. Forty c.c. of a 5 per cent. solution was added to 530 c.c. of decomposed blood and boullion, and almost thoroughly deodorized in twenty minutes. Ribbons of delicate colors, immersed in a 10 per cent. solution for one and two hours, showed no apparent change of tint.

83.—See abstract in The Journal, xxxv, p. 1171.

86.—Ibid., p. 1104.

88. **Gall-Bladder Surgery.**—Three cases are reported by Munro, which he thinks point out the necessity of early operation in all marked cases of gall-stones, since, after the attacks are allowed to go on, the operation becomes, for some reason not yet explained, a serious undertaking. The ideal cholecystotomy is worth trying if the surgeon is sure that this is not contra-indicated. Cholecystitis is better drained surgically than medically, other things being equal. The possibility, not so remote as has been heretofore considered, of pancreatitis, should weigh on the side of urging operation for gall-stones. The majority of gall-bladders can be reached easily and properly through a short vertical incision in the outer third of the rectus. Any nerves coming in the way can be pushed aside and not destroyed if care is taken.

90.—See abstract in The Journal of January 12, p. 127.

91. **Hernia.**—Kocher's new operation is described by Renz, which is a modification of his old method, as follows: In the new operation the small opening above and outward to the

internal ring is continued into the peritoneal cavity, a long forceps introduced into the inside of the sac, its end caught and pulled; the other steps of the operation are the same as above. This inversion of the sac is the essential point; it forms a pyramid toward the inside of the abdominal cavity instead of outward into the canal; consequently, every time the patient coughs, the abdominal wall distends and he is, as it were, trying to pull his internal ring into the abdominal cavity, or at any rate the sac. With this operation the patient remains in bed but two weeks; the results are excellent, Kocher claiming but 3 per cent. of returns; the operation is simple and is ideal in its plan. Unfortunately the method is not applicable to direct herniæ, nor in the oblique ones where the sac is too thickened and enlarged, but in suitable cases Renz finds it highly useful and recommends it.

99. **Sphenoidal Wing Sinuses.**—Douglass calls attention to the extension of sinuses of the sphenoid into the sphenoidal wings, and the variation of their development, illustrating the anatomical possibilities with a number of plates. The practical bearing of the existence of these cavities is that disease may continue in them even after that in the ethmoid cells is cured. These accessory sinuses, therefore, will escape treatment and trouble may ensue The possibility of their existence should be borne in mind and their anatomical relations studied.

100. **The Tuning-Fork Test in Antral Disease.**—The use of the tuning-fork for testing for disease of the maxillary antrum is recommended by Kuyk. If the antra are free and clear, the tone may be heard with equal distinctness and for a like duration over each side and on the first and second molars, but if one antrum contains fluid, its tone should be fainter. If the symptoms are obscure and transillumination gives a shadow on the one side and none on the other, with subjective symptoms indicating disease, the use of the tuning-fork may confirm the diagnosis. He has also used it in cases of frontal sinus disease, and thinks it may be used with other conditions, in mastoid and ethmoid infections.

104. **Choroidal Melanosarcoma.**—This article reviews the symptoms and stages of the condition and reports three cases. Alter's conclusions are summarized as follows: "1. Melanosarcoma of the choroid is a fatal disease. Probably not more than 15 per cent. make an absolute recovery after operation. 2. The prognosis of this affection, though grave in all stages, is best with an early operation. 3. It is well-nigh impossible to make a diagnosis of acute inflammatory glaucoma due to tumor when the fellow-eye presents a glaucomatous aspect, as evidenced by Case No. 1 recorded in this paper. 4. The round-celled highly vascular tumor speaks almost unequivocally of a fatal termination. The spindled celled growth gives a much more hopeful outlook. 5. The presence of melanin in the urine give strong evidence of metastasic involvement. It foreshadows a fatal termination."

117. **Climate of Western Texas.**—Rawlings describes the climate of El Paso, which he thinks possesses the essentials of sunshine, dryness and rarefied air suitable for the proper treatment of pulmonary diorders. Bronchial asthma is also greatly benefited, but the fibroid form of phthisis is not so much so, nor is laryngeal tuberculosis. The climate is at its best for these cases for seven months of the year. The mid-summer months, which is the rainy season, are less advantageous, but there is a region, high and spruce-covered, within 120 miles, which furnishes ideal conditions. Cases in the late stages are not benefited by the climate anywhere.

138. **Suprarenal Extract.**—Bates gives his experience with suprarenal extract in various ocular troubles. He has treated many recent cases of conjunctivitis successfully with local applications, and found it a valuable remedy in keratitis, iritis, glaucoma and lacrimal disorders. Two cases of lacrimal fistula have been cured without other operation. As a hemostatic for eye operations, he believes it the best, and he considers it a safe remedy to use in all inflammations of the eye. When it does good after the local use, the benefit is apparent in less than a minute.

147. **Hemoglobinuria.**—McElroy endorses as rational the advice of Bastianelli to use quinin when malarial parasites are present in the urine, and not if they are absent. If quinin has been given before hemoglobinuria appears, and no parasites are in the blood, it should be suspended, but if the parasites persist, it should be continued. He reports cases and thinks on the whole, however, that the better plan is to give quinin to prevent the attack, and suspend its use as long as hemoglobinuria and albumin continue. Then, if fever continues, quinin may be given successfully without danger of producing another attack. In oliguria and anuria the best plan is to withhold quinin. When diarrhea is absent, he gives calomel in 10-gr. doses, at intervals of three hours for three doses, and if this does not act sufficiently, assists its action with hyposulphite of soda. At the first appearance of oliguria the safest procedure is to apply dry cups to the loins, followed with poultices, and administer normal salt solution hypodermically.

148. **Hemoglobinuria.**—Laws thinks it is necessary to determine whether the micro-organism is active, to intelligently treat a case of malarial hemoglobinuria. Where the organism is still active, he would give quinin, but where the condition is more of a toxemia due to spent activity of the organism, we should discard it. As a general rule, where the fever is of an intermittent type, or even a remittent type with chills, quinin should be given, but remittent fever with slight variation in the temperature is not often thus benefited. He mentions the use of sodium hyposulphite, but does not apparently endorse it. He thinks, however, elimination through the bowels and kidneys is of prime importance.

152.—See abstract in The Journal, xxxv, p. 841.

British Medical Journal, March 9.

Neglect of the Actual Cautery in Surgery and Its Value in the Treatment of Pruritus Ani. William M. Banks.—The neglect of some old methods which in former times had been abused is regretted by Banks, and he calls special attention to the use of the actual cautery which, he maintains, may be of great value in certain conditions. Among them he mentions syphilitic periostitis, in which the cautery might be more extensively used, especially in the late forms. He reports a typical case in which he obtained relief with this method where other means had failed, and also certain joint diseases, not the white swellings of children, but the gouty or rheumatic gouty conditions. He says that we have neglected this method too much and gives two or three patients' accounts of their experience with it after others had failed, one in which chronic arthritis of the knee, for example, had been treated with the Thomas splint without benefit and was almost immediately helped by cauterization. Still another condition is spinal inflammation after injury, and in conclusion he mentions a disorder for which the use of this remedy seems to be almost new, viz., pruritus ani. The great majority of the ordinary cases of this form of pruritus are curable when the cause is found out, but there are a certain number in which he could find no evidence of any local or systemic cause, and yet the itching is most intense. For some of these cases he believes the actual cautery will be the best form of treatment and reports one or two. It is only in those very serious cases in which no cause can be found that he ventures to recommend it; he has used it perhaps a dozen times for this purpose in the last twenty years. The value of the remedy, he says, lies in its being unfailingly curative in certain otherwise intractable cases.

Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. J. Mitchell Bruce.—This is the first of a series of Lettsomian lectures on diseases and disorders of the heart and arteries in middle and advanced life. The mode of inquiry which Bruce purposes to follow is by an analysis and study of a large number of instances, their origin, clinical characters, course and result. He thinks that perhaps our attention lately has been too much confined to the pathologic states of the heart and arteries and too little to causes which produce them. Arterial sclerosis is too often accepted as the final diagnosis, without regard to the actual nature of the general pathologic factors, whether strain, syphilitic, gouty, or otherwise. He first notices the normal heart after the age of 40. The blood-pressure up to 45 is apt to be high, but at that age remarkable changes occur. While the arteries continue to increase in circumference, the blood-pressure falls and the heart begins to diminish in size. These three features characterize the circulation for the next twenty years. The fall in the size of the heart is partly accounted for by the widening of the arterial trunks, but not entirely, and the other causes which he suggests are the probable reduction of mechanical stress due to bodily relaxation, the loss of vasomotor tone in the splanchnic area, and chronic diseases which come on at these periods. At 65, other changes occur: the peripheral resistance becomes increased, the blood-pressure rises, the heart once more increases in size, till, at 75 years, it is as large as at 45, and the hemoglobin value of the blood again proves to be higher. The arteries continue to grow wider, thicker and longer, another proof that the size of the heart is not diminished altogether by their caliber. These become strengthened by the fibroid tissue and the heart responds to the altered mechanical condition in the arteries. In the great majority of cases of persons who have passed to old age, the arteries are still generally sound, according to the investigations of Humphry and others, and the actual changes may be considered probably not normally senile in their nature. They are rather the effects of pathologic processes which the author enumerates. 1. First among these he mentions physical strain. He says that we must speak with due caution as regards muscular exercise, but he feels sure that after 45 years of age, excess in this direction may be dangerous. The principal safeguards which the arteries possess against strain is their extensibility and elasticity, but the disorders liable to occur at this age, including gout, are just the ones which are accountable for weakening of the walls of the vessels. 2. As to the nervous system, he mentions cases where nervous strain in conditions of special stress have caused arterial and cardiac degeneration. However clear the direct connection between nervous strain and cardiac vascular disease happens to be in some heart cases, it is in others unreal and this is a matter of great importance. The nervous temperament often drives the subject of it to physical overwork with insufficient rest or sleep, and to the unwise attempt to remove the nervous exhaustion by violent muscular exercise. Worry often induces recourse to alcohol and stimulants, while many of the complaints of nervous depression, lowness and worry are really due to gout, influenza, etc., which are at the same time the true cause of the cardiac symptoms. 3. Extrinsic poisons, alcohol, tobacco, tea, coffee and lead are next considered. There is no need of proof of the reality of the connection of these with cardiac disorder, and they will be mentioned further on under the head of diagnosis. 4. Disturbances of metabolism are taken up next, including gout, which seems to be favored by substitution of quiet for active healthy exercise, and while the demands on the growth of the alimentary system have declined, the pleasures of the table are too much indulged in, with the result of functional disorders of the liver and gout in various forms and many other disorders of that character. At the same time the arterial tension rises and stimulation of the vasomotor center by nitrogenous waste occurs, and the arterial pressure, heart-vessels and kidneys are kept under excessive strain to carry off the extrinsic poisons; like other vessels working under strain, they are the first to suffer, so we have chronic Bright's disease, cardiovascular degeneration, etc. 5. Syphilis by no means always ceases to attack the organs of circulation after 40, and is a standing danger to the heart and arteries of men of middle age, and even in declining years. 6. Among acute diseases he notes influenza in particular, but also typhoid, rheumatism, diphtheria and syphilis in various forms. 7. The chronic disorders, anemia, exhaustion, etc., are next considered. 8. Among complex causes he first mentions emphysema and other chronic diseases of the lungs and pleura, which strain the right ventricle, and chronic Bright's disease, which similarly strains the left ventricle. Various agencies combine together and the result is disastrous. The wear and tear of life may be stated, in a general way, to be the cause of cardiovascular disease, but it must be remembered that in many cases the heart and blood-vessels may have been damaged in early life so that they fall victims to influences which would have been insufficient otherwise, and in the second place the heart and the vessels at 40, though apparently free from danger may be molecularly weak and unable to offer effective resistance even to ordinary strain. Lastly, the author calls attention to family idiosyncrasy, as in the case of hereditary senility where the patient becomes prematurely old. A type of cases described as family heart is noticed, where cardiac disease seems to run through various members of the family. We find men, say 30 years of age, with vessels already enlarged and lungs emphysematous without any history of respiratory strain.

Histology of the Urinary Tract in Its Relationship to Morbid Urinary Deposits. G. LESLIE EASTES.—The author first notices the normal and morbid histology of the urinary tract, describing the epithelial linings in the different parts. The Malpighian capsule and its neck are lined with a flattened epithelium very similar to that of the serous cavities. The first convoluted tubule has individual rodded cells with granular-looking protoplasm toward the free edge. The descending loop of the tubule and loop of Henle are lined with clear flattened cells, while the ascending limb and second convoluted tubule are like the first portion of the tubule with granular rodded epithelium. The junctional tubes and ducts of Bellini, which latter open directly into the pelvis of the kidney, have an epithelium consisting of clear cubical or columnar cells. In the course of over 6000 microscopic examinations of urine, from cases of nephritis where centrifugalization was practiced, he has never been convinced that he has seen the clear flattened epithelial cells of the Malpighian corpuscles. He has, however, he believes, recognized the granular rodded epithelium, and the cubical or columnar epithelium of the latter parts of the tubules is most commonly found when renal epithelium is present. This is what might be expected since the lumen of the collecting tubules is broad enough to allow the passage of isolated cells with ease, while the lumens of the loop of Henle and of the collecting tubules are so small that it is a matter for surprise that the epithelium, peculiar to those situations, when shed, can squeeze its way through. In a few cases of examination of the urine in carcinoma of the kidney he has found abundance of renal epithelium. Epithelial cells do not appear isolated as in tubal nephritis, but were frequently found in clumps indicating a rapid proliferation. Of sarcoma of the kidney, cysts, angeioma, etc., he has nothing to say. In a few cases he found indications which led him to suggest the existence of buried calculus, which was found later. These indications were the characteristic renal blood, with hyaline casts, epithelial cells, the size, shape and appearance of which suggested an origin in the collecting tubules; there were no epithelial casts, but blood-casts were present. In every case there was much free uric acid in the deposit, and the crystals aggregated together. Pelvic epithelium was lacking, or, if present, in very small quantities. Chemical examination showed more albumin than was accounted for by the blood present. There was also in each case a history of tender kidney with, usually, reflected pain. The characteristic epithelium of the renal pelvis is what is known as transitional. It consists of about four layers; the free edge with flattened cells; the next one or two, spindle or pear shaped, and the last layer composed of cells which are remarkably pleomorphic. The cells of the deeper layers are most easily recognized and the commonest forms a rounded body with granular contents and nucleus, usually tailing off into prolongations, the length of which may be two or three times that of the diameter of the body. These are only shed when there is extensive damage to the renal pelvis and the movement of the stone frees them. There are also usually blood and hyaline casts, and a slight though constant leucocytosis in this condition. In pyelitis due to other causes, similar cells, together with pus, are usually found, and the deposit contains casts. When the pyelitis is due to any other disease than tuberculosis, numerous bacteria are present. Eastes frequently noticed that in pyelitis casts are present which are broad and contain many bacteria, though pus casts are rare. In all lesions of the renal pelvis he has found more albumin than the microscopic examination would apparently indicate. The renal pelvis may contain neoplasms usually of the papillomatous variety, and they not infrequently become malignant. He has been able to diagnose this condition from an examination of the deposits. Of the ureter, he has nothing special to say, but the diseases of the bladder that can not be diagnosed by examination of the deposits are very few. In cystitis the cells are usually derived from the surface of the epithelium, and there are few of the more characteristic tailed and pear-shaped cells of the deeper layers of the mucosa. In the epithelium the cells are highly pleomorphic, but the most characteristic cells are found in cases of villous growth; papillomata usually, but sooner or later almost certainly become malignant, with a marked tendency to infiltration at the base. These cells are exceedingly long and of remarkable thinness. The urethra is lined with a columnar epithelium, but it is rare to see this in perfection in the urinary deposits. It is only seen well where a small calculus has been passed. In gonorrhea or urethritis of septic origin there is much epithelium, but it is swollen and altered in appearance. If the prostate supplies *fresh epithelium*, it is unrecognizable. The only thing he has to say about it is that in the urine of lads between the ages of 14 and 20, which is at the period of prostatic growth, he has frequently found clumps of clear, luminous, pear-shaped cells imbedded in a mucoid material. He has never seen this in girls, and therefore is inclined to think they may be derived from the prostate.

The Lancet, March 9.

Public Health and Housing. John F. J. Sykes.—This second lecture is devoted to the effects of certain kinds of dwellings upon the health. The author notices the peculiar conditions, bad ventilation, coldness, water-supply, etc., and remarks that these are the characteristics of the jerry-built dwelling-houses, the flimsiness being the cause. It has been shown by experiments that putrid gases predispose animals to the *infection* of attenuated morbid germs of disease, therefore, bad drainage and sewage will have its direct influence upon the health. The latter part of the lecture dwells on special forms of structures, windows, streets, admission of light, air, etc. He condemns the inside staircases for compound dwellings, as they are seldom properly ventilated. The common stairway should be the external one. He finds that it is a mistake to make large rooms for poor people, as it only leads to overcrowding. If the same sized family that could *live in one very large room* should live in two smaller ones, *there would be a better* sanitary condition, as well as physical well-being.

The Statistics of Gastric Ulcer, with Special Reference to Gastric Hemorrhage, Its Frequency and Fatality. Byrom Bramwell.—The accepted statistics of gastric ulcer are questioned by Bramwell, who thinks that the methods of estimating them are unreliable. It is probable that a larger portion than 5 per cent. have at one time or other in their life suffered from gastric ulcer. This may or may not be correct, and is only taken as approximately so. It is difficult to estimate the mortality from this cause, and he thinks it may vary very materially from year to year. He also criticizes Mayo Robson's conclusion with regard to the frequency of fatal hemorrhage. Errors of registration are *perhaps* less likely to occur in cases of hemorrhage than in cases of perforation. He believes that physicians of large experience will agree with him that death from hemorrhage *from gastric ulcer very rarely* occurs. He can himself recall but one case in hospital practice, and another that he saw in *consultation*, from what was *thought* to be duodenal ulcer, which, however, may have been gastric.

Pure Urea in the Treatment of Tuberculosis. *Henry Harper.*—The writer says he has used pure urea in a large number of cases of tuberculosis, and believes it to be a remedy of superior value to any used at the *present time*. With its administration, he applies treatment in the broad *sense, pure* air, plenty of nutritious foods, especially those rich *in albumin. These* act as an antitoxin, and render the tissues and fluids of the body proof against the bacteria finding a suitable *soil*. Twenty-nine cases are reported, all diagnosed microscopically as well as otherwise, and all apparently hopelessly bad cases, with recovery or *improvement*. He *remarks* that careful and systematic examination of the urea *excreted* by the kidneys previous to the treatment is needed. In only two cases in which he examined the urine with Martindale's ureameter has he found any increase in the quantity of urea excreted. *One* thing he feels sure of is that urea, *given* as he employs it, in scruple doses three or four times daily, or hypodermically, has produced cures in some and improvement in other serious or bad cases, that he has been *heretofore* led to conclude were incurable.

Janus (Amsterdam), February.

History of Syphilis. L. Hirschberg.—This thesis states that no ancient writer has described syphilis. Errors of interpretation have *been found in all* the passages that have been cited as purporting to describe what is *now known* as syphilis. A complete *description* is, however, on record in the Japanese government annals, dating from A. D. 900, when an official report was made of all the diseases existing in Japan at that time. The geographical discoveries of the fifteenth century permitted the introduction of syphilis into Europe with the malignancy usual to a newly-introduced disease. Certain parts of Europe were spared until long afterward, as *for* instance, Schleswig-Holstein and certain points of Norway, where the endemic raged comparatively recently with *pristine* malignancy. The Russian province of Kosloff is *now undergoing* this experience. After a disease has been common for *generations*, the receptivity of individuals becomes less. Besides this acquired immunity, there is also an ethnic immunity. In Iceland, *for* instance, although syphilis has frequently been imported, *it* rapidly dies out. The natives of Madagascar are likewise refractory to a certain extent, while severe cases are numerous among the Malays. "Government regulation of prostitution has a tendency to retard the creation of immunity and favors the evolution of severe individual cases."

Bulletin de l'Academie de Med. (Paris), February 19 *and* 26.

Hemoglobinuria in Malaria. Troussaint.—The hemoglobinuric bilious fever of tropical countries is the direct result of malarial infection. The *syndrome is caused by a process of* special, transient demineralization of the blood, the result of the *alterations* in the liver, due to the malaria. Treatment should comprise the *administration of small doses of quinin* and the mineralization of the blood plasma by *subcutaneous* or intravenous *injection of salt solution*. These *injections* arrest the destruction of corpuscles by stimulating urinary *depuration* and thus *favoring* the elimination of urea, bile *and sugar*, all of which are *demineralizing agents*. At the same time the *injections increase* the isotonic *power of* the serum.

Appendicitis á New Disease. Lucas-Championnière.—*Even if we group all the obscure inflammations* of the bowels in the past, which may *include cases of appendicitis*, the total *does not equal* the number of cases of appendicitis in our day. It is *evident, therefore*, that it is comparatively a new disease, *unknown to our fathers*. Lucas-Championnière adds that whereas he had *occasion* to observe 34 cases of abscess in the iliac fossa, between 1882 and 1899, since 1899 he has seen 19. He *suggests* that the increasing *consumption* of meat, the epidemics of la *grippe and* the *neglect* of the *old-fashioned* salutary *measure* of an occasional purge are the *factors* that have resulted in appendicitis. Robin stated in the *discussion which* followed, that he had noted appendicitis 82 *times in* 1585 cases of hypersthenic dyspepsia with hyperchlorhydria. In this condition the waste of nitrogen *averages* 12.61 per cent. instead *of* the *normal* 5.4 per cent., and this favors irritation *of* the intestines. Pinard called attention to the frequency *of puerperal appendicitis*, having had occasion recently to observe 3 *fatal* cases in *one month*. Kelsch maintained that appendicitis is the localization of a general infection. It is usually a *chronic* process, with acute recrudescences, at the instigation of *some* secondary factor. He believes *that* appendicitis is even *more common* than we yet suppose, but persists in a latent symptomless form. Sahli calls it an "angina of the appendix," and compares it to the *guttural exanthem of* scarlet fever, *pointing* out the follicular structure of the appendix.

Bulletin Gen. de Therap. (*Paris*), February 15.

Efficacy of Guaiacol in Varices and Serous Effusions. Allahverdiantz.—The *region of the* varices or of the effusion is painted with *guaiacol*, *covered* with oiled silk and cotton.

This treatment is repeated morning and evening for ten to twenty days. The author states that he has thus cured 7 cases of varices of three to seventeen years standing, rebellious to all other measures. 3 of varicocele, 5 of hemorrhoids and 2 of hydrocele, the latter being completely cured in three to five days, without surgical intervention. Pleuritic effusions and edema of all kinds do not require puncture but heal under the use of guaiacol.

Echo Med. du Nord (Lille), February 24.

Treatment of Hemorrhoids. H. Folet.—The surgical treatment should always be dilation, either alone or accompanied by excision. The latter is done with the bistoury in case of non-infected hemorrhoids, but the thermocautery is to be preferred if they are infected. In simple cases hygienic measures suffice, re-enforced possibly by hamamelis or argyrin, which are sometimes, Folet adds, of a "great psychic efficacy."

Systematic Operation in Traumatisms of the Urethra. Carlier.—Every person with an urethrorrhagia consecutive to a trauma of the perineal region should be operated on at once, even in the absence of a tumor or of ecchymosis, especially if he can not urinate spontaneously within fifteen minutes. Carlier combines external urethrotomy and urethrorrhaphy at one sitting. He has observed a number of instances in which anatomic lesions were very severe, although the symptoms indicated only a slight injury. The fact of urination after fifteen minutes does not speak for the absence of rupture, as the bladder may spontaneously evacuate its contents.

Gazette Med. Belge (Liege), February 21.

Treatment of Whooping-cough.—J. E. Godeau has asked a large number of physicians how they treat whooping-cough. He learned that 32 per cent. use belladonna; 23 per cent. carbolic acid; 20 per cent. the bromids; 12 per cent. creosote; 6 per cent. antipyrin and 2 per cent. opium. Godeau himself recommends inhalation of creosote and antispasmodics after the bronchitis is quieted, Belladonna, however, may be used before this.

Journal de Med. de Bordeaux, January 6.

Fate of Insoluble Substances After Subcutaneous Injection. X. Arnozan.—It has been supposed until recently that only soluble medicines were suitable for subcutaneous injection. Late researches, however, have established the mysterious fact that the leucocytes take up undissolved foreign particles and then have a tendency to congregate at the site of a lesion or any *locus minoris resistentiæ* thus bringing the medicinal substance exactly where it is most needed. Besredka administered a fatal dose of arsenious acid to animals after he had caused a cold abscess by inoculation with dead tubercle bacilli. A remarkable proportion of the total amount of arsenic was found in the pus corpuscles of the abscess. Others have also demonstrated that leucocytes loaded with foreign substances accumulate at the points where lesions exist, Landerer experimenting with balsam of Peru and cinnamic acid, Stassano with mercury and Montel with calomel and iodoform. The research of the latter is described in his thesis (Bordeaux, 1901). When a substance is dissolved in the blood plasm it becomes generally diffused throughout the organs, but when it is insoluble it is taken up by the leucocytes and carried to the blood-forming organs especially, and to the excretory glands. These facts suggest a possible explanation of the benefits of revulsive measures, of Fochier's fixation-abscesses, etc. The leucocytes loaded with the foreign bodies accumulate at the site of the lesion, and in case of foreign or autopoisonous substances isolate and thus tend to render them harmless.

Journal des Praticiens (Paris), February 23.

Toxic Dyspepsia in Children. Sevestre.—Children between 7 and 15 sometimes present symptoms which suggest a serious condition, but they are in reality merely manifestations of a toxic dyspepsia and yield rapidly to appropriate treatment, Headache is the principal symptom, aroused or increased by study, also insomnia or nightmares, and fever recurring at intervals of four to six weeks, with sometimes vomiting, persisting several hours to two days. The apex of the heart may be displaced outward by the dilated stomach, with arrhythmia and palpitation on the slightest effort. Appropriate diet, massage of the abdomen and cold morning douches or frictions will relieve the toxic dyspepsia underlying these symptoms. The gastro-intestinal atony can be counteracted by ten or fifteen drops before each meal, of a mixture of 3 gm. of tincture of nux vomica, 4 gm. of tincture of calumba and 5 gm. of tincture of illicium. Roast or broiled meats should be replaced by meat that has been sterilized by long cooking.

Combination of Autotoxic Dyspnea and Angina Pectoris. H. Huchard.—The patient whose case is described presented evidences of a toxic alimentary dyspnea from cardiorenal sclerosis, associated with true coronary angina pectoris and neuralgic or false angina from peri-aortitis. Each complication requires different treatment; the dyspnea is controlled by an exclusive milk diet for ten to fifteen days, with 50 cg. of theobromin two or three times a day. The milk diet is resumed for five or six days twice a month afterward, accompanied by 25 to 50 cg. of sodium iodid during the day. At other times the diet should be restricted to vegetables, fruits, a little meat, one powder of 50 cg. of theobromin once or twice a day and a glass of Evain-Cachat water. If the milk produces diarrhea, it should be controlled with bismuth subnitrate, 1 gm. to each cup of milk. Kefir is another effective measure for control of the diarrhea. Constipation will yield to one or two teaspoonfuls of magnesia, or the usual measures. The peri-aortitic false angina pectoris indicates revulsive or analgesic remedies, but the coronary, true angina requires vasodilating medication to reduce the blood pressure, inhalation of amyl nitrite, subcutaneous injection of trinitrin during the attacks, and, during the intervals, trinitrin, tetranitrol or iodids by the mouth. This reduces the pain of the angina but does not affect the dyspnea, which can be controlled only by promoting renal elimination by the milk diet, which must be kept up as directed, at intervals, for months or even years.

To Expel the Oxyuris in Children. Deguy.—Four days are required for the course of treatment recommended. First a calomel purge and milk exclusively, for twenty-four hours, then 5 cg. of santonin before breakfast for two days, followed by a rectal injection of a .5 per cent. solution of nitrate of silver after a cleansing injection. It is retained for five minutes and followed by an injection of salt solution to neutralize any excess of the nitrate of silver.

Revue Gen. d'Ophthalmologie (Paris), February.

Traumatic Atrophy of the Optic Nerve. A. Péchen.—Injury from penetration of a foreign body into the orbit may cause blindness at once, from lesion of the optic nerve, without any immediate ophthalmoscopic injury. In a personal case related, a boy of 14 hit his eye against an iron rod, in the dark. The next day he could not see with it but no lesion, external nor internal, could be discovered for nearly fifteen days, when atrophy of the papilla became evident. Péchin has been able to collect only twelve similar cases in the literature, the earliest dating from 1873. He remarks that the prognosis should be extremely cautious in case of the penetration of a foreign body into the inner or outer angle of the eye, even when it does not remain in the eye, and in the absence of any appreciable lesion. Complete amaurosis, under such circumstances, should suggest a grave lesion of the optic nerve. It may show first as a discoloration and later as progressive optic atrophy, which will soon differentiate it from hysteria or simulation. The mechanism differs from that of optic atrophy consecutive to fracture of the optic foramen, which is itself consecutive to a fracture of the base of the skull or of the arch of the orbit. The atrophy in this case is due to the stretching of the nerve, which may be complicated by a direct traumatism.

Semaine Medicale (Paris), February 27 and March 6.

Quinin Treatment of Malignant Neoplasms.—Launois has recently reported a case of inoperable mammary carcinoma in which he relieved all the symptoms and restored the patient to active life, with partial retrogression of the neoplasm, by subcutaneous injections of quinin, as recommended by Jaboulay

The latter has recently discovered that ingestion of quinin by the mouth is equally as effective in such cases as its subcutaneous administration. He gives one gram a day, substituting Fowler's solution two days in each week, and applies locally a 10 per cent. quinin salve, which he states has a remarkable antiseptic action.

Spinal Cocainization as Treatment of Sciatica.—Manega and Pullé, in Italy, have cured a case of intense pains in the lower members accompanying hemiplegia and one of rebellious sciatic neuralgia, by the subarachnoid injection of 15 mg. of cocain or .75 c.c. of a 2 per cent. solution of cocain. The pains were abolished with a single injection, and have not returned.

The Flap Method of Treating Anthrax.—Sacchetti has successfully treated several severe cases of anthrax by incising the lesion in the shape of an X down to sound tissue below and on each side. The four triangular flaps thus made are turned back, and the surface beneath packed with rolls of gauze moistened copiously with ferric chlorid. The flaps are then replaced, separated from the surface below and from each other by the gauze. The lesion rapidly heals; a dry eschar is thrown off from the surface below, and when a healthy granulating surface is left, the flaps are replaced and sutured, leaving but a minimal scar instead of the extensive defect that usually results.

March 6.

Filiform Bacilli Sign of Malignant Neoplasm of the Stomach. H. Ehret.—When the filiform bacillus is found in great numbers in the stomach, the possibility of a malignant neoplasm must be considered. If this phenomenon is not accompanied by indications of considerable stagnation of the contents of the stomach, it is sufficient ground alone for the diagnosis of carcinoma. In 29 cases in Ehret's experience, in which the great number of these bacilli attracted attention at the first glance, the existence of a malignant neoplasm was established later by the course of the affection in 25, and in the remaining 4 there was almost complete stagnation of the stomach contents from atony or stenosis of the pylorus, and a tumor might have existed unperceived.

Centralblatt f. Gyn. (Leipsic), February 16 and 23.

Difficulty in Extraction of Fetal Skull After Separation from the Trunk. F. Neugebauer.—Seventy cases are reviewed, including a number that have not been published. Even such an expert as Hegar asserts that this complication, in one instance at least, rendered the accouchement the most difficult of all in his experience. It is frequently impossible to grasp the mobile skull. In 4 cases the patient died without extraction of the skull; in 16 the attempt to extract it was abandoned. In 6 instances the skull was spontaneously evacuated later, and in 7 it suppurated out in fragments. In 14 of the 70 cases the patient died. Cesarean section was done 6 times, and was successful in 3 cases. In one of these, Jaeggy experienced the greatest difficulty in extracting the skull from the small pelvis where it had become lodged. Laparotomy was done 11 times with 7 recoveries, and symphyseotomy once. The fetus was putrefied in 9 cases. The skull was separated by decapitation in 14 and torn off in 56 cases, in 23 by the attending physician, once by the woman herself, and once by the husband. Eleven patients were operated on for vesical or rectal fistulæ produced by retained fragments of bone, in one case sixteen years after the delivery. Narath succeeded in curing a patient who had a vesicovaginal and also a jejunovaginal fistula caused by perforation of the uterine wall by a piece of bone after fragmentary removal of the skull of a macerated fetus, one month after death at term. Neugebauer remarks that narcosis is imperative. If manual extraction is not possible, he proceeds at once to perforate the skull, according to Naegele's directions, and extract it with a cranioclast.

Cyst-Formation in Remains of an Ovary. H. Ehrenfest.—The question of neoplasms developing in the fragment of an ovary left after a conservative operation, is one of great interest. Fischer and Waldstein have recently reported cases of this kind, and Martin mentions six. Ehrenfest calls attention to five that have been reported in American literature since 1897.

Cbl. f. Kr. d. Harn u. Sex. (Leipsic), February 9 and March 16.

Syphilitic Cystitis. Chrzelitzer.—The urine was turbid, slightly acid and occasionally blood-stained, but with no sugar indican, gonococci nor tubercle bacilli. Urination was frequent and painful, with retention at times. The patient, a man of 45, denied syphilis and refused narcosis. The tonsils were congested. Local treatment induced merely slight, transient improvement. Finally the testicle showed signs suspicious of syphilis, and under specific treatment the cystitis was promptly and permanently cured. It must have been due to a gummatous lesion in the bladder, the first and only indication of the infection for years.

March 16.

Improved Urethroscopy. N. Nicolai.—The principle of the Welsbach light has been applied to the urethroscope by Nicolai. A very fine platinum wire, coated with thorium oxid, will bear without injury an amount of heat which would consume it without the protective coating. The light afforded is extremely brilliant. It is possible that the thorium takes up the heat and transforms it into light energy.

Deutsche Med. Wochenschrift (Leipsic), March 7.

Treatment of Gangrenous Hernia. W. Petersen.—Between 1877 and 1900, 309 cases of gangrenous hernia were treated at Czerny's clinic; 280 were operated on with a total mortality of 18.5 per cent. Petersen considers the Murphy button and Schleich's infiltration anesthesia the two most important improvements in treatment. The latter is a valuable protection against collapse and obviates aspiration pneumonia, which is the principal danger in operating for gangrenous hernia. Local anesthesia also permits the systematic, thorough evacuation of the contents of the afferent intestine. A long rubber tube is introduced, through which thin feces and gases are soon voided. When this ceases, a pint to a quart of water is allowed to flow into the intestine and this usually straightens it out so that more than three feet of the tube can be worked in. By flushing the intestine in this manner several times, assisted by light massage, incredible amounts of gases and feces are evacuated. The relief experienced by the patient compensates for all the inconveniences of consciousness during the operation. While this is being done the surgeon can be deciding as to the extent and intensity of the gangrenous process. Very recent cases of incarceration do not require such thorough cleansing. By these measures primary resection has become a much less serious operation than it used to be, and should be preferred for all cases of certain gangrene. Before they were introduced primary resection was done 15 times with 8 deaths, a mortality of 60 per cent. Since then it has been done 12 times with only 1 death, or 8 per cent. mortality. An artificial anus is an emergency makeshift. It should never be done except in case of severe collapse or of extensive phlegmons around the hernia. The latter, however, do not necessarily contraindicate primary resection. Reposition is not permissible if there is the slightest suspicion of a gangrenous tendency. Ten of the 18 deaths after reposition were from secondary necrosis of the intestines in the 20 or more cases in which there had been some doubt in regard to the vitality of the tissues, a mortality of 50 per cent. The loop was kept outside for observation in only 3 cases; one required resection later. The grooves where the forceps had been applied became necrotic, which never occurred in Petersen's experience when the intestine was replaced in the peritoneal cavity, and this suggests that the circulation may be unfavorably influenced by this procedure. Reposition was done 216 times, with a mortality of 11 per cent.; artificial anus 22 times, mortality 67 per cent., and primary resection 22 times, mortality 33 per cent. During and since 1898, an artificial anus was made in only 5 cases, with 5 deaths. The proportion of cases in which the operation was responsible for the fatal termination has been reduced from 33 to 12 per cent. during and since 1898. The article is concluded from Nos. 8 and 9 and contains the details of all the cases of primary resection.

Radical Operation for Hernia in Childhood. H. Maass.—During the last five years Maass has operated on 33 children for hernia, about 1 per cent. of all the cases he has had occasion to treat. Under 1 year of age a suitable truss will usually cure the hernia without operation. The tissues in childhood grow so rapidly that a plastic operation is unnecessary under 4, and was not required in any of his operations under 7 years of age. All have been permanently cured, many for more than two years. The child's serosa is so tender and transparent that it is not necessary to open the sac. This reduces the danger of infection. Maass merely pulls out the isolated sac, twists it several times and ligates it at the neck with silk. The wound is closed with iodoformed collodion, without other dressing. The sutures are removed the sixth day and the collodion renewed, which completes the operation. There is little or no general reaction and the local varies with the tender handling of the serosa. The most serious complications were in six cases of vaginal hernia. The principal danger is from the narcosis. In 4 cases there was extraperitoneal infection of the side of the scrotum, requiring drainage and tamponing. In one case the vas deferens or testicular vessels must have been injured, as necrosis of the testicle ensued, requiring its removal ten months afterward. An incarcerated inguinal hernia in a ten-months infant contained no intestine but the entire adnexa of that side, twisted and hemorrhagic. They were excised and the child soon recovered.

Sieve for Feces. Max Einhorn.—An ordinary flour sieve is mounted on a tripod standard and fitted with a cover sloping inward to an aperture in the center. The feces are placed on the sieve, the apparatus placed under the faucet and the handle turned as the water flows through. The feces are thus rubbed smooth and rinsed clean in three to six minutes, with less trouble than with Boas's sieve devised for the purpose (illustrated in The Journal of Oct. 6, 1900, p. 913). The flour sieve can be used alone without further adaptation.

Jahrbuch f. Kinderheilkunde (Berlin), January.

Relations Between Scrofulosis and Tuberculosis. E. Ponfick.—From the etiologic point of view there is a pyogenic scrofulosis, a bacillogenic, and a third mixed variety. Ponfick considers it an open question whether the conception of scrofulosis shall be carried over into the new century or not. It has certainly outlived its meaning as a specific affection, but until a more appropriate term is invented, it still serves to represent that anomaly in the constitution which influences the course of infections and imparts a special character to them. This constitutional disposition depends on the congenital or acquired enhancement of certain features of the childish organism, on the one hand, and on the other, on a congenital, abnormal tendency in the development of certain cell-complexes. It may also depend—but very rarely—on a direct, intrauterine transmission of the pathogenic agent. Future researches will find a fruitful field in the congenital deviations from the normal constitution, which betray a condition of weakness in certain regions of cells.

Purulent Cerebrospinal Meningitis Caused by the Influenza Bacillus. J. Langer.—After eleven days of severe, progressive and rebellious meningitis in a girl of 9, Langer resorted to lumbar puncture. About 8 c.c. of cerebrospinal fluid were withdrawn, which deposited a thick sediment of fibrin and polynuclear leucocytes, many containing influenza bacilli. The temperature dropped to normal immediately after the puncture, as at a crisis, and the patient rapidly recovered. He has noticed the same favorable result in a number of other cases of meningitis.

Wiener Klin. Rundschau, February 17 and 24.

The So-called Sclerotic Atrophy of the Hemispheres. E. Bischoff.—In the two cases reported, of progressive epilepsy with idiocy or dementia, the autopsy showed that one of the cerebral hemispheres was slightly smaller and harder than the other. In every other respect it appeared normal under the microscope and all tests. There was no atrophy nor sclerosis. In both patients and in others that have been reported, the course of the affection and the anatomic findings indicated an original encephalitis restricted to one hemisphere, but evenly generalized in this, and gradually retrogressing to complete anatomic restitution. It imposed, however, a premature limit on the physiologic development of the hemisphere, and left a permanent disposition to epilepsy. The first indications were symptoms of an acute encephalitis between the second and sixth years of age, and paralysis, with or without fever, lasting for days or weeks. The hemiplegia may persist or subside. The subjects later become feeble-minded or idiotic in most cases, and epileptic seizures usually follow after months or years, or may coincide with the first manifestations. In a few cases there was almost complete restitution in the nervous and psychic domain. In Muhr's case there was no epilepsy, merely slight hemiparesis and moral weakness, terminating in insanity. Kast's patient showed no signs of mental deficiency. In Bischoff's first case, and also in one described by Bourneville, and in another by Ollier, there were no marked paralytic symptoms. In his second case, on the other hand, the symptoms deceptively indicated a focal affection in the region of the cortical center for the arm. Spastic paresis and hyperesthesia were noted over the entire left side, explainable by defective functioning of the abnormally small hemisphere. Disturbances of this nature must entail the same symptoms as a diffuse partial interruption of the nerve fibers passing from the peripheral to the central masses of gray matter, as for instance by a tumor. These cases show that the central nervous system requires not only normal brain substance, but also a certain quantitative minimum for its normal functioning. The anatomical findings in these cases are similar to those in Struempell's pseudo-sclerosis, but the clinical course is entirely different.

February 24.

Cure of Lymphangitis with Massage. Batsch.—The advantages of massage in reducing inflammation, aborting phlegmons, and curing lymphangitis and lymphadenitis, have long been proclaimed by Batsch. He now relates a striking personal experience with a very severe lymphangitis, the result of infection from a cut on his finger inflicted while operating on a rectal fistula, and further infected at a five-hour medicolegal autopsy. In less than two hours after the infection had traversed the barrier of the first obstruction in the finer lymphatics, the lymph vessels in the upper arm were engorged with bacteria. He made an opening above and applied the galvanocautery to the wound. The arm and axilla were energetically massaged for one-half to one hour, two or three times a day, lubricating with gray ointment. The massage deprived the bacteria of the quiet necessary for their development, and obviated the danger of obstruction of the lymph vessels with subsequent destruction of tissue. It summoned the leucocytes with their bactericidal enzymes to the region, and distributed the bacteria throughout the circulation so that the entire army of phagocytes could act upon them. The threatening symptoms subsided without abscess formation, in four to five days, but he continued the massage for three weeks, once or twice a day, supplemented by an abundance of nourishing food to meet the extra demands on the blood-forming organs. The fever noticed after the first massage was probably from a chemical reaction due to the dissolving of the bacteria by the alexins secreted by the leucocytes.

Wiener Klin. Wochenschrift, February 28.

Experiences with Cinnamic Acid in the Treatment of Tuberculosis. Pollak and Hodlmoeser.—Pollak reports that in many cases treatment with cinnamic acid, according to Landerer's directions, had an unmistakably favorable effect on the entire course of the disease. It may prove a valuable aid in the treatment of tuberculosis in certain cases, he concludes, but, as a general thing, sanitarium treatment alone is fully as effective. He reports 48 cases of pulmonary tuberculosis thus treated. The results were that 66.7 per cent. were essentially improved, including 12.5 per cent. clinical recoveries, and 20.8 per cent. improved. No benefit was derived in 5 cases of intestinal tuberculosis. Two out of 9 cases of laryngeal tuberculosis were completely cured after the failure of other methods. Another was much improved by a combination of cinnamic and lactic acids. One out-patient with pulmonary tuberculosis was clinically cured by the treatment; another old chronic case, under the same conditions, was not influenced.

he remainder of the patients were inmates of the Alland sani- rium. Hodlmoeser reports 22.2 per cent. of essential im- rovement in 18 patients with pulmonary tuberculosis, includ- g 7 out-patients. Kraemer has collected 186 cases treated y Landerer's method. Of this number 81 were under treat- ent for more than four weeks, with positive results in 72.8 er cent. and negative in 27.2 per cent. Hodlmoeser agrees ith Ewald that the results to date of treatment with cinnamic cid encourage further trials.

Ziegler's Beitraege z. Allg. Path. (Jena), XXIX, 1.

Permeability of Granulating Tissue for Pathogenic Micro-organisms. A. Juergeluenas.—An aseptic, uninjured granulating surface proved a complete mechanical protection against penetration of bacteria in most of the tests reported. Bacteria placed on the granulating surface were not modified n the case of animals susceptible to infection, but on immune animals the bacteria were much altered by the secretions, and killed in the course of six hours. The animals who had not xperienced the slightest harm from anthrax bacilli placed on he granulating surface, rapidly succumbed when they were laced on a fresh wound or injected under the skin. The haracter of the dressings has no influence on the course of the nfection, but the healing processes are less rapid under an air-tight dressing.

Retroperitoneal Hernia. C. Abée.—At the autopsy on a man of 53, who had been received moribund at the hospital, a large hydronephrosis was found, coinciding with an enormous. complete retroperitoneal hernia. Eight of the fifteen similar cases that have been reported were cured by surgical interven- n; the prognosis is better the earlier the diagnosis. In this case the hernia protruded though Treitz's vascular ring, com- posed of the aorta, left colic artery and inferior mesenteric vein.

Zeitschrift f. Hyg. u. Infect. (Leipsic), XXXVI, 1.

Artificial Production of Immunizing and Curing Substance. R. Emmerich and O. Löw.—By the artificial cultivation of bacteria on a large scale, Emmerich and Löw have reaped an extensive harvest of the specific bacteriolytic enzyme which is produced when bacteria are developing on a suitable culture-medium or in the animal organism. The combination of this enzyme with the albumin of the blood or organs, produces the actual, specific immunizing and curative substance, the immun-proteidin, as it is called. They have succeeded in manufacturing this substance on a large scale for swine plague and anthrax. The immunizing and curative results obtained with it have been so successful that they proclaim this agricultural method of obtaining the specific remedy destined to supplant serotherapy for infectious diseases. The medium must require weeks and months. instead of days, for the bacteria to develop in it, in order that the harvest of enzymes reaped may be as abundant as possible. The mixture found most satisfactory is a combination of asparagin, .8 gm.; pepton sicc., 10 gm.; potassium-sodium tartrate, .8 gm.; sodium bicarbonate, 1 to 2 gm.; potassium biphosphate, 2 gm.; magnesium sulphate, .15 gm.; sodium chlorid, 3 gm.; bouillon, 100 gm., and aq. dest., 1000 c.c. The bacilli of swine plague grow slowly on this medium and produce the enzyme, "erysipelase," in abundance. The culture-medium for the bacillus pyocyaneus is nearly the same, omitting the peptone, bicarbonate, tartrate and bouillon and adding sodium acetate. They state that the "pyocyanase" thus derived is a certain cure for anthrax, destroys diphtheria and typhoid bacilli. and it is possible to cure an otherwise fatal intoxication in guinea-pigs by repeated subcutaneous injections of this pyocyanase solution. The media are sown in pint or quart vessels and kept at 25 C., and later at 30 to 37 C. After four or five weeks they are shaken several times a day, and then, after a day's rest, the fluid is aspirated and filtered through a Berkefeld filter. The albumin is added, in the form of fresh beef blood or ground spleens, with .3 per cent. sodium oxalate and .4 per cent. caustic potassium or .3 per cent. potassium carbonate. The mixture is kept at 37 C. for six to eight hours. The finished immun-proteidin thus obtained is a highly molecular, trypsin-proof albuminoid. It is precipitated with ten times the amount of absolute alcohol and made into a powder. The enzyme is also a powder and has been kept for two years without losing any of its properties. The particles of spleen show marked agglutination at first, as in the Widal test.

Gazetta degli Ospedali (Milan), February 24.

Primary Syphilitic Pleurisy. N. De Dominicis.—A syphilitic origin was retrospectively evident in seven cases of primary pleurisy in this writer's experience during the last five years. It was distinguished by its chronic course, commencing with extensive effusion and becoming later extremely hyperplastic, by the absence of high or continuous fever and of acute pains, although there were dull, diffuse pains and progressive dyspnea. This chronic phlogosis may last for years, entailing progressive cachexia, although never severe as in case of a malignant tumor. The affection is rebellious to all ordinary measures, but promptly subsides under mercurial treatment. One of his patients refused to acknowledge syphilitic infection and rejected specific treatment, but the slowly progressive cachexia and dyspnea for three years finally compelled him to yield, and ten injections of succinamid of mercury produced marked improvement, while fifty more cured him completely.

Talma's Operation for Ascites. T. Pozzan.—Ascites accompanying hepatic cirrhosis has been treated, by Talma, by the production of peritoneal adhesions and the fixation of the omentum to the abdominal wall, all for the purpose of establishing collateral circulation. This procedure has been employed in 18 cases by various surgeons, with 5 deaths, 7 patients cured of the ascites, and 6 unmodified by the intervention. Death occurred as the result of shock, peritonitis, interstitial nephritis or marasmus. All the patients operated on were affected with atrophic cirrhosis, and in all the successful cases the general health was improved and the spleen reduced in size, besides the abolition of the ascites. The operation is especially indicated for young subjects in the early stages of the affection, before the liver cells have lost their vitality. It is contraindicated in case of icterus, urobilinuria, acholia or hypocholia. It is by no means a radical cure of atrophic cirrhosis of the liver, but its harmlessness and the successes obtained in certain cases with it justify its more general adoption. A personal case is described, operated on in an advanced, chronic stage of the affection. Improvement was apparent for a time, but the affection continued its course till the patient's death, eleven months later.

Cirugia Contemporanea (Mexico), 1, 1.

Spinal Cocainization. J. Villarreal.—Four cases are cited in which gynecologic operations were performed under the influence of spinal injections of .75 to 1 c.c. of a 2 per cent. solution of cocain. In all but one case the patient complained of pain on traction of the peritoneum, and the anesthesia was completed with a small amount of chloroform. Villarreal suggests that the injection of cocain might be fully as effective for operations on the lower limbs, if made in the cauda equina, while the danger of injuring the cord would be avoided.

Books Received.

Acknowledgement of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits, or in the interest of our readers.

A System of Practical Therapeutics. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Second Edition. Revised and Largely Rewritten. Vol. II. Fevers—Diseases of the Respiratory and Circulatory Systems—Diseases of the Digestive System and Kidneys—Nervous Diseases and Diseases of the Skin. With Illustrations. Cloth. Pp. 926. Price, $5.00 net. Philadelphia and New York: Lea Brothers & Co. 1901.

A Treatise on the Diseases of the Ear, Including the Anatomy and Physiology of the Organ. Together with the Treatment of the Affections of the Nose and Pharynx Which Conduce to Aural Disease. By T. Mark Hovell, F.R.C.S. Edin., M.R.C.S. Eng., Aural Surgeon to the London Hospital. Second Edition. Cloth. Pp. 808. Price, $5.50. Philadelphia: P. Blakiston's Son & Co. 1901.

Hypnotism. A Complete System of Method, Application and Use, Prepared for the Self-Instruction of the Medical Profession. By L. W. De Laurence. Instructor at the School of Hypnotism and

Suggestive Therapeutics, Pittsburg. Illustrated. Cloth. Pp. 256. Price, $1.50. Chicago: The Henneberry Co.

Transactions of the Iowa State Medical Society. Volume XVIII. Forty-ninth Annual Session, 1900. Cloth. Pp. 442. Waterloo, Ia.: Geo. C. Hubbs.

The Medical Missionary Society in China. Annual Report for the Year 1900. Paper. Pp. 33.

Proceedings of the Pathological Society of Philadelphia. March, 1901. Paper. Published by the Society. 1901.

Oral Sepsis as a Cause of "Septic Gastritis," "Toxic Neuritis," and Other Septic Conditions. With Illustrative Cases. By William Hunter, M.D., F.R.C.P., Senior Assistant Physician, the London Fever Hospital. Cloth. Pp. 30. Price, 3/6. London, Paris, New York and Melbourne: Cassell & Co., Ltd. 1901.

Report of the Minister of Agriculture for the Dominion of Canada for the Year Ended October 31, 1900. Printed by order of Parliament. Paper. Pp. 131. Price, 15 cents. Ottawa: S. E. Dawson. 1901.

Sixth Biennial Report of the Board of Trustees of the Delaware State Hospital at Farnhurst. December, 1900. Paper. Pp. 109. Wilmington, Del.: Sunday Star Print. 1900.

Annual Report of the Department of Health, City of Niagara Falls, N. Y., for the Year 1900. Submitted by James H. Meehan, M.D., Health Officer. January, 1901. Paper. Niagara Falls, N. Y.: Cataract Journal Co. 1901.

Cyclic Albuminuria. By G. A. Sutherland, M.D., Physician to Paddington Green Children's Hospital. Paper. Pp. 63. Price, 2s 6d net. London: Clinical Journal Office. 1900.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, War Department, Washington, D. C., March 7 to 13, 1901, inclusive:

Charles Anderson, captain and asst.-surgeon, Vols., recently appointed, to proceed from Fort Brown, Tex., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Robert W. Andrews, lieutenant and asst.-surgeon, 46th Infantry Vols., honorably discharged from the service of the United States, to take effect March 17, 1901.

John E. Bingham, acting asst.-surgeon, now at Walla Walla, Wash., to duty at Fort Walla Walla, relieving Major Walter Whitney, surgeon, Vols.
